34 **Abstract**

35 **Background:** Precise visualization of meshes and their position would greatly aid in
36 mesh shrinkage evaluation, hernia recurrence risk assessment, and the preoperative
37 planning of salvage repair. Lightweight (LW) meshes are able to preserve abdominal
38 wall compliance by generating less post-implant fibrosis and rigidity. However,
39 conventional 3D imaging techniques such as computed tomography (CT) and
40 magnetic resonance imaging (MRI) cannot visualize the LW meshes. Patients
41 sometimes have to undergo a second-look operation for visualizing the mesh
42 implants. The goal of this work is to investigate the potential advantages of
43 Automated 3D breast ultrasound (ABUS) pore texture analysis for implanted LW
44 hernia mesh identification.

45 **Methods:** In vitro, the appearances of four different flat meshes in both ABUS and 2D
46 hand-held ultrasound (HHUS) images were evaluated and compared. In vivo, pore
47 texture patterns of 87 hernia regions were analyzed both in ABUS images and their
48 corresponding HHUS images.

49 **Results:** In vitro studies, the imaging results of ABUS for implanted LW meshes are
50 much more visualized and effective in comparison to HHUS. In vivo, the inter-class
51 distance of 40 texture features were calculated. The texture features of 2D sectional
52 plans (axial and sagittal plane) have no significant contribution for implanted LW
53 mesh identification. Significant contribution was observed in coronal plane. However,
54 since the mesh may have spatial variation such as shrinkage after implant surgery, the

55 inter-class distance of 3D coronal plane pore texture features are bigger than 2D
56 coronal plane, so the contribution of 3D coronal plane pore texture features are more
57 valuable than 2D coronal plane for implanted LW mesh identification. The use of 3D
58 pore texture features significantly improved the robustness of the identification
59 method in distinguishing the LW mesh and fascia.

60 **Conclusions:** An innovative new automated 3D breast ultrasound (ABUS) provides
61 additional pore texture visualization, by separating the LW mesh from the fascia
62 tissues. Therefore, ABUS having the potential to provide more accurate features to
63 characterize pore texture patterns, and ultimately provide more accurate measures for
64 implanted LW mesh identification.

65 **Keywords:** automated 3D breast ultrasound (ABUS), abdominal wall hernia,
66 lightweight mesh, implanted mesh identification, pore texture analysis

67 **Background**

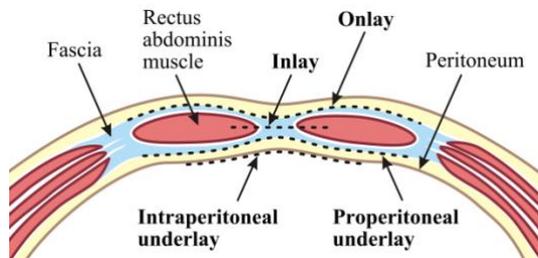

68 Repair of abdominal wall hernias is one of the most frequently performed
69 operations across the world [1-3]. It has been estimated that 250,000 ventral hernia
70 repairs are being done in the USA yearly [4, 5]. Today, most abdominal wall hernias
71 are treated by placement of mesh to repair the abdominal wall defect [6-8]. Several
72 reports have shown that compared with simple sutures, mesh is superior, with
73 significantly reduced recurrence rates [8-11]. However, implanted mesh is a foreign
74 body and is subject to a variety of complications, with recurrence remaining an

75 unsolved problem and reoperation increasingly common [6, 12]. Therefore,
76 sonologists now need perform an increasing number of examinations in patients with
77 previously implanted meshes for either repair-related problems or other indications
78 [1]. For evaluation of these patients, it is important to identify the mesh itself separate
79 from the soft tissues that surround it to confirm a successful reconstruction, identify
80 mesh failure, or better plan a salvage repair [12].

81 Lightweight (LW) mesh with the reduced polypropylene content and larger pore
82 sizes between filaments has demonstrated a pronounced reduction in inflammation
83 and improved integration into surrounding tissue in humans [13]. Based on the
84 development tendency of minimal foreign body left behind, the heavyweight (HW)
85 meshes are being gradually replaced by the LW meshes [14]. The previous studies
86 showed that the LW mesh is not visible on computed tomography (CT) because it is
87 isoattenuating relative to surrounding tissues [1, 15].

88 Although the 2D hand-held ultrasound (HHUS) has been shown to identify
89 radiolucent foreign bodies[12, 16], in our experience, it has not been always reliable
90 in identifying the LW mesh. In ventral hernia repair surgery, mesh may be placed in a
91 variety of locations in relation to the structures of the anterior abdominal wall (Fig. 1),
92 all of which are usually close to the fascia [8, 11]. However, in sectional views (axial
93 and sagittal views) of HHUS, both the LW mesh and fascia are usually rendered as a
94 linear and hyperechoic area [17]. For this reason, the texture features of HHUS
95 images reflect mixed properties of LW mesh overlapping fascia tissues. Fascia could

96 be considered as anatomical noise to implanted LW mesh identification, and therefore
97 reduce the differential diagnosis value of the computed texture features.

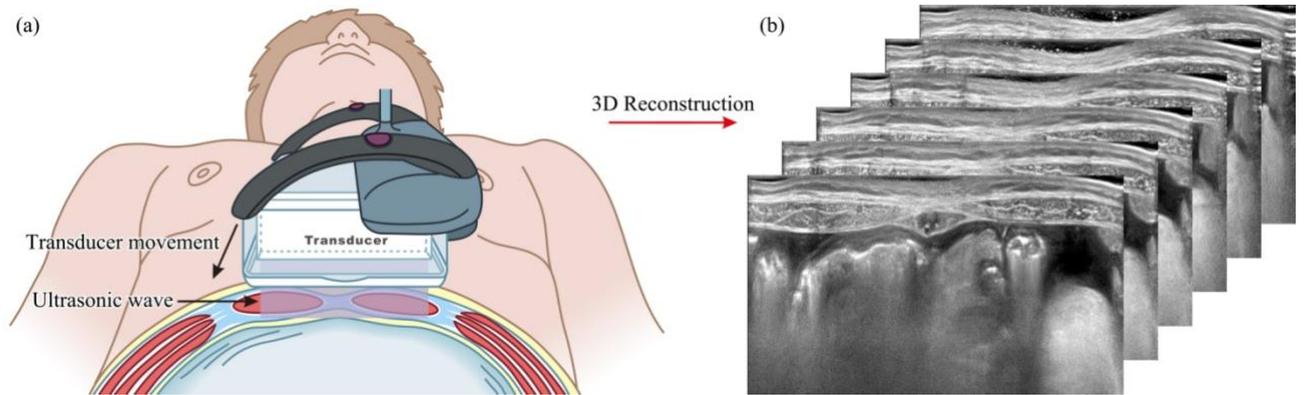

98

99 Fig. 1. Anterior abdominal wall in cross section above the arcuate line. The mesh (black dashed lines)
100 may be anterior to the abdominal wall fascia (Onlay), be adjacent to the fascial edges (Inlay), in the
101 preperitoneal space between the fascia and the peritoneum (Properitoneal underlay), or be attached to the
102 peritoneum in an intraperitoneal position (Intraperitoneal underlay).

103 Automated 3D breast ultrasound (ABUS) is an innovative new ultrasound
104 imaging modality in which tomographic images of the scanning area are reconstructed
105 in 3D from a series of 2D ultrasound images that are acquired by moving a
106 conventional transducer (Fig. 2). Clinical trials have shown that ABUS provides
107 superior tissue visualization and improved lesion conspicuity in comparison to
108 HHUS, resulting in higher sensitivity and specificity [18-20]. As a relatively mature
109 3D ultrasound modality at present, the ABUS has drawn more and more attention of
110 scholars [21]. It is not only widely applied in breast cancer detection, but also rapidly
111 developed in abdominal wall hernias diagnosis [22, 23]. Compared to HHUS sectional
112 views [Fig. 3(a)], ABUS also provides additional diagnostic information from coronal
113 views, which cannot be generated by the 2D ultrasound [18]. The new coronal plane
114 offers superior pore texture visualization, by separating the LW mesh from the fascia
115 tissues [Fig. 3(b-c)]. Therefore, ABUS could offer the ability to selectively analyze

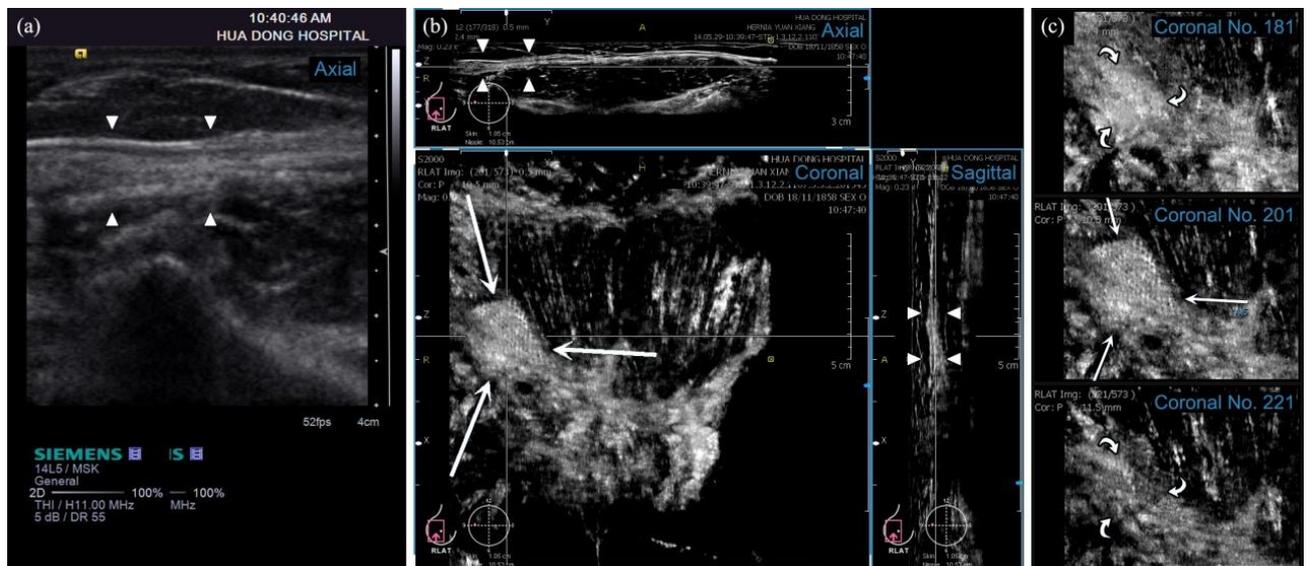

116 the texture features of the LW mesh, having the potential to provide more accurate
 117 features to characterize pore texture patterns, and ultimately provide more accurate
 118 measures for implanted LW mesh identification.

119

120 Fig. 2. An illustrative example of (a) automated 3D breast ultrasound (ABUS) acquisition geometry with
 121 (b) the reconstructed tomographic anterior abdominal wall image.

122

123

124 Fig. 3. Differences of texture features in (a) the axial view of HHUS, (b) the three orthogonal views of
 125 ABUS and (c) coronal multislice views of ABUS for the same LW mesh. Note that the texture features
 126 of HHUS images reflect mixed properties of LW mesh overlapping fascia tissues. Therefore, it is difficult
 127 to identify the LW mesh itself separate from the fascia tissues that surround it (arrowheads). However,
 128 the new coronal plane of ABUS offers superior pore texture visualization, by separating the LW mesh
 129 (arrows) from the fascia (curved arrows) tissues.

