ABSTRACT

The innate defensive behaviors triggered by environmental threats play a critical role in animal survival. Among these behaviors, defensive attack physically toward threatening target (e.g. predator) is the last line of defense to struggle for survival. How the brain transforms threat-relevant sensory information into the action of defensive attack remains poorly understood. We found that noxious mechanical force in an inescapable context was a key stimulus to trigger defensive attack in laboratory mice. The mechanically-evoked defensive attack was abrogated by photoinhibition of vGAT+ neurons in the anterior hypothalamic nucleus (AHN). The AHN vGAT+ neurons encoded the intensity of mechanical force and were innervated by brain areas related to pain and attack. Activation of these neurons triggered biting attack toward predator, while suppressing other ongoing behaviors. The efferent pathway from AHN vGAT+ neurons to the periaqueductal gray was both sufficient and necessary for mechanically-evoked defensive attack. Together, these data revealed a GABAergic brain circuit engaged in converting noxious mechanical stimuli to neural signals that provoke defensive attack in mice. (168 words)

In response to environmental threats, human and animals exhibit a cascade of innate defensive behaviors (e.g. freezing, escape, and defensive attack). These behaviors may occur as a function of physical distance of threats, as described by a classical model termed "Predatory Imminence Continuum" by Fanselow and colleagues (Fanselow and Lester, 1988). This model has been well supported by recent behavioral studies. For example, when prey detects a distant cruising predator, freezing is usually the dominant form of post-encounter defensive behavior of prey (De Franceschi et al., 2016). In response to looming visual stimuli mimicking an approaching predator, prey rapidly escapes to avoid prey capture (Yilmaz and Meister, 2013). If a cornered prey is physically attacked by predator, defensive attack of prey is often provoked as the last line of defense to struggle for survival (Blanchard and Blanchard, 1989). Relative to the well characterized brain circuits for freezing and escape (Hypothalamus: Silva et al., 2013; Wang et al., 2015; Kunwar et al., 2015; Midbrain: Wei et al., 2015; Shang et al., 2015; Tovote et al. 2016; Evans et al., 2018; Shang et al., 2018; Thalamus: Salay et al., 2018; Pons: Han et al., 2015; Review: Gross and Canteras, 2012; Branco and Redgrave, 2020), the brain mechanisms for sensory-triggered defensive attack is poorly understood. In the present study, we explored how the brain transforms threat-relevant sensory information into the action of defensive attack in mice.

Noxious mechanical stimulus to provoke defensive attack in mice

We began this study by measuring defensive attack behavior in a rodent-versus-snake paradigm (Paschoalin-Maurin et al., 2018; Mendes-Gomes et al., 2020). In an enclosed arena (10 cm x 10 cm), a male C57BL/6 mouse was exposed to a weight-matched young snake (*Elaphe schrenckii*) (Figure S1A). When the snake attacked the mouse, the mouse exhibited jumping escape and then biting-like defensive attack to the snake (Movie S1). We also observed biting-like defensive attack in rat (Figure S1B, Movie S2) and hamster (Figure S1C, Movie S3) when they were physically

3

attacked by the snake. These observations indicated that rodents exhibit robust anti-predator defensive attack behavior in laboratory conditions.

To identify the key stimulus to provoke defensive attack, we performed three experiments using mouse as an animal model. First, we examined the defensive responses of mice to a plastic dummy snake, which was either coated with snake feces to provide predator-derived olfactory cues or equipped with an alligator-clip to apply noxious mechanical stimuli (Figure 1A). Predator-derived olfactory cues on the dummy snake did not provoke defensive attack (Movie S4; Figure 1B, 1C & 1E) but promoted freezing, risk assessment and avoidance in mice (Figure S2, A-C). When the alligator-clip on the dummy snake applied sustained mechanical force (366 grams) by clamping the tail of mice，they exhibited biting attacks toward the dummy snake (Movie S5; Figure 1D & 1F) without showing freezing, risk assessment or avoidance (Figure S2, D-F). The defensive attack provoked by the alligator-clip clamping on the tail was similarly observed in the light (~50 lux) and dark (~0.002 lux) conditions, suggesting visual detection of the alligator clip clamping the tail may play a minor role in provoking such defensive attack (Figure S2, G-I). The noxious mechanical stimuli applied on the limbs of mice also induced robust biting attack toward dummy snake (Figure S2J). Second, we found that the mice also exhibited biting-like attacks to neutral objects when these objects were physically connected to noxious mechanical stimulus (Movie S6; plastic lid: Figure S3A; wood block: Figure S3B). These data again underscored the role of noxious mechanical force as a general stimulus to trigger defensive attack. Third, we performed genetic ablation of Mrgprd+ sensory neurons, which may mediate behavioral responses to noxious mechanical stimuli (Cavanaugh et al., 2009), by expressing diphtheria toxin receptor (DTR) in Mrgprd+ neurons. In the Mrgprd-CreERT2/iDTR/Ai3 mice (Olson et al., 2017; Buch et al., 2005; Madisen et al., 2010), tamoxifen injections and subsequent diphtheria toxin injections decreased (86% ± 7%, n= 7 pairs) the number of EYFP+ neurons (putatively Mrgprd+) in the dorsal root ganglion (Figure 1G).

94   This genetic manipulation significantly reduced biting attack in mice with the tail or limb

95   clamped by the alligator-clip (Figure 1H and 1I). Together, these three lines of evidence

96   suggested that noxious mechanical force may be a key stimulus to evoke defensive

97   attack in mice.

98   **AHN vGAT+ neurons are required for mechanically-evoked defensive attack**

99   Then we explored the brain circuits for mechanically-evoked defensive attack.

100   Earlier studies reported that the medial hypothalamic zone (MHZ) plays a critical role in

101   the expression of defensive behaviors, especially with respect to predators (Canteras et

102   al., 1997; Canteras et al., 2002). The MHZ includes the anterior hypothalamic nucleus

103   (AHN), dorsomedial part of ventromedial hypothalamic nucleus (VMHdm) and dorsal

104   premammillary nucleus (PMd). Neurons in the VMHdm and PMd participate in defensive

105   behaviors such as freezing and escape (Silva et al., 2013; Wang et al., 2015; Kunwar et

106   al., 2015; Cezario et al., 2008). The AHN may participate in intraspecific aggression (Rat:

107   Olivier et al., 1983; Cat: Fuchs et al., 1985; Hamster: Delville et al., 2000; Prairie Voles:

108   Gobrogge et al., 2007; Finch: Goodson et al., 2012). However, the role of AHN in

109   anti-predator defensive behavior remains unknown. A recent study demonstrated that

110   the rats threatened by snakes showed robust increase in c-Fos expression in the AHN

111   (Paschoalin-Maurin et al., 2018), prompting us to test the hypothesis that AHN neurons

112   may be involved in mechanically-evoked defensive attack in mice.

113   Fluorescent in situ hybridization analyses (Figure S4A-S4C) indicated that the AHN

114   neurons are predominantly vGAT+ (92% ± 3.6%, n=3 mice), with only a small proportion

115   are vGlut2+ (8% ± 0.7%, n=3 mice). To explore the contributions of vGAT+ and vGlut2+

116   AHN neurons to mechanically-evoked defensive attack, we employed vGAT-IRES-Cre

117   and vGlut2-IRES-Cre mice to genetically manipulate these AHN neurons (Vong et al.,

118   2011). The specificity and efficiency of these Cre lines to label vGAT+ and vGlut2+ AHN

119   neurons were confirmed in control experiments (Figure S4D-S4O). We injected

120   AAV-DIO-GtACR1-2A-EGFP (Govorunova et al., 2015) into the AHN of vGAT-IRES-Cre

121 and vGlut2-IRES-Cre mice, followed by optical fiber implantation above the AHN