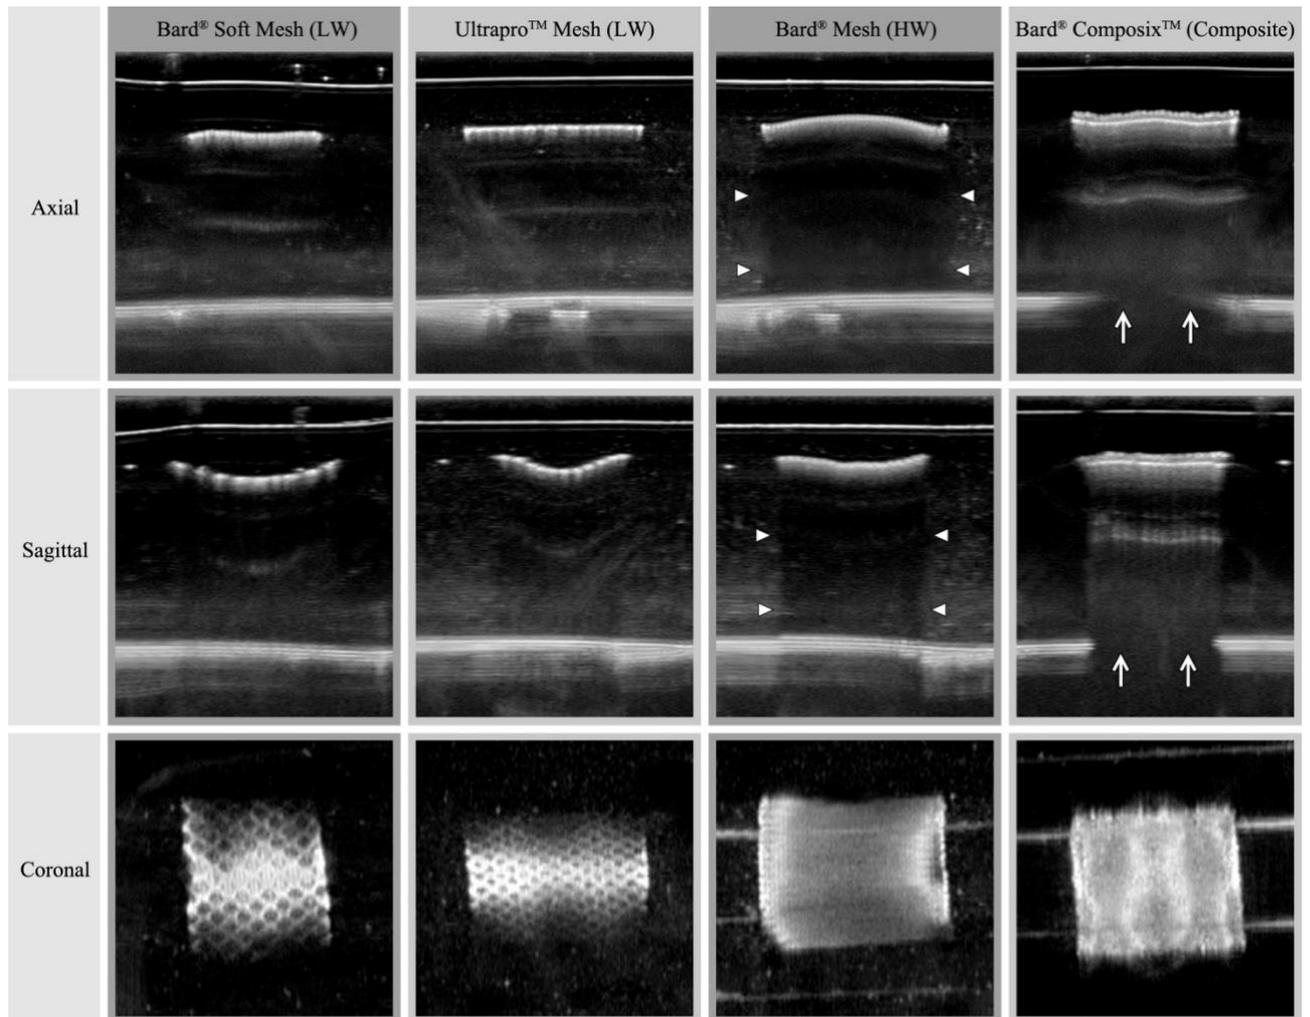

130 In this paper we present an exploratory study that investigates the potential
131 advantages of ABUS pore texture analysis for implanted lightweight hernia mesh
132 identification. In vitro, the appearances of four different flat meshes in both ABUS
133 and HHUS images were evaluated and compared. In vivo, pore texture patterns of 87
134 hernia regions were analyzed both in ABUS images and their corresponding HHUS
135 images. The presence of the previously implanted lightweight mesh in the hernia
136 region was identified by using both ABUS and HHUS texture features. We compared
137 the relative identification performance of ABUS and HHUS texture features in
138 correlating with the established surgical findings. Although preliminary, our results
139 suggest that ABUS pore texture analysis could potentially provide more
140 discriminative features for implanted lightweight hernia mesh identification, in
141 comparison to HHUS images. To the best of our knowledge, our study is the first to
142 investigate the potential advantages of ABUS pore texture analysis for implanted
143 lightweight hernia mesh identification, with the intention to offer instrumental
144 evidence for the design of larger clinical studies in the future. The improved
145 performance and low cost of ABUS will likely fuel the rapid and broad dissemination
146 of ABUS as an implanted lightweight hernia mesh imaging modality.

147 **Results**

148 **a. In vitro study**

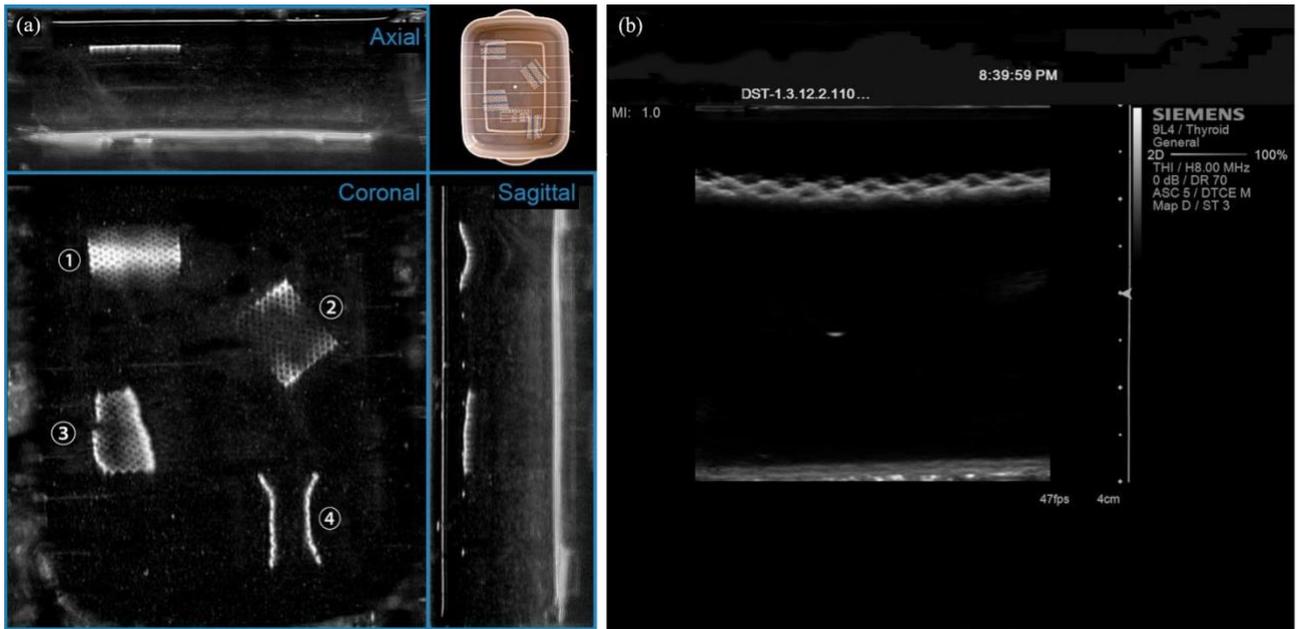

149 The ABUS imaging comparisons of four tested meshes are shown in Fig. 4. As
150 an example, the three orthogonal plan views of ABUS imaging of the Ultrapro™

151 Mesh box are shown in Fig. 5 (a). In comparison, the HHUS imaging result (axial
 152 plane) is shown in Fig. 5 (b). The 3D volume rendering results based on ABUS scan
 153 data of the Ultrapro™ Mesh box are shown in Fig. 6, and the results of ABUS
 154 imaging of Ultrapro™ Mesh fragments No. 1 to No. 4 are shown in Fig. 7.

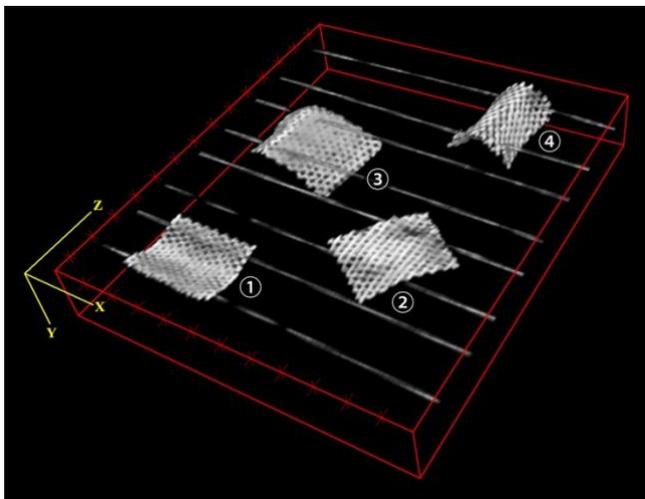

155

156 Fig. 4. ABUS imaging comparisons of four tested meshes. The four columns show the Bard® Soft Mesh
 157 (LW), the Ultrapro™ Mesh (LW), the Bard® Mesh (HW), and the Bard® Composix™ Mesh (Composite)
 158 in three orthogonal views, respectively. Note that both LW Bard® Soft and LW Ultrapro™ meshes are
 159 shown in the coronal plane with distinct pore texture. The HW Bard® mesh is shown in sectional views
 160 (axial and sagittal views) with posterior acoustic shadowing (arrowheads). The Composite Bard®
 161 Composix™ mesh is shown in sectional views (axial and sagittal views) with badly posterior acoustic
 162 shadowing, and the bottom of the plastic container has been unable to observe by ultrasonography
 163 (arrows).

164

173

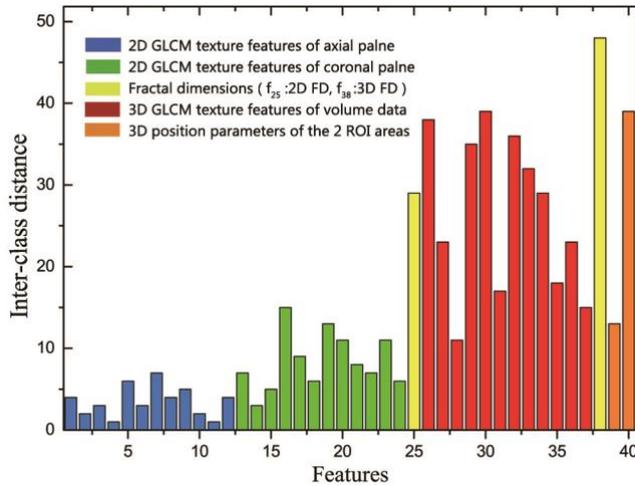

174

175 Fig. 7 The results of ABUS imaging of Ultrapro™ Mesh (LW) with four mesh fragments. Note that
 176 fragment No. ① is parallel to the horizontal plane, fragment No. ② is rotated a certain angle in the
 177 horizontal plane, fragment No. ③ is rotated a certain space angle in the depth direction of the horizontal
 178 plane, and fragment No. ④ is curved to represent the shrinkage of the mesh. Note that the fragments
 179 No. ①-④ are used to simulate the mesh spatial variation that may occur after implantation.

180 **b. In vivo study**

181 The calculation results of the inter-class distance for all 40 pore texture features
 182 are shown in Fig. 8. The distinction rate between fascia and mesh is directly
 183 proportional to the size of parameter values of inter-class distance.

184

185 Fig. 8. The inter-class distance results of all 40 pore texture features.

186 **Discussion**

187 Precise visualization of meshes and their position would greatly aid in hernia
 188 recurrence risk assessment and the preoperative planning of salvage repair. However,
 189 since LW meshes have very thin thickness and large pore sizes between filaments,
 190 conventional 3D imaging techniques such as CT and MRI cannot visualize the LW
 191 meshes [1]. Patients sometimes have to undergo a second-look operation for
 192 visualizing the mesh implants[3]. An innovative new automated 3D breast ultrasound
 193 (ABUS) provides additional diagnostic information from coronal views, which cannot
 194 be generated by the 2D ultrasound [18]. The new coronal plane offers superior pore
 195 texture visualization, by separating the LW mesh from the fascia tissues. From the
 196 Fig. 4, 5, 6 and 7, it can be seen that the imaging results of ABUS for implanted LW
 197 meshes are much more visualized and effective in comparison to HHUS. This is due
 198 to the high resolution of ABUS imaging, and its unique coronal plane provides
 199 additional diagnostic information for us.

200 Heavyweight (HW) meshes and composite meshes have large thickness and
201 weight, small pore sizes between filaments or even no pore. For this reason, these two
202 types of meshes can be observed by conventional 3D imaging methods (CT and
203 MRI). While in ABUS condition, as shown in Fig. 4, the HW and composite meshes
204 also can be observed by ABUS, the reason is that the conventional HW and composite
205 mesh most commonly appears as a linear hyperechoic interface with posterior
206 acoustic shadowing. This appearance can provide the radiologist the ability to easily
207 see the mesh in axial and sagittal views.

208 As shown in Fig. 5, the imaging result of HHUS for lightweight mesh is very
209 similar to the axial and sagittal plane of ABUS. However, the scanning area of HHUS
210 is very narrow, and the radiologist needs to manually integrate multiple images. While
211 in ABUS condition, since the ABUS has a wide field of view; thus, it can display the
212 entire abdominal wall area at once without missing any parts and allows the
213 radiologist to perceive the implanted LW mesh easily.

214 From the Fig. 6 and 7, it can be seen that even if there is a spatial variation after
215 the LW mesh implantation, the unique coronal view of ABUS imaging can be used to
216 provide the spatial variation visualization of implanted LW mesh. As shown in Fig. 6
217 (The 3D volume rendering results based on ABUS scan data of the Ultrapro™ Mesh
218 box), the ABUS can clearly observe the appearance of the implanted LW mesh after
219 spatial variation.

220

221 In vivo study, Fig. 8 shows the inter-class distance results of all 40 pore texture
222 features. From the blue, green and red strip regions of Fig. 8 we can see that the inter-
223 class distance of 2D axial plane texture features (blue strip regions) are generally
224 smaller than others. The reason is that the fascia and LW mesh are approximately
225 presented as a linear bright strip in axial plane view, with little discrimination. Then,
226 compared with the axial plane, the inter-class distance of 2D coronal plane texture
227 features (green strip regions) are higher. The reason is that the LW mesh presents a
228 unique mesh texture in the coronal plane view and offers superior pore texture
229 visualization. However, due to the mesh may have spatial variation such as the curl
230 and shrinkage after implantation, the contribution of 2D coronal plane texture features
231 to LW mesh and fascia identification is not significant. Finally, the inter-class distance
232 of 3D coronal plane texture features are greatly increased compared with 2D coronal
233 plane. The reason is that the use of 3D pore texture features significantly improved the
234 effectiveness and robustness of the identification method in distinguishing the LW
235 mesh and fascia.

236 As shown in Fig. 8 (yellow strip regions), since the fractal dimension (FD)
237 feature is more suitable for the analysis of the mesh texture, the inter-class distance of
238 2D FD and 3D FD features are higher than other inter-class distance of features. The
239 inter-class distance of 3D FD feature reaches the maximum value in the inter-class
240 distance of 40 features, which fully reflects that FD features can effectively distinguish
241 LW meshes from fascia.

242 As shown in Fig. 8 (orange strip regions), firstly, although the four tension-free
243 meshes placement positions were located at a scan depth of 1-3 *cm* and the fascia in
244 this area has a higher probability of occurrence, the effect of feature f_{39} (local feature)
245 based on scanning depth to LW mesh and fascia identification is unsatisfactory.
246 Secondly, for recurrent cases of abdominal wall hernia, the repair location of the
247 original abdominal wall hernia is the high incidence of recurrent hernia, thus, the
248 closer to the hernia sac, the higher occurrence of mesh. Therefore, the feature f_{40}
249 (environmental feature) based on the coronal plane position in the region of interest
250 (ROI) can distinguish the LW mesh and the fascia significantly, and it's inter-class
251 distance ranks the third in the inter-class distance ordering of all 40 features.

252 The 25 features with the high distinction for fascia and mesh were selected
253 according to the order of inter-class distance from large to small, in order to reduce
254 the feature dimension of subsequent classification recognition, improve classification
255 accuracy and reduce classification working time.

256 Our results provide compelling evidence that ABUS having the potential to
257 provide more accurate features to characterize pore texture patterns. ABUS can
258 provide a broader view which is more convenient for sonologists to observe the entire
259 mesh at one time. Meanwhile, because ABUS can provide more intuitive and easy
260 understood 3D information, sonologists do not need to reconstruct the spatial structure
261 of 3D LW mesh manually in their mind.

262

263 Our study, nevertheless, has certain limitations. The small sample size does not
264 provide sufficient statistical power to connote general applicability of our results and
265 to fully determine the superiority of the 3D versus the 2D pore texture analysis
266 methods. However, since this is the first study to explore the pore texture analysis in
267 ABUS images for implanted lightweight hernia mesh identification, our intention was
268 to evaluate proof-of-concept and demonstrate the instrumental evidence required to
269 initiate the design of large clinical studies in the future. Such larger studies will render
270 the sufficient statistical power required to fully evaluate the potential advantages of
271 ABUS imaging in LW mesh identification.

272 **Conclusions**

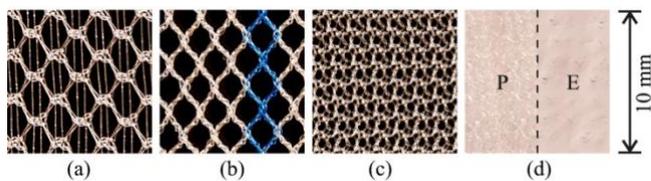

273 Although preliminary, our results suggest that the mesh pore texture provided by
274 ABUS in the coronal plane is particularly effective in assessing the presence of
275 implanted lightweight meshes. Compared to HHUS imaging, ABUS having the
276 potential to provide more accurate features to characterize mesh pore texture patterns
277 and ultimately provide more accurate measures for implanted LW mesh identification.

278 **Materials and methods**

279 **a. In vitro study**

280 In vitro study, four different flat meshes (Fig. 9) was tested. Table 1 shows the
281 basic descriptive data about the four tested meshes. For each tested mesh, 4 fragments
282 [Fig. 10(a), fragments No. ①-④] were used to simulate the mesh spatial variation

283 that may occur after implantation. First, cotton threads were used to control and fix
 284 mesh fragments gesture in a plastic container [Fig. 10(a)]. Then, the plastic container
 285 filled with gelatin [Fig. 10(b)]. Finally, HHUS and ABUS imaging were performed
 286 separately, and the imaging results were evaluated and compared by 2 experienced
 287 board-certified radiologists. Fig. 10(c) shows the experimental equipment of in vitro
 288 study.

290 Fig. 9. The top view of four tested meshes. Each photograph shows a 10 mm wide piece of the mesh
 291 material. (a) Bard® Soft Mesh (LW); (b) Ultrapro™ Mesh (LW); (c) Bard® Mesh (HW); (d) Bard®
 292 Composix™ Mesh (Composite). This composite mesh is constructed of polypropylene mesh on one side
 293 (P), bonded with expanded polytetrafluoroethylene (ePTFE) on the other (E).

294 Table 1. Basic descriptive data about the four tested meshes.

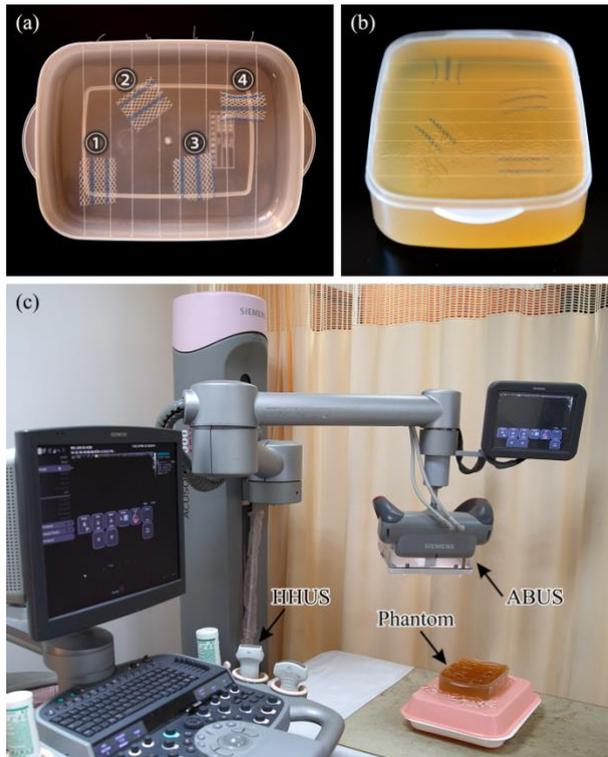

Brand name	Bard® Soft Mesh	Ultrapro™ Mesh	Bard® Mesh	Bard® Composix™ Mesh
Mesh type	Lightweight (LW)	LW	Heavyweight (HW)	Composite
Manufacturer	Bard Davol Inc.	Ethicon, Johnson & Johnson	Bard Davol Inc.	Bard Davol Inc.
Material	polypropylene	polypropylene-poliglecaprone	Polypropylene	polypropylene-ePTFE
Area weight	40 g/m ²	50 g/m ²	102 g/m ²	250 g/m ²
Thickness	0.5 mm	0.5 mm	1.0 mm	2.0 mm
Pore size	3.5 mm	3 mm	1 mm	n/a
Maximum Pressure	n/a	525 mmHg	1650 mmHg	n/a
Instructions by manufacturer	Lightweight mesh designed for open and laparoscopic hernia repair	Partially absorbable lightweight mesh for abdominal wall reinforcement	Conventional polypropylene heavyweight mesh for strong repair	Composite mesh with clinically proven materials to mitigate the risk of visceral adhesion

 302 fragments No. ①-④ are used to simulate the mesh spatial variation that may occur after implantation.

303 b. In vivo study

304 1. Study population

305 From December 2018 to September 2019, 87 patients (56 male and 31 female;
 306 age range, 43–79 years; mean age \pm SD, 60.6 ± 11.2 years) were recruited for the in
 307 vivo study. The study was approved by the Ethics Committee of Huadong Hospital.
 308 All patients were volunteers who signed informed consent. The patients were referred
 309 to our ultrasound department for specific diagnostic queries, such as erythema,
 310 swelling, pain in the hernia region, intensified screening for symptoms suspicious for
 311 hernia recurrence, and preoperative diagnosis. All patients underwent HHUS and
 312 ABUS examinations in the hernia region. To obtain the evaluation criteria for

313 confirming the lightweight mesh identified with ABUS and HHUS pore texture
314 features, only the patients who subsequently underwent surgery were considered in
315 our study. On the basis of the surgical findings, 38 of these patients (44%) with
316 previously implanted lightweight hernia mesh constituted the case group, and 49
317 patients (56%) with no implanted lightweight hernia mesh constituted the control
318 group. After anonymization, the HHUS and ABUS dataset was then available for
319 further study.

320 **2. Examination methods (HHUS vs. ABUS)**

321 The HHUS examinations were performed by a radiologist with five years'
322 experience in abdominal wall hernia sonography using an ACUSON S2000
323 ultrasound system (Siemens Medical Solutions, Mountain View, CA, USA). The
324 patients were placed in the supine position for the examination. The Static 2D images
325 were obtained using a 14L5 linear array transducer at 11 MHz central frequency.
326 Images in axial and sagittal planes that best manifested the central hernia region were
327 stored on an offline workstation for review and analysis.

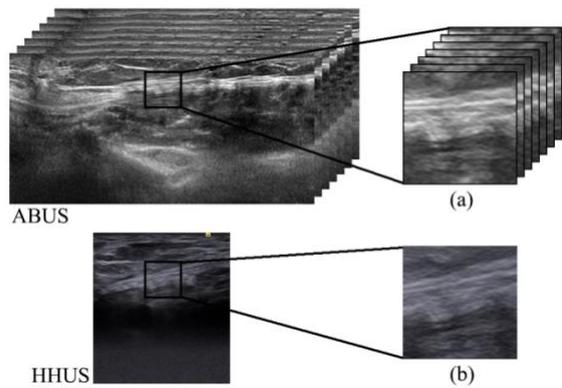

328 The ABUS examinations were performed also on Siemens ACUSON S2000 by
329 the same radiologist, but with a 14L5BV linear transducer. The central frequency of
330 transducer varied from 9 to 11 MHz. The frequency was set at 11 MHz for the present
331 study. This transducer is able to capture a volume of $154 \times 168 \times 60 \text{ mm}^3$ in a single
332 scan. In each scanning, the ABUS generates 318 2D slices with a layer thickness of
333 0.5 mm in axial direction. ABUS examinations were performed with the patients lying

334 in the same position as they were for the HHUS scanning. Before scanning, the
335 radiologist applied appropriate pressure to the transducer to keep the probe closely
336 attached to the central hernia region surface [Fig. 2(a)]. After acquisition, the volume
337 data sets were automatically sent from the ultrasound system to the diagnostic
338 workstation, which enabled comprehensive analysis and manipulation of the 3D data.

339 **3. Image analysis**

340 A region of interest (ROI) was manually segmented from the central hernia
341 region in each image. The physical dimensions of the ROIs were selected to be 10
342 mm^3 for the ABUS images, and 10 mm^2 for the HHUS images, based on previous
343 suggestions for the average pore size of LW mesh in the literature [13]. Corresponding
344 to these physical dimensions, $143 \times 143 \times 19$ pixel ROIs at 0.07 mm /pixel in-plane
345 resolution and 0.53 mm tomographic slice spacing were segmented from all the
346 reconstructed ABUS images; matching 143×143 pixel ROIs at 0.07 mm /pixel
347 resolution were segmented in the corresponding HHUS images of the same central
348 hernia region. Examples of such ROIs are shown in Fig. 11.

349

350

351 Fig. 11. An illustrative example of (a) a 3D ROI segmented from a reconstructed automated 3-D breast
 352 ultrasound (ABUS) image and (b) the corresponding 2D ROI from the hand-held ultrasound (HHUS) of
 353 the same central hernia region.

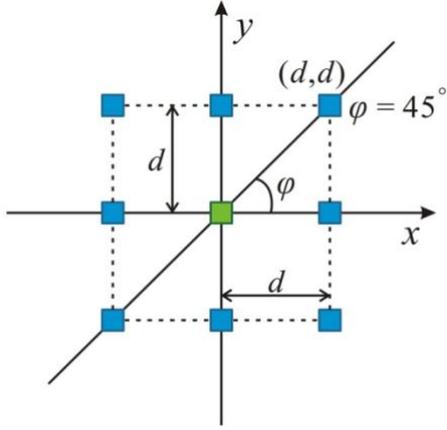

354 To characterize the pore texture pattern, texture features of energy, contrast,
 355 correlation, variance, homogeneity, sum average, entropy, autocorrelation,
 356 dissimilarity, cluster shade ,cluster prominence, maximum probability and fractal
 357 dimension (FD) were estimated from all the ABUS and HHUS ROIs. These texture
 358 features were originally defined for the analysis of 2D images. While texture analysis
 359 method have been widely implemented for the analysis of 2D medical images [24],
 360 the available techniques for 3D pore texture analysis are currently limited. Recently
 361 YAHIA Samah et al. demonstrated an efficient method for the analysis of textures in
 362 the 3-dimensional space [25]. In our study, two approaches were implemented for
 363 pore texture analysis in the 3D reconstructed ABUS images: tomographic (2D) and
 364 volumetric (3D) texture analysis [26].

365 4. Tomographic (2D) texture analysis

366 The gray level co-occurrence matrix (GLCM) is one of the most known texture
 367 analysis operators. Based on measuring texture features, this operator computes the

368 order of co-occurrence of pixels pairs at a certain direction and distance [25]. Haralick
369 et al. defined gray level co-occurrence matrix [27]. We give a uniform definition of
370 gray-level co-occurrence matrix for both 2D and 3D data. Consider an image (either
371 2D or 3D) which is rebound to G gray levels where G is a positive integer. The
372 difference of spatial locations of two pixel points (2D) or two voxels (3D) in an image
373 can be described by a displacement vector D . For an image of G gray levels, the $G \times$
374 G gray level co-occurrence matrix P_{ij} for a displacement vector D is defined as
375 follows. The entry (i, j) of P_{ij} is the number of occurrence of voxel-pair of gray levels
376 i and j whose spatial locations are a vector D apart. When normalized by the total
377 counts, the entry (i, j) of P_{ij} , denoted as $P(i, j)$, represents the probability of
378 occurrence of voxel pair of gray levels i and j whose spatial locations are a vector D
379 apart. In this definition, the co-occurrence matrix P_{ij} is a function of the displacement
380 vector D which can be decomposed into a norm-1 distance d and a direction. Thus, P_{ij}
381 describes distributions of certain spatial patterns of scale d in a certain direction.[28]

382 In 2D images, the difference of spatial locations of two pixel points can be
383 described by displacement vector $D(\varphi, d)$, where φ is the angle of two pixel points and
384 the coordinate axis, and d is the distance between two pixel points. For 2D images, the
385 possible spatial relations of a pair of pixels are shown in Fig.12. Given a certain
386 distance d , there are eight neighboring pixel pairs in four independent directions:
387 horizontal, vertical, diagonal and anti-diagonal (corresponding to 0° , 90° , 45° and
388 135° , respectively).

389

390 Fig. 12. Spatial relations of a pair of pixels in 2D. For a particular pixel (green), it has eight neighboring
 391 pixels (blue) of norm-1 distance d in 4 independent directions.