122 bilaterally (Figure 2A; Figure S5A and S5B). The cell-type specificity of

123 GtACR1-2A-EGFP expression was confirmed in control experiments (Figure S5C-S5F).

124 The effect of photoinhibition on AHN neurons expressing GtACR1 was validated in acute

125 brain slices (Figure 2B). By recording electromyogram (EMG) from masseter muscles in

126 freely moving mice (Falkner et al., 2020) (Figure 2C), we were able to measure the

127 initiation and termination of biting bouts during defensive attack (Figure S5G). We found

128 that photoinhibition of AHN vGAT+ neurons (473 nm, 2s-OFF/2s-ON, 10 mW) rapidly

129 (latency = 0.82 s ± 0.12 s; n=7 mice) terminated biting attack provoked by noxious

130 mechanical stimuli (Movie S7; Figure 2D-2F). In contrast, photoinhibition of AHN vGlut2+

131 neurons did not prevent mechanically-evoked defensive attack (Figure 2G-2I). As a

132 control experiment, photoinhibition of AHN vGAT+ neurons did not alter average

133 locomotion speed of freely-moving mice (Figure S5H). These data suggested that the

134 AHN vGAT+ neurons are selectively required for mechanically-evoked defensive attack

135 in mice.

136 **AHN vGAT+ neurons encode mechanical stimuli**

137 To test whether AHN vGAT+ neurons respond to noxious mechanical stimuli, we

138 expressed jGCaMP7s in these neurons and recorded GCaMP fluorescence with fiber

139 photometry (Gunaydin et al., 2014; Dana et al., 2019) (Figure 3A; Figure S6A and S6B).

140 In head-fixed mice standing on a treadmill, noxious mechanical stimulus applied by the

141 alligator-clip to mouse tail robustly increased the GCaMP fluorescence (Figure 3B).

142 However, in other behavioral tests (biting attack, locomotion, risk assessment, object

143 exploration and social investigations), the GCaMP fluorescence was only modestly

144 increased (Figure S6C-S6H; Figure 3C). These data suggested that AHN vGAT+

145 neurons may preferentially respond to noxious mechanical stimuli.

146 To test whether single AHN vGAT+ neurons encode mechanical stimuli, we

147 expressed ChR2-mCherry in these neurons and performed single-unit recording with an

optrode in the AHN of head-fixed awake mice (Figure 3D; Figure S7A). The putative

vGAT+ AHN neurons were identified according to the action potentials (APs) evoked by

light pulses (473 nm, 1 ms, 10 mW) illuminating on ChR2-mCherry[+] AHN neurons. The

light-evoked APs had to conform to two criteria: first, their latencies to the light pulses

should be less than 5 ms; second, their waveforms should be similar to those of

sensory-evoked APs (Cohen et al., 2012). With these empirical criteria, we identified 15

units as putative AHN vGAT+ neurons. Their light-evoked APs had short response

latencies (2.7 ms ± 0.4 ms, n=15 units; Figure 3E) and possessed waveforms

quantitatively correlated with those of mechanically-evoked APs (Figure S7B; Figure 3F).

Then we examined the responses of these 15 putative AHN vGAT+ neurons to

mechanical and olfactory stimuli. Mechanical stimuli were applied by an alligator-clip

clamping on mouse tail (Figure S7C and S7D). Snake feces coated on a cotton swab

was used to provide olfactory stimuli of predator (Figure S7E and S7F). The 15 putative

AHN vGAT+ neurons responded to both mechanical stimuli and olfactory stimuli (Figure

3G). However, the responses to mechanical stimuli were significantly stronger than those

to olfactory stimuli of predator (Figure 3H; One-Way ANOVA, P<0.001). These data

confirmed the GCaMP results that vGAT+ AHN neurons preferentially respond to

mechanical stimuli.

To quantitatively test how AHN vGAT+ neurons encode mechanical force, we used

von Frey filaments (1g, 10g, and 100g) to poke different body parts of mice (Figure S7G).