392 Haralick et al. proposed 14 texture features, twelve of these features were selected
 393 in our study, including energy (f_1), contrast (f_2), correlation (f_3), variance (f_4),
 394 homogeneity (f_5), sum average (f_6), entropy (f_7), autocorrelation (f_8), dissimilarity
 395 (f_9), cluster shade (f_{10}), cluster prominence (f_{11}), maximum probability (f_{12}). The co-
 396 occurrence frequencies were calculated symmetrically in the four independent
 397 directions around each pixel using a displacement vector $D = (dx, dy)$ along x and y
 398 dimensions, where $dx = dy = 1$ pixel offset [26]. The texture features calculated in each
 399 of these four independent directions were averaged to create a single measure that was
 400 used in our experiments.

401
$$f_1 = \sum_i \sum_j P(i, j)^2 \tag{1}$$

402
$$f_2 = \sum_{n=0}^{N_g-1} n^2 \left\{ \sum_{i=1}^{N_g} \sum_{j=1}^{N_g} P(i, j) \|i - j\| = n \right\} \tag{2}$$

$$f_3 = \frac{\sum_i \sum_j (i \cdot j) P(i, j) - \mu_x \mu_y}{\sigma_x \sigma_y} \quad (3)$$

$$f_4 = \sum_i \sum_j (i - \mu)^2 P(i, j) \quad (4)$$

$$f_5 = \sum_i \sum_j \frac{P(i, j)}{1 + (i - j)^2} \quad (5)$$

$$f_6 = \sum_{i=2}^{2N_g} iP_{x+y}(i) \quad (6)$$

$$f_7 = -\sum_i \sum_j P(i, j) \log(P(i, j)) \quad (7)$$

$$f_8 = \sum_i \sum_j (i \cdot j) P(i, j) \quad (8)$$

$$f_9 = \sum_i \sum_j |i - j| \cdot P(i, j) \quad (9)$$

$$f_{10} = \sum_i \sum_j (i + j - \mu_x - \mu_y)^3 P(i, j) \quad (10)$$

$$f_{11} = \sum_i \sum_j (i + j - \mu_x - \mu_y)^4 P(i, j) \quad (11)$$

$$f_{12} = \text{MAX}_{i,j} P(i, j) \quad (12)$$

413 Where $P(i, j)$ is the normalized gray level co-occurrence matrix. The average value and

414 standard deviation of the rows and columns of matrix are:

$$\mu_x = \sum_i \sum_j iP(i, j) \quad (13)$$

$$\mu_y = \sum_i \sum_j jP(i, j) \quad (14)$$

417
$$\sigma_x = \sum_i \sum_j (i - \mu_x)^2 P(i, j) \quad (15)$$

418
$$\sigma_y = \sum_i \sum_j (j - \mu_y)^2 P(i, j) \quad (16)$$

419 Fractal dimension (FD) was estimated based on the power spectrum of the
 420 Fourier transform of the image [26]. The 2D Discrete Fourier Transform (DFT) was
 421 performed using the Fast Fourier Transform (FFT) algorithm as:

422
$$F(u, v) = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} I(m, n) e^{-j(2\pi/M)um} e^{-j(2\pi/N)vn}, \quad \mu = 0, 1, \dots, M-1; \nu = 0, 1, \dots, N-1$$

 423 (17)

424 Where I is the 2D image region of size (M, N) , and μ and ν are the spatial frequencies
 425 in the x and y directions. The power spectral density P was estimated from $F(\mu, \nu)$ as:

426
$$P(u, \nu) = |F(u, \nu)|^2 \quad (18)$$

427 Finally, in order to compute the 2D FD, P was averaged along the radial slices
 428 direction across the FFT frequency domain. The frequency space was uniformly
 429 divided in 24 directions, with each direction uniformly sampled at 30 points along the
 430 radial component. The least-squares-fit of the $\log(P_f)$ versus $\log(f)$ was estimated,
 431 where $f = \sqrt{u^2 + \nu^2}$ denotes the radial frequency. The 2D FD is related to the slope
 432 β of the logarithmic curve in the following form:

433
$$FD = \frac{3D_T + 2 - \beta}{2} = \frac{8 - \beta}{2} \quad (19)$$

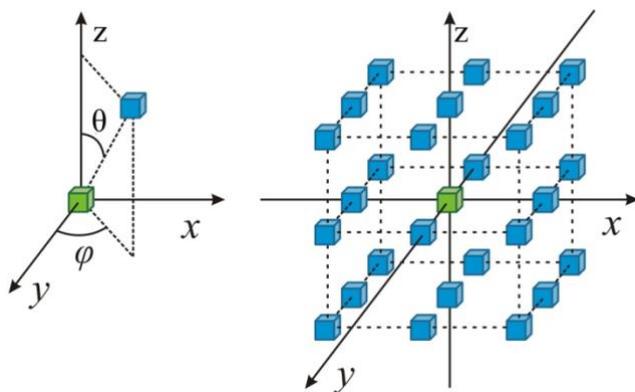

434 Where D_T is the topological dimension, and is equal to $D_T = 2$ for a 2D image.

435 **5. Volumetric (3D) texture analysis**

436 When calculating gray-level pore texture statistics, traditional 2D texture
437 descriptors were extended to 3D by considering a 3D neighborhood of voxels (i.e.,
438 volume elements) instead of a 2D neighborhood of pixels.

439 In 3D images, the difference of spatial locations of two voxels can be described
440 by a displacement vector $D(\varphi, \theta, d)$, where φ and θ is the azimuth and the zenith angle
441 respectively, and d is the distance between two voxels (Fig. 13 left). As shown in Fig.
442 13, there are totally 26 neighboring voxel-pairs in 13 independent directions. Here, it
443 is still selected to extract the same 12 3D GLCM texture features as in 2D GLCM.
444 The 3D displacement vector $D = (d_x, d_y, d_z)$ was defined around each voxel along the
445 x, y and z dimensions, where $d_x = d_y = d_z = l$ is the voxel offset. Texture features were
446 calculated in each of these 13 directions and they were averaged to create a single
447 measure that was used in our experiments.

448

449

450 Fig. 13. Spatial relations of a pair of voxels in 3D. For a particular voxel (green), it has 26 neighbors
451 (blue) of norm-1 distance d in 13 independent directions.

452 Fractal dimension (FD) was estimated based on the power spectrum of the 3D
 453 Fourier transform of the image. FFT algorithm was used to perform 3D DFT for the
 454 entire 3D ROI area:

$$455 \quad F(u, v, w) = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} \sum_{k=0}^{K-1} I(m, n, k) e^{-j(2\pi/M)um} e^{-j(2\pi/N)vn} e^{-j(2\pi/K)wk} \quad (20)$$

456 Where I is the 3D image region of size (M, N, K) , and u, v and w are the spatial
 457 frequencies in the x, y and z directions respectively. The power spectral density P was
 458 estimated as:

$$459 \quad P(u, v, w) = |F(u, v, w)|^2 \quad (21)$$

460 Finally, in order to calculate 3D FD, P was averaged along the radial sector
 461 direction across the 3D FFT frequency domain. The frequency space was uniformly
 462 divided in 24 azimuth directions and 12 zenith angles, with each direction uniformly
 463 sampled at 30 points along the radial component. The least-squares-fit of the $\log(P_f)$
 464 versus $\log(f)$ was estimated, where $f = \sqrt{u^2 + v^2 + w^2}$ represents the radial frequency,
 465 2D FD was related to the slope β of the logarithmic curve in the following form:

$$466 \quad FD_{3D} = \frac{3D_T + 2 - \beta}{2} = \frac{11 - \beta}{2} \quad (22)$$

467 Where D_T is the topological dimension, and is equal to $D_T = 3$ for 3D image.

468 **6. Pore texture analysis for implanted lightweight hernia mesh identification**

469 We performed pore texture analysis on the 2D ROIs of HHUS and 3D ROIs of
 470 ABUS. First, all 40 pore texture features that mentioned earlier were extracted for

471 each ROI region. The extracted pore texture features include 25 2D features, 13 3D
472 features, one local feature (f_{39}) based on the scanning depth of ROI region and one
473 environmental feature (f_{40}) based on the relationship between ROI region and hernia
474 sac location. Then, the inter-class distance of each pore texture was calculated.
475 Finally, the differences of inter-class distance were analyzed for selecting more
476 discriminative features.

477

478 **List of abbreviations**

479 **2D, 3D:** two, three dimensional

480 **ABUS:** automated 3D breast ultrasound

481 **CT:** computed tomography

482 **DFT:** discrete fourier transform

483 **FD:** fractal dimension

484 **FFT:** fast fourier transform

485 **GLCM:** gray level co-occurrence matrix

486 **HHUS:** hand-held ultrasound

487 **HW:** Heavyweight

488 **LW:** Lightweight

489 **MRI:** magnetic resonance imaging

490 **ROI:** region of interest

491 **Declarations**

492 **Ethics approval and consent to participate**

493 The study was approved by the Ethics Committee of Huadong Hospital. All patients
494 were volunteers who signed informed consent.

495 **Consent for publication**

496 Not applicable.

497 **Availability of data and material**

498 The datasets used and/or analysed during the current study are available from the
499 corresponding author on reasonable request.

500 **Competing interests**

501 The authors declare that they have no competing interests.

502 **Funding**

503 This work was supported by the Grant (61661050, 61561050) from the Natural
504 Science Foundation of China and Priority Union Foundation of Yunnan Provincial
505 Science and Technology Department and Kunming Medical University (2018FE001(-
506 143)).

507 **Authors' contributions**

508 JY implemented the draft and analyzed the data. HL and JW suggested the proposed
509 algorithm. YW and YZ was responsible for theoretical guidance. LS, YC, DX and LC
510 implemented the experiments. All authors read and approved the final manuscript.

Figures

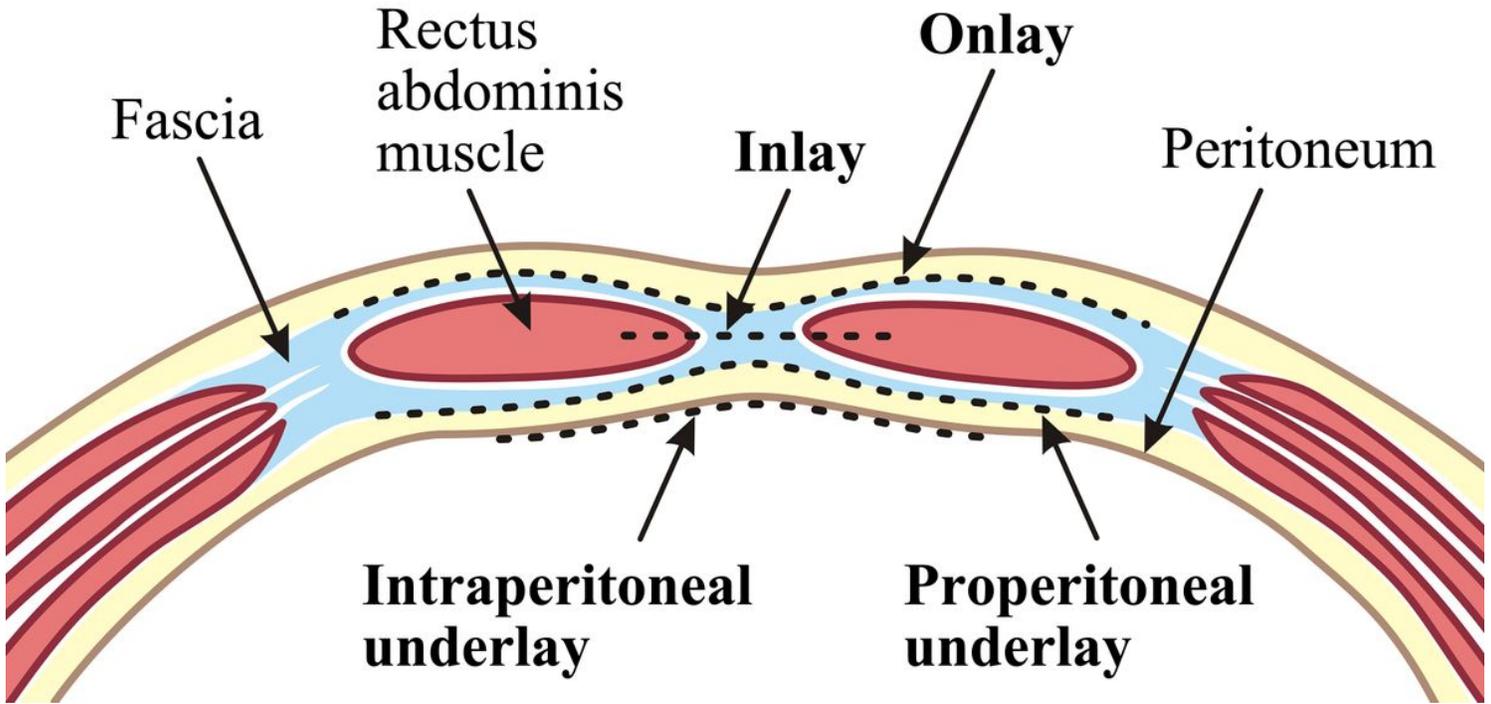

Figure 1

Anterior abdominal wall in cross section above the arcuate line. The mesh (black dashed lines) may be anterior to the abdominal wall fascia (Onlay), be adjacent to the fascial edges (Inlay), in the preperitoneal space between the fascia and the peritoneum (Properitoneal underlay), or be attached to the peritoneum in an intraperitoneal position (Intraperitoneal underlay).

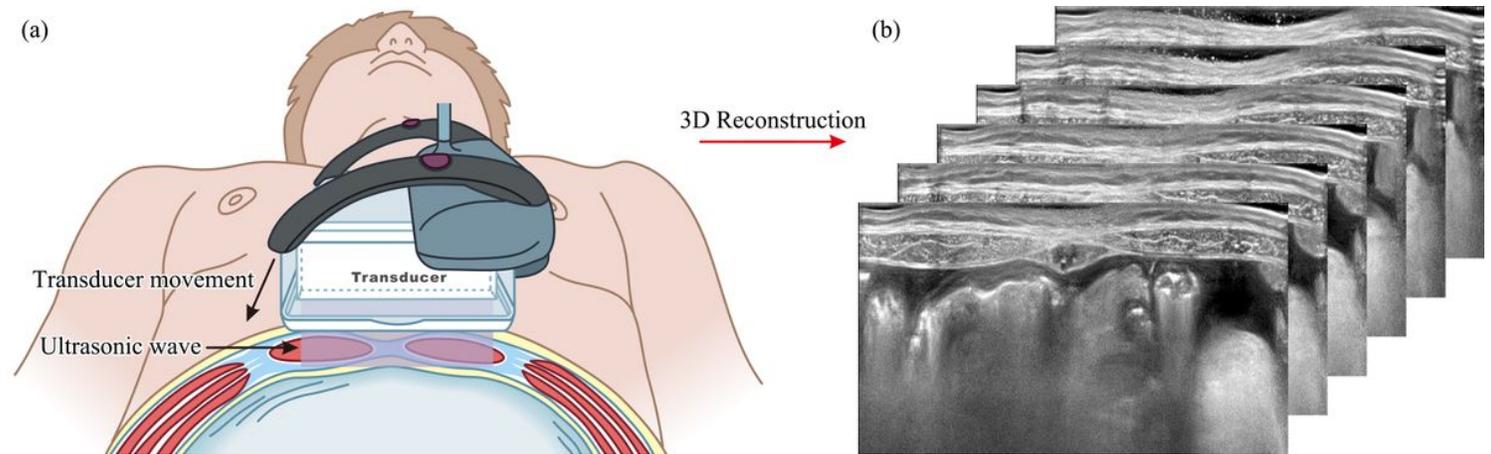

Figure 2

An illustrative example of (a) automated 3D breast ultrasound (ABUS) acquisition geometry with (b) the reconstructed tomographic anterior abdominal wall image.

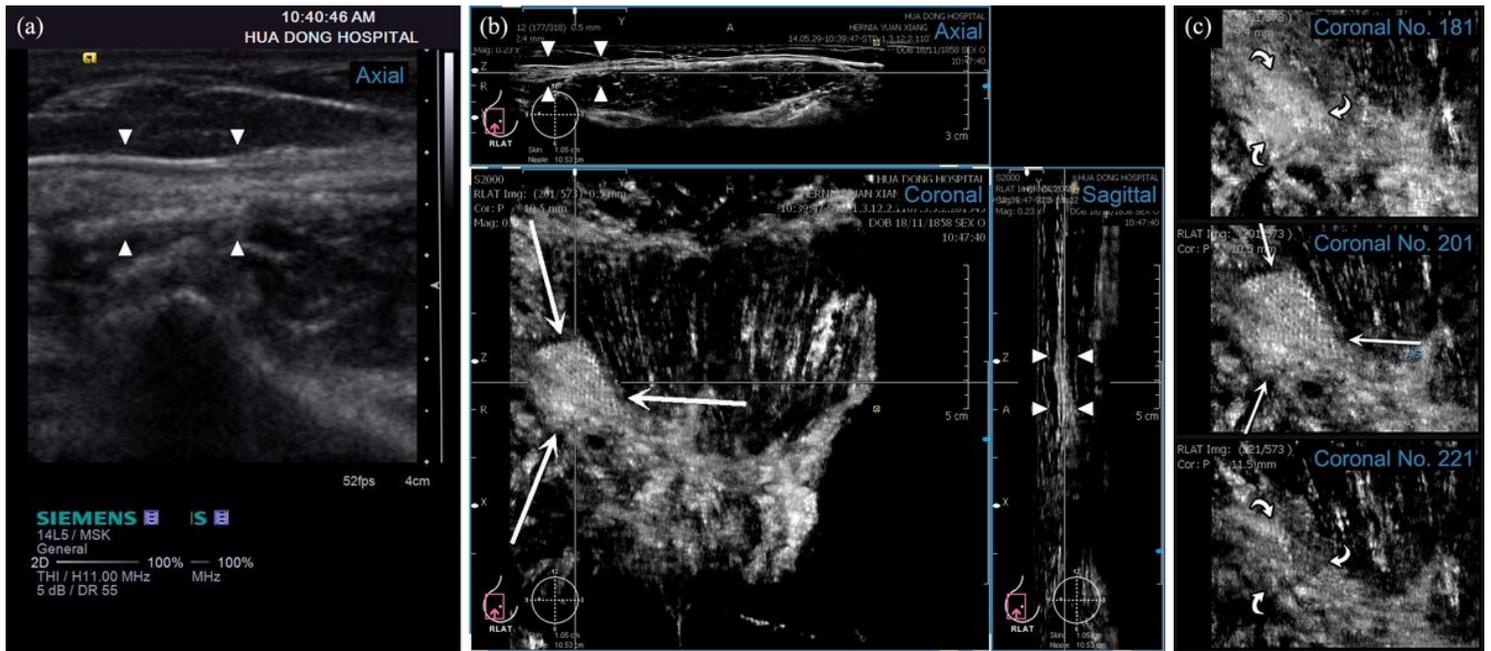

Figure 3

Differences of texture features in (a) the axial view of HHUS, (b) the three orthogonal views of ABUS and (c) coronal multislice views of ABUS for the same LW mesh. Note that the texture features of HHUS images reflect mixed properties of LW mesh overlapping fascia tissues. Therefore, it is difficult to identify the LW mesh itself separate from the fascia tissues that surround it (arrowheads). However, the new coronal plane of ABUS offers superior pore texture visualization, by separating the LW mesh (arrows) from the fascia (curved arrows) tissues.

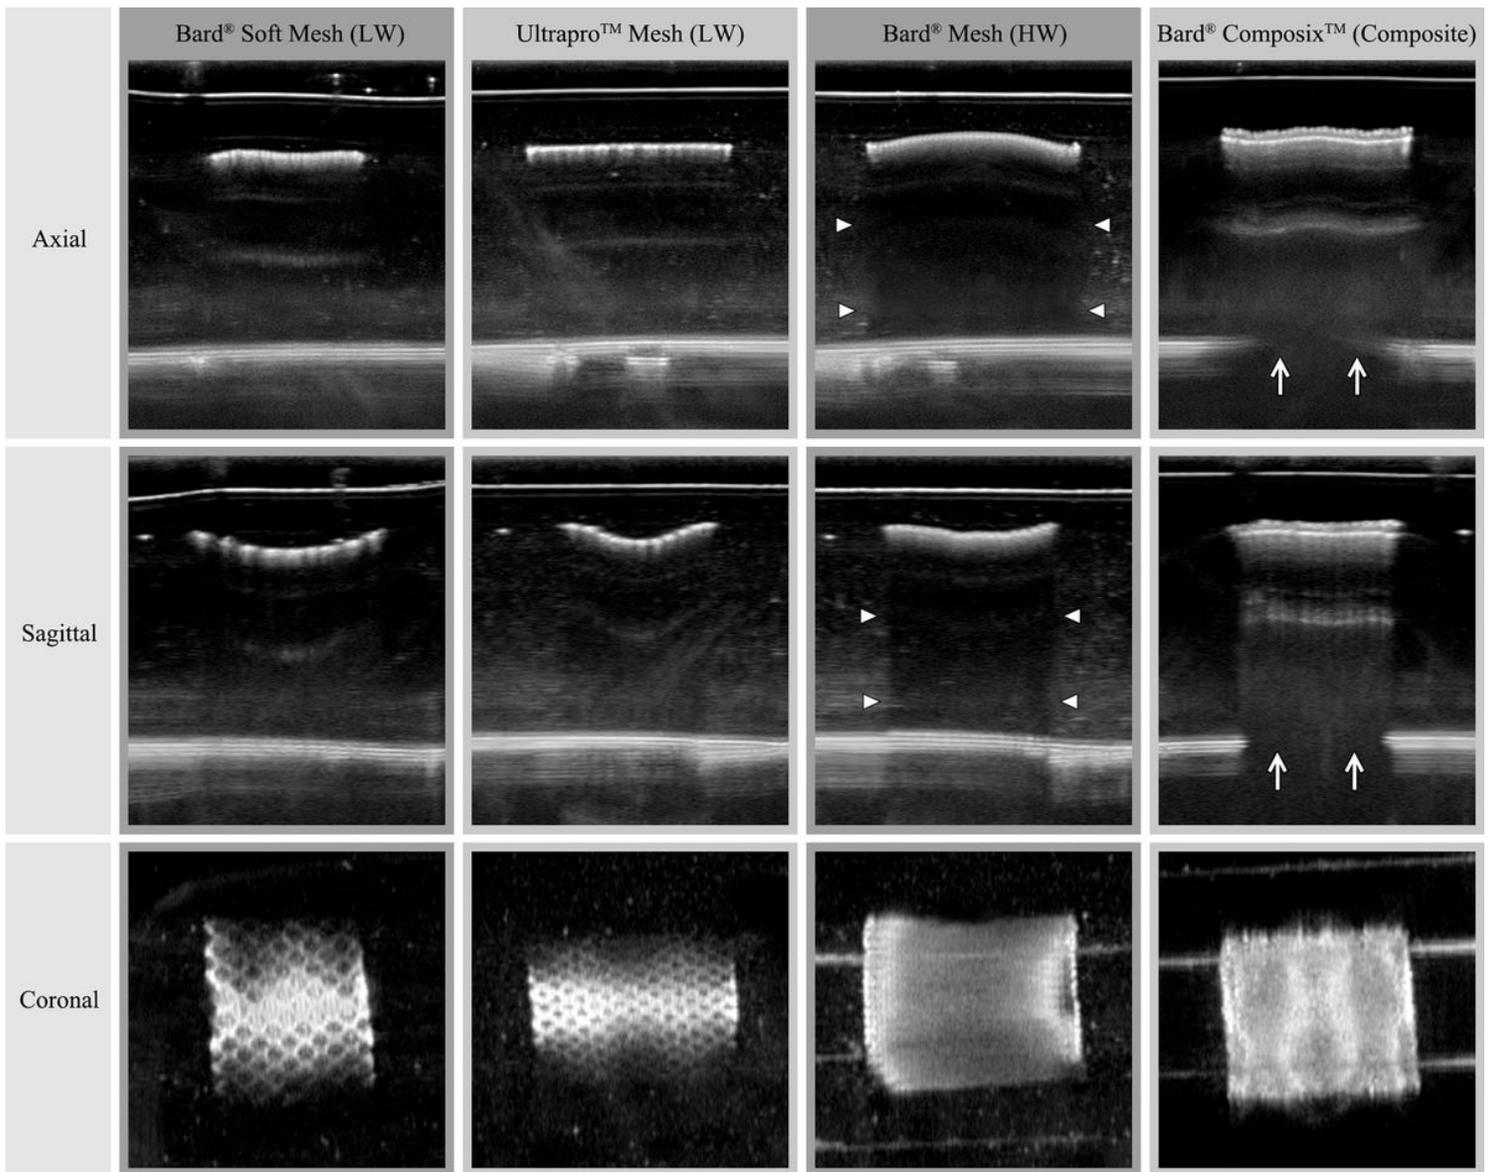

Figure 4

ABUS imaging comparisons of four tested meshes. The four columns show the Bard® Soft Mesh (LW), the Ultrapro™ Mesh (LW), the Bard® Mesh (HW), and the Bard® Composix™ Mesh (Composite) in three orthogonal views, respectively. Note that both LW Bard® Soft and LW Ultrapro™ meshes are shown in the coronal plane with distinct pore texture. The HW Bard® mesh is shown in sectional views (axial and sagittal views) with posterior acoustic shadowing (arrowheads). The Composite Bard® Composix™ mesh is shown in sectional views (axial and sagittal views) with badly posterior acoustic shadowing, and the bottom of the plastic container has been unable to observe by ultrasonography (arrows).

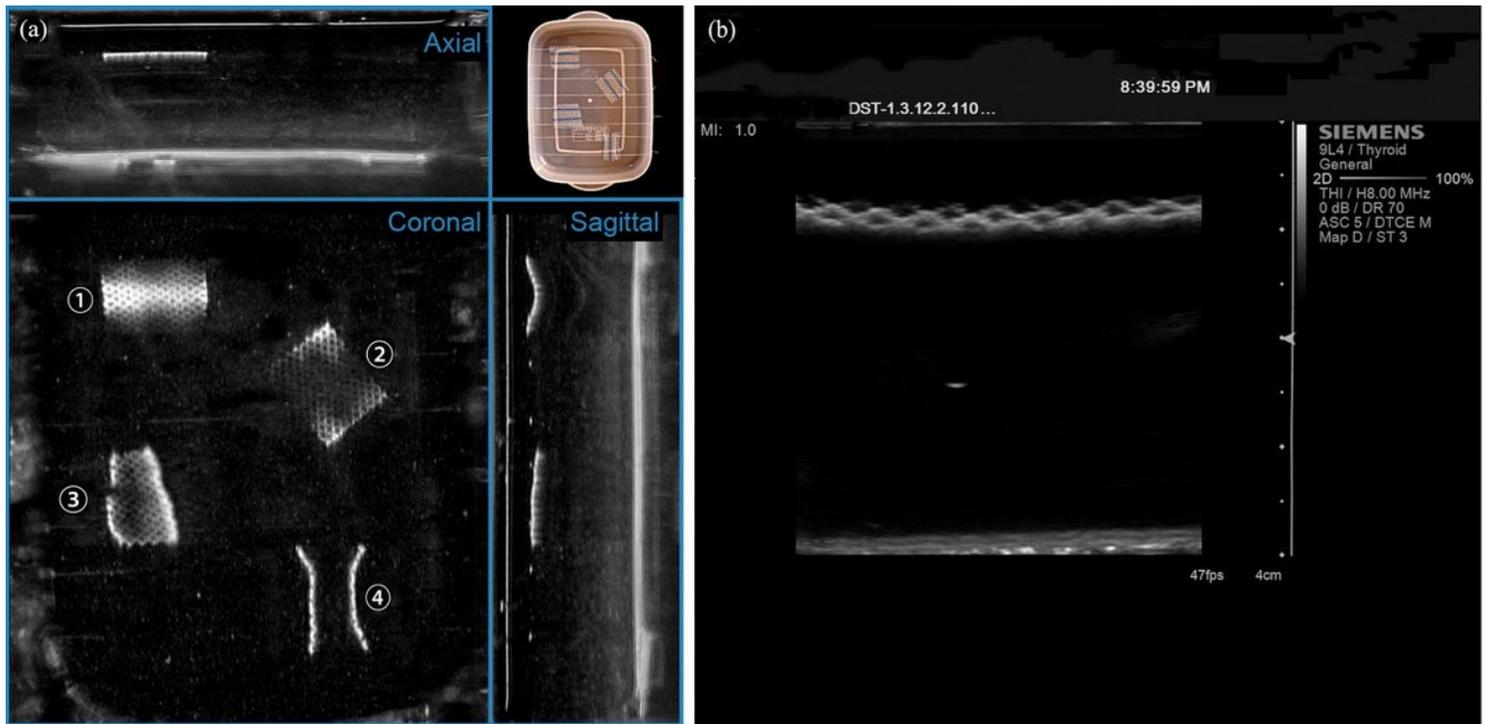

Figure 5

(a) Three orthogonal plan views of ABUS imaging of the Ultrapro™ Mesh box, while (b) is HHUS imaging result (axial plane). Note that fragment No. ① is parallel to the horizontal plane, fragment No. ② is rotated a certain angle in the horizontal plane, fragment No. ③ is rotated a certain space angle in the depth direction of the horizontal plane, and fragment No. ④ is curved to represent the shrinkage of the mesh. Note that the fragments No. ①-④ are used to simulate the mesh spatial variation that may occur after implantation.

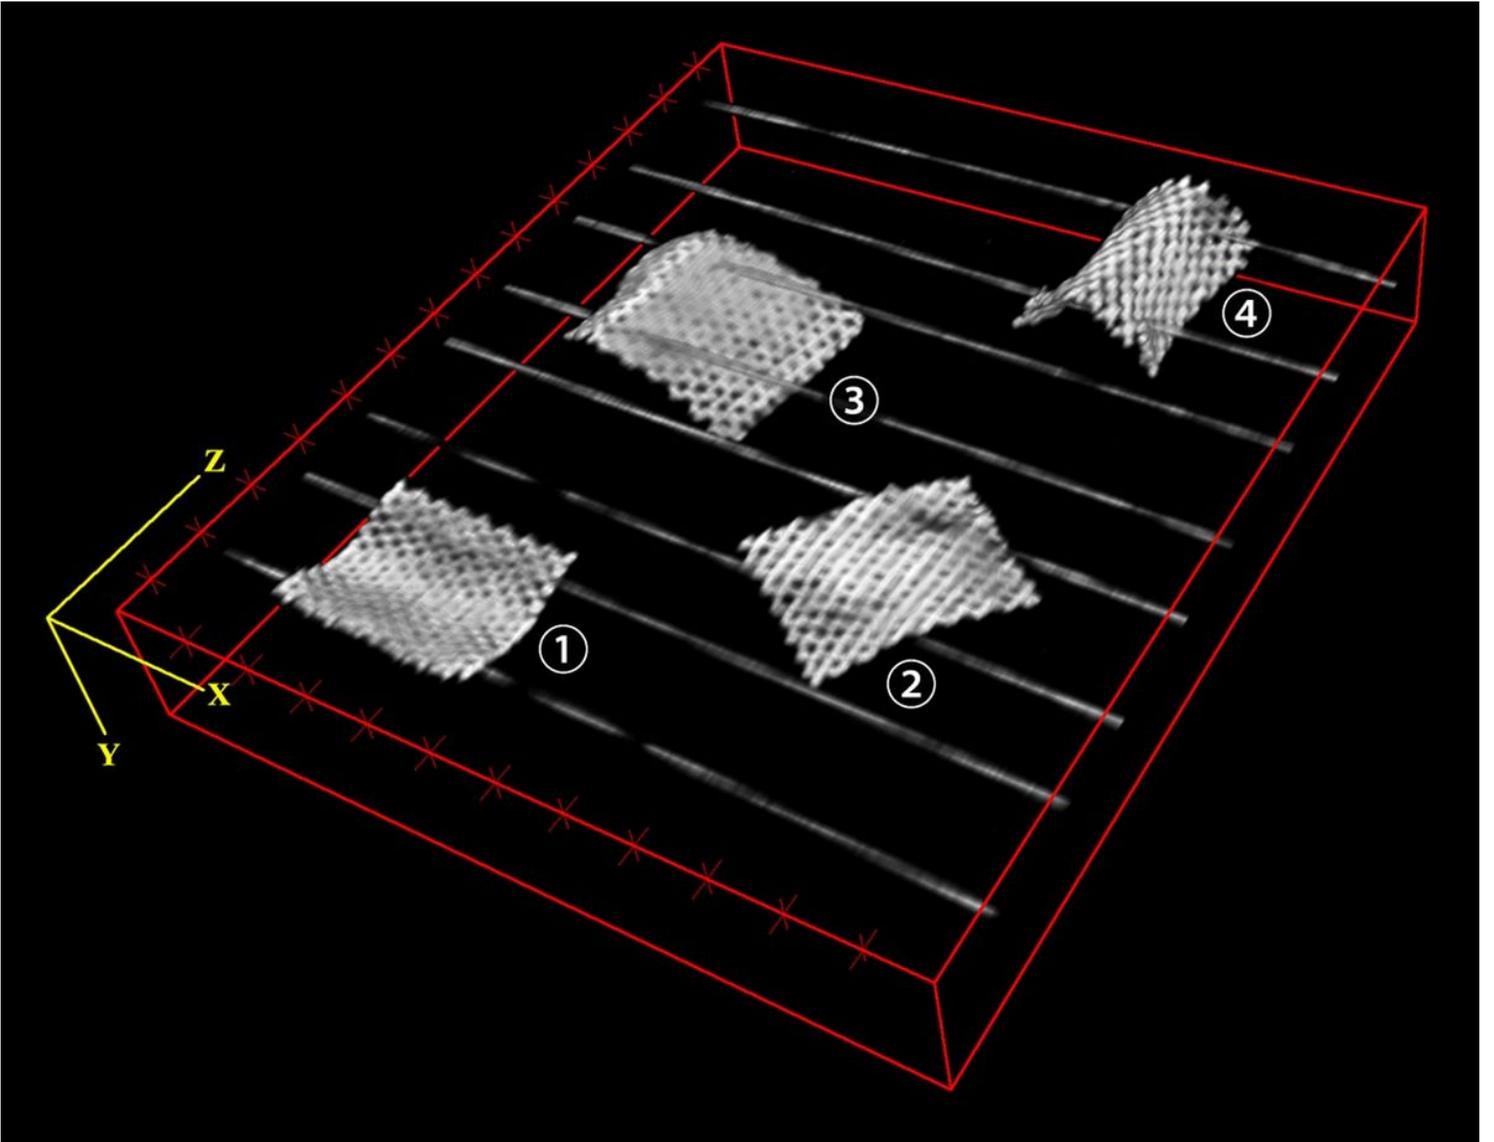

Figure 6

The 3D volume rendering results based on ABUS scan data of the Ultrapro™ Mesh box.

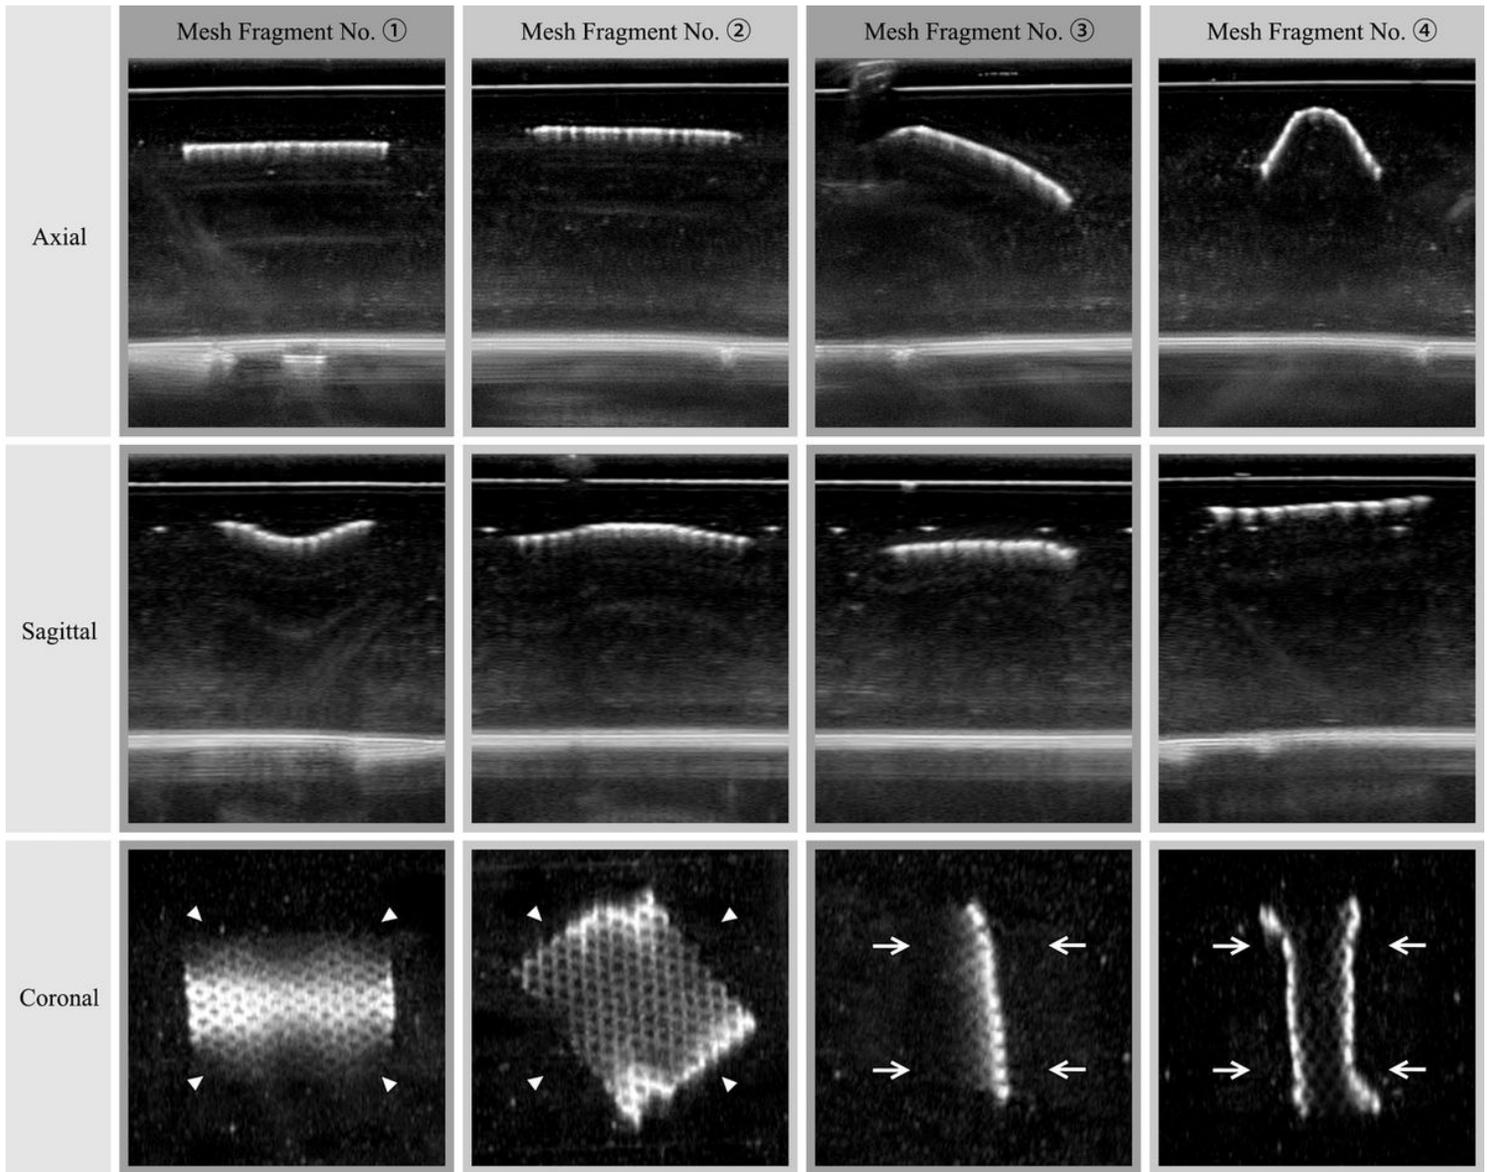

Figure 7

The results of ABUS imaging of Ultrapro™ Mesh (LW) with four mesh fragments. Note that fragment No. ① is parallel to the horizontal plane, fragment No. ② is rotated a certain angle in the horizontal plane, fragment No. ③ is rotated a certain space angle in the depth direction of the horizontal plane, and fragment No. ④ is curved to represent the shrinkage of the mesh. Note that the fragments No. ①-④ are used to simulate the mesh spatial variation that may occur after implantation.

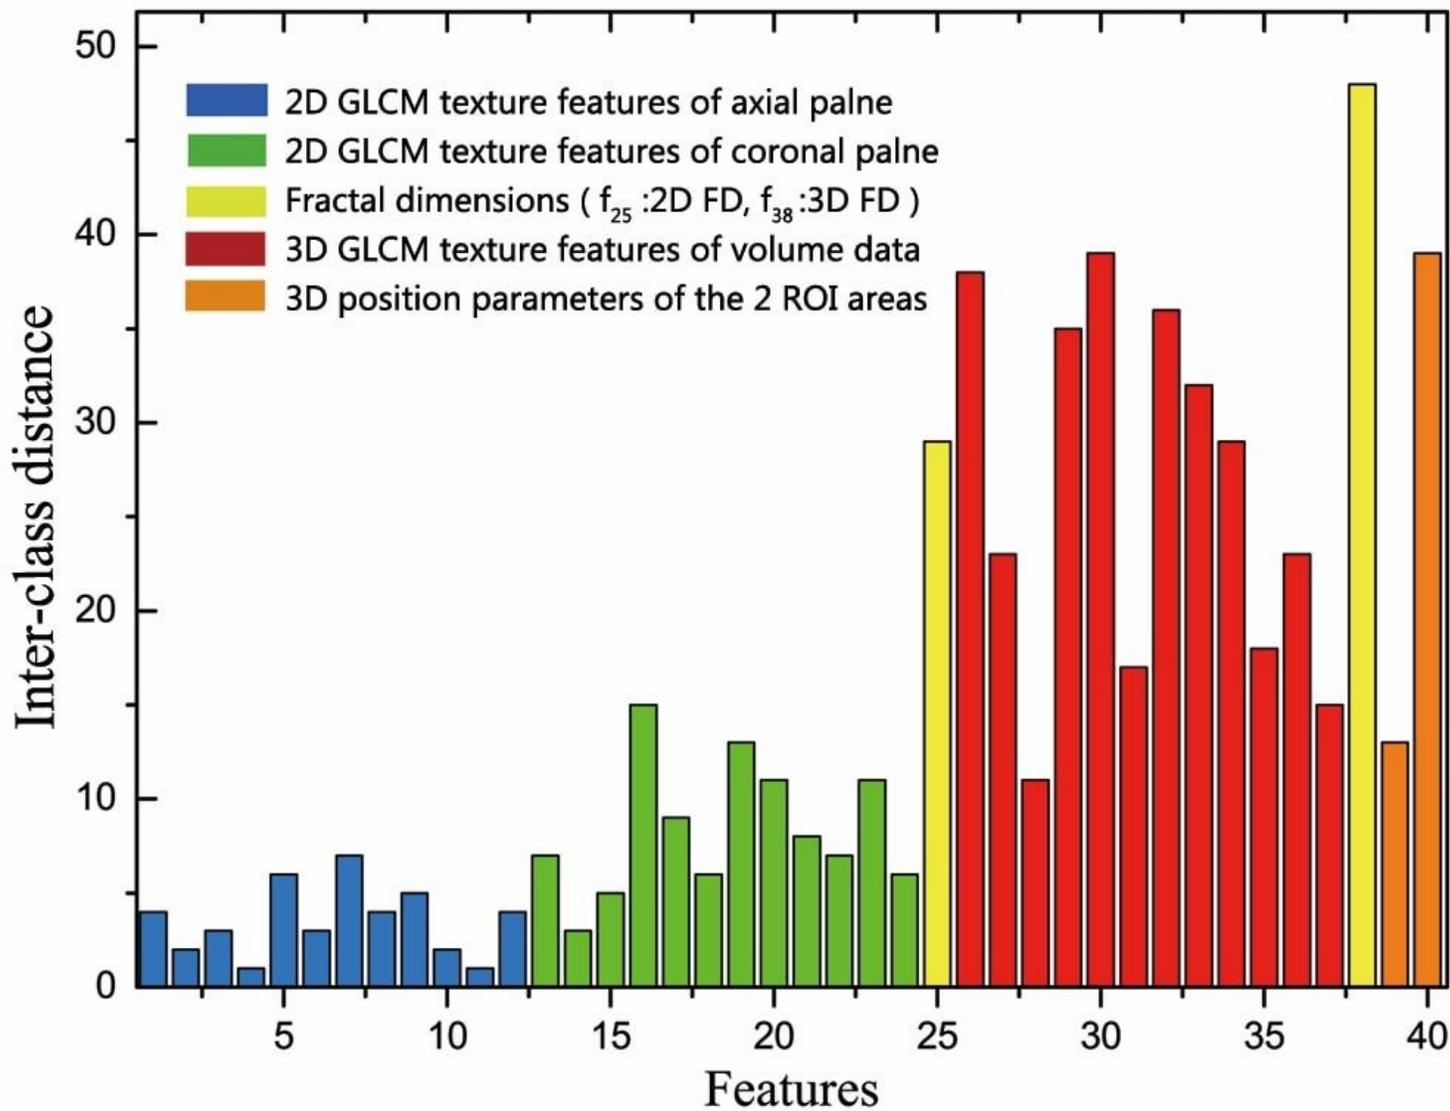

Figure 8

The inter-class distance results of all 40 pore texture features.

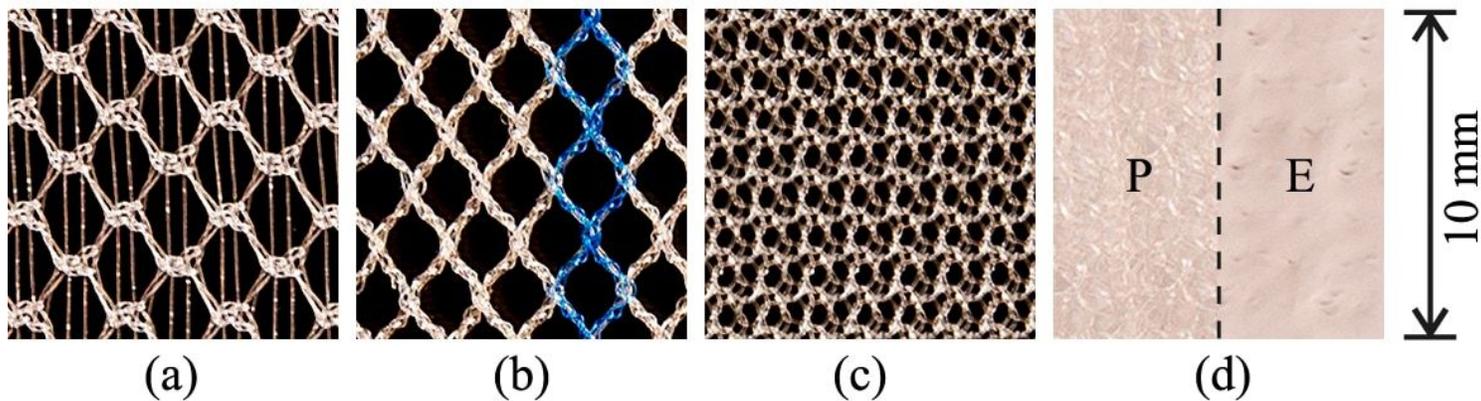

Figure 9

The top view of four tested meshes. Each photograph shows a 10 mm wide piece of the mesh material. (a) Bard® Soft Mesh (LW); (b) Ultrapro™ Mesh (LW); (c) Bard® Mesh (HW); (d) Bard® Composix™ Mesh (Composite). This composite mesh is constructed of polypropylene mesh on one side (P), bonded with expanded polytetrafluoroethylene (ePTFE) on the other (E).

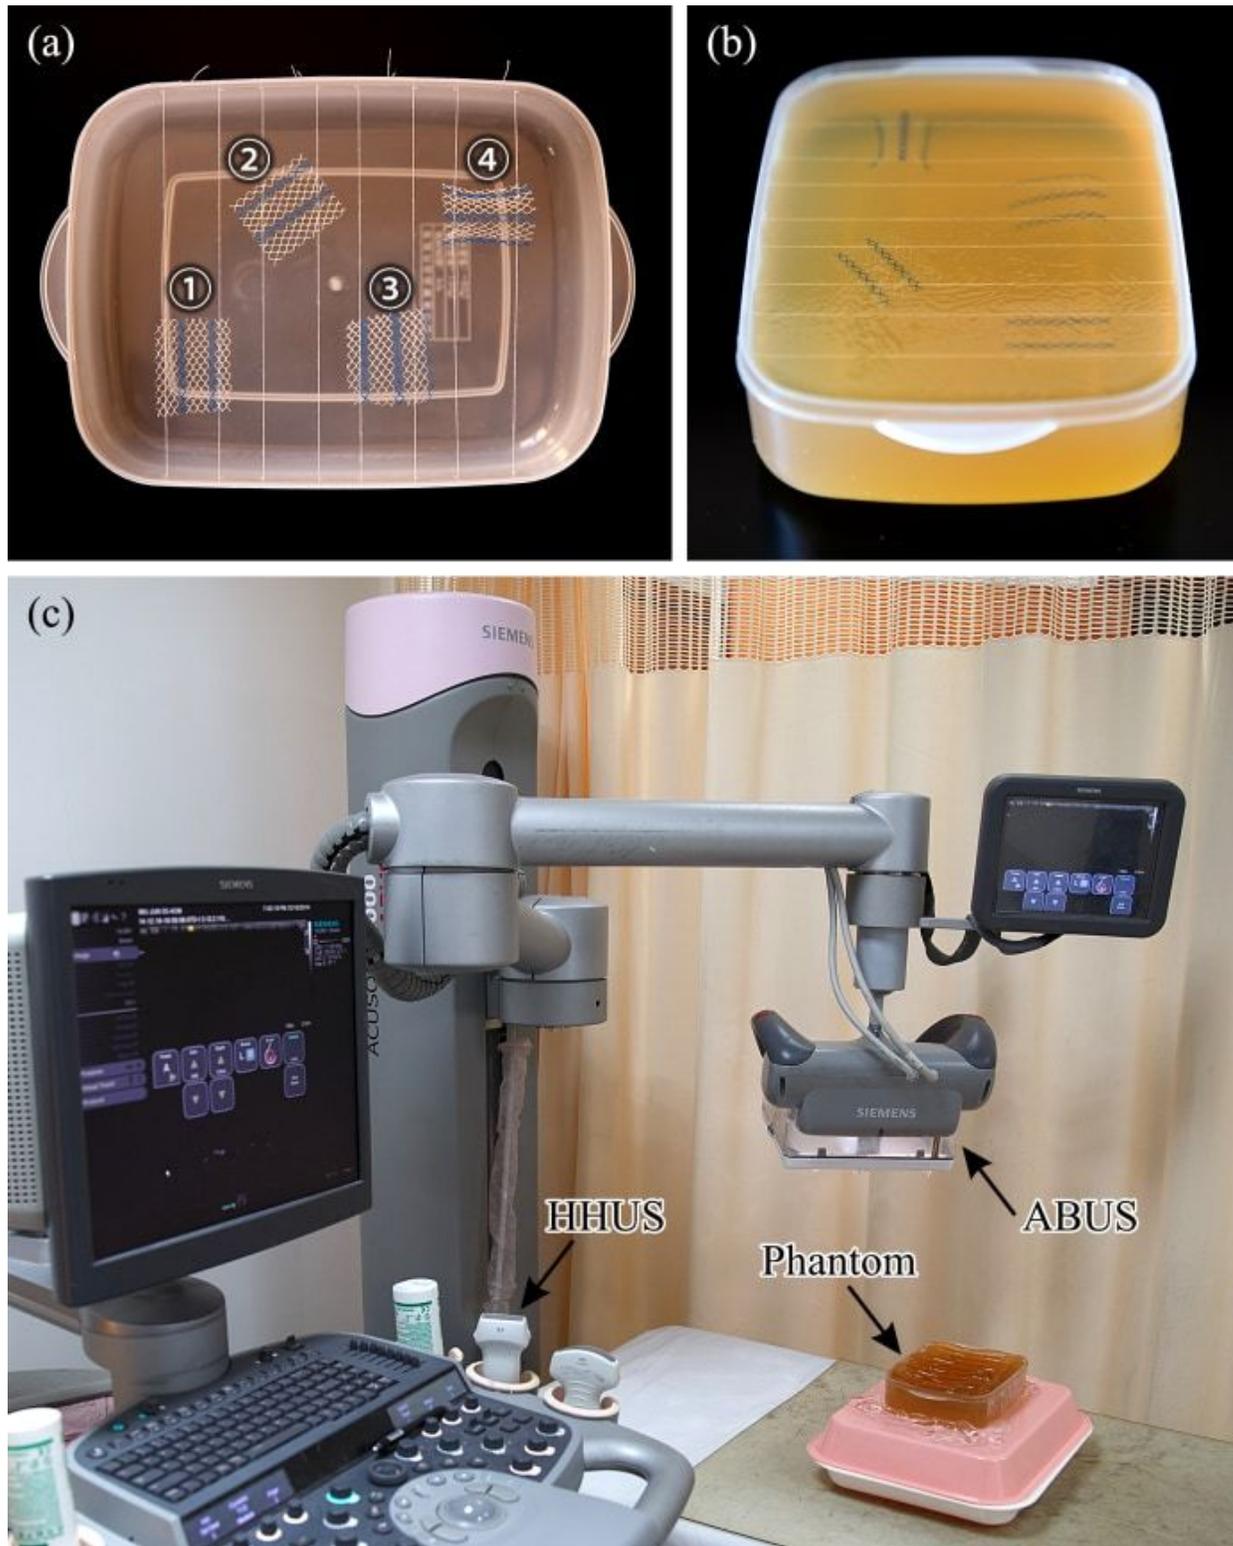

Figure 10

(a) Plastic container used to hold 4 fragments of the LW Ultrapro™ Mesh, while (b) shows the plastic container filled with gelatin. (c) The experimental equipment of in vitro study. Note that the fragments No. 1-4 are used to simulate the mesh spatial variation that may occur after implantation.

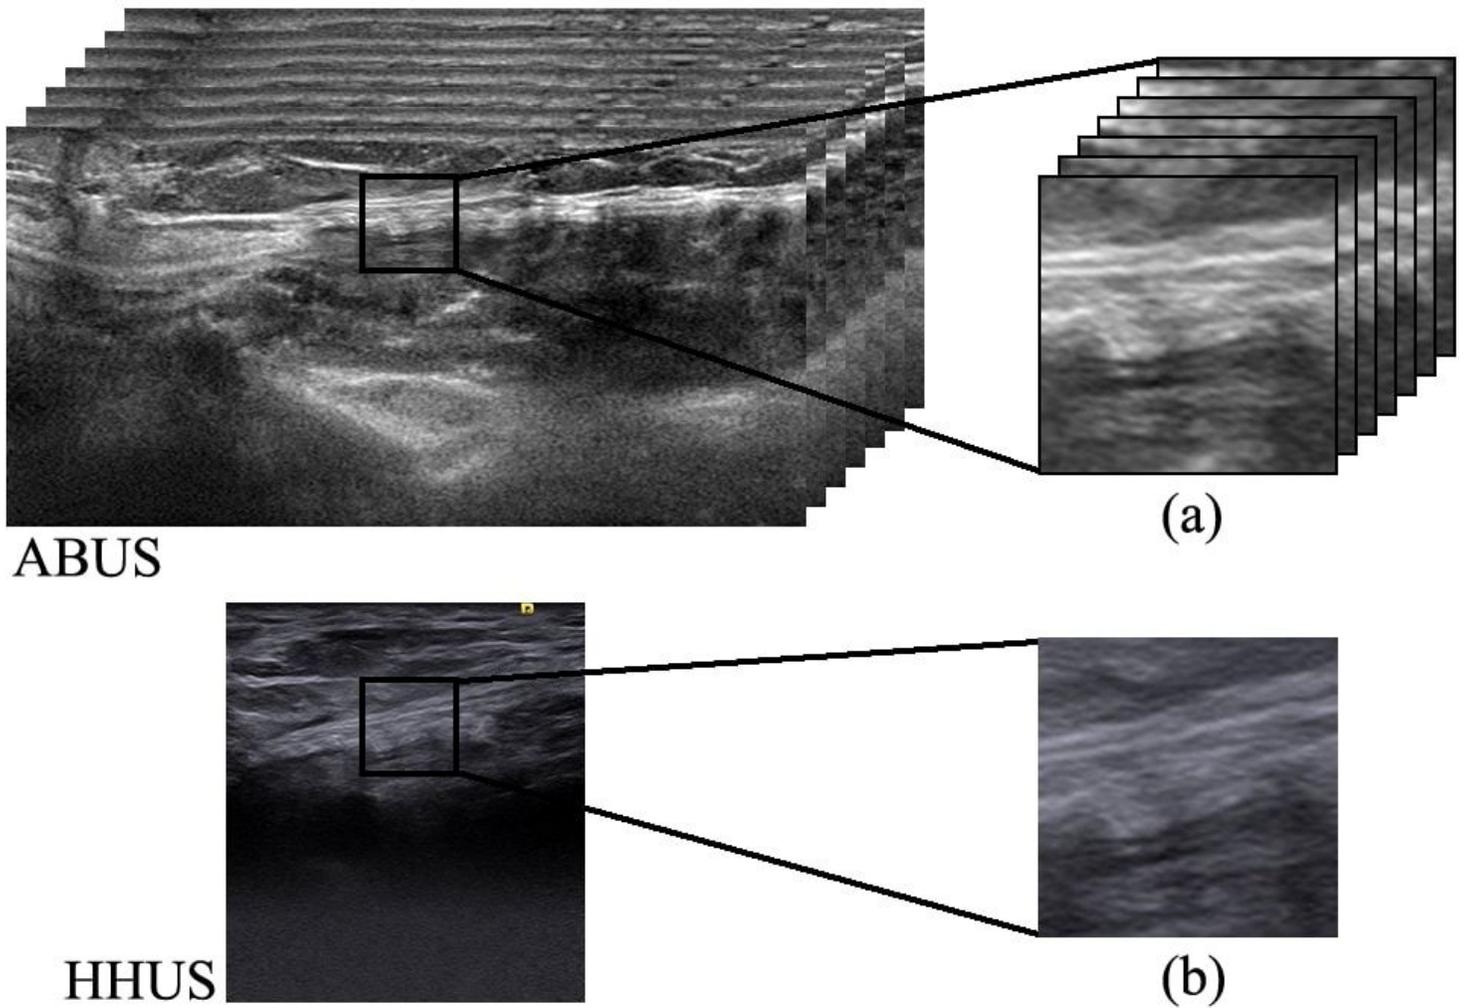

Figure 11

An illustrative example of (a) a 3D ROI segmented from a reconstructed automated 3-D breast ultrasound (ABUS) image and (b) the corresponding 2D ROI from the hand-held ultrasound (HHUS) of the same central hernia region.

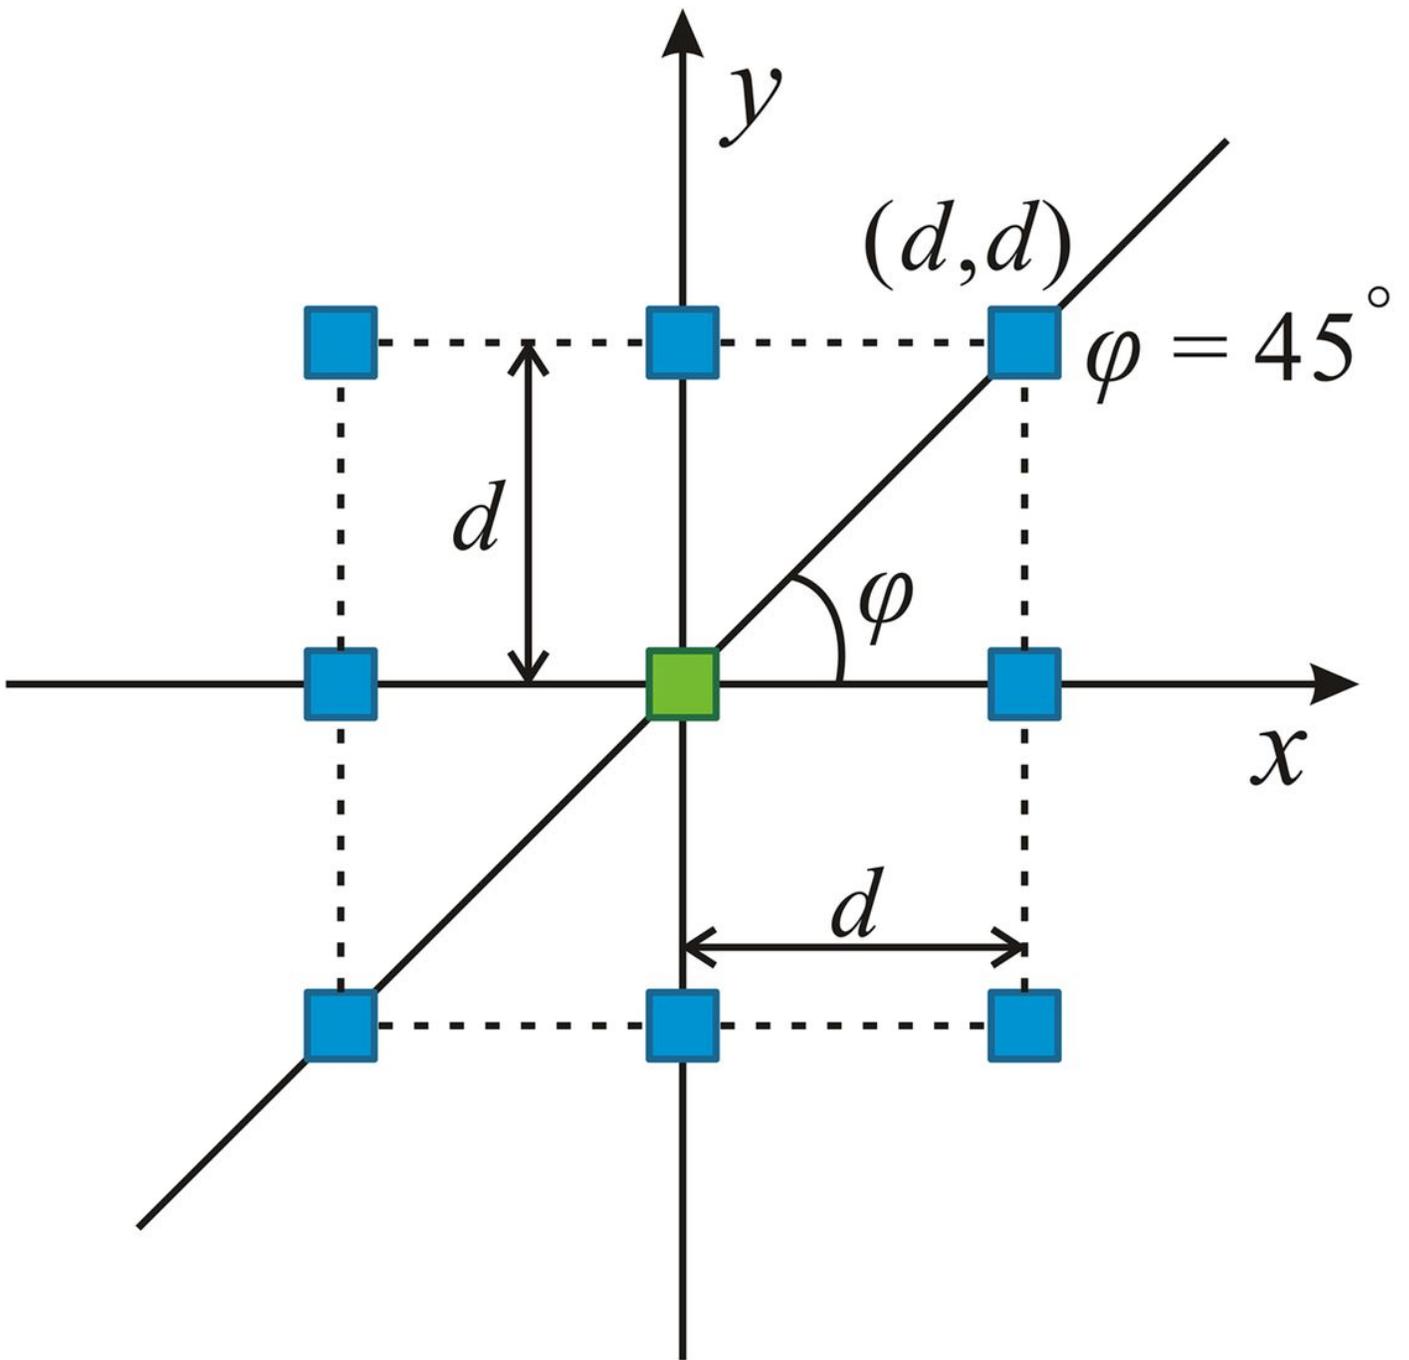

Figure 12

Spatial relations of a pair of pixels in 2D. For a particular pixel (green), it has eight neighboring pixels (blue) of norm-1 distance d in 4 independent directions.

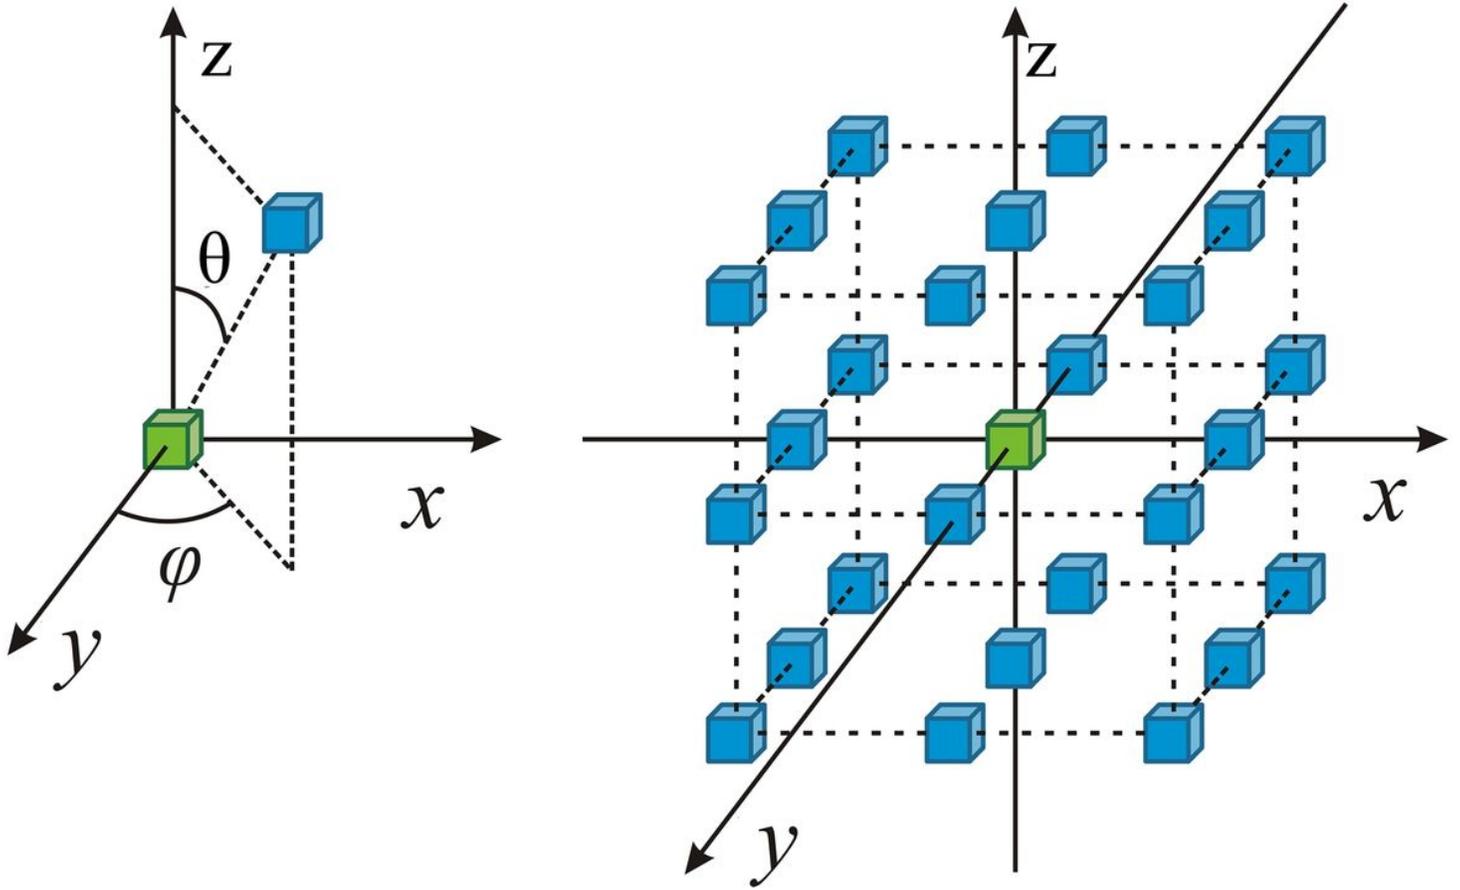

Figure 13

. Spatial relations of a pair of voxels in 3D. For a particular voxel (green), it has 26 neighbors (blue) of norm-1 distance d in 13 independent directions.