The 15 putative AHN vGAT+ neurons responded to von Frey filaments poking on the tail

in a graded manner (Figure 3I and S7H) and preferred stronger mechanical force (1g vs.

10g: P<0.001; 10g vs. 100g: P<0.001; n=15 units, One-Way ANOVA; Figure 3J).

Moreover, these neurons also responded to mechanical stimuli delivered to four limbs,

with a bias toward the contralateral side (Figure 3K). They exhibited clear adaptation in

response to repetitive mechanical stimuli at 0.5 Hz (Figure 3L). Recording sites marked

174   by electrolytic lesion were all located within the AHN (Figure S7I). Together, these data

175   suggested that AHN vGAT+ neurons encode mechanical stimuli on the body surface.

176   Mapping monosynaptic inputs of AHN vGAT+ neurons

177   With recombinant rabies virus (RV), we next performed monosynaptic retrograde

178   tracing (Wickersham et al., 2007) to examine how AHN vGAT+ neurons are connected

179   with brain areas associated with mechanical stimuli or attack behavior (Figure S8A-S8C).

180   A brain-wide survey revealed a number of monosynaptic projections to the AHN vGAT+

181   neurons (Figure S8D and S8E). First, robust monosynaptic inputs arise from the lateral

182   parabrachial nucleus (LPB) and paraventricular thalamic nucleus (PVT) (Figure S8, D1

183   and D2), two brain areas that were directly innervated by TAC1+ spinal neurons for

184   pain-related defensive behaviors (Huang et al., 2019). Second, AHN vGAT+ neurons are

185   monosynaptically innervated by neurons in the VMH and lateral septal nucleus (LS)

186   (Figure S8, D3 and D4), both of which have been related to attack behaviors in mice

187   (VMH: Lin et al., 2011; LS: Leroy et al., 2018). Third, consistent with the observation that

188   AHN vGAT+ neurons modestly responded to predator-derived olfactory cues, we found

189   that these neurons receive sparse innervations from the medial amygdala (MA) (Figure

190   S8, D3), which convey olfactory signals from the accessory olfactory bulb to

191   hypothalamic nuclei (Isogai et al., 2011). These data supported the hypothesis that AHN

192   vGAT+ neurons are within a brain network for mechanically-evoked defensive attack.

193   AHN vGAT+ neurons trigger biting attacks toward non-social targets

194   Then we tested whether activation of AHN vGAT+ neurons is sufficient to trigger

195   defensive attack behavior. We injected AAV-DIO-ChR2-mCherry into the AHN of

196   vGAT-IRES-Cre mice, followed by implantation of optical fibers above the AHN (Figure

197   4A). The cell-type specificity of ChR2-mCherry expression in AHN vGAT+ neurons was

198   confirmed in control experiments (Figure 4B and S9A). The effectiveness of

199   photostimulation to trigger action potential firing in ChR2-mCherry+ AHN neurons was

validated in acute brain slices (Figure 4C). When the test mice were confronted with a live snake in the arena (Figure 4D), the mice exhibited a series of defensive responses (risk assessment, avoidance, and freezing); light-stimulation of AHN vGAT+ neurons rapidly switched mouse behavior to biting-like attack toward the snake (Movie S8; Figure 4E). Quantitative measurement of time spent on these behaviors indicated that light-stimulation rapidly evoked biting-like attack toward the snake (latency = 2.7 s ± 0.4 s, n= 7 mice; Figure 4F) and suppressed other defensive behaviors (Risk assessment: Figure 4G; Avoidance: Figure S9B; Freezing: Figure S9C). Light-evoked biting attack was a function of the frequency and laser power of light stimulation (Figure S9D and S9E). The biting actions toward snake in the attack episodes were confirmed by EMG recording (Movie S9; Figure S9F and S9G). The same photostimulation also evoked biting-like attack to the wood block (Movie S10; Figure S9H-S9K), which was reminiscent of the earlier observation that neutral targets linked to noxious mechanical stimuli also evoked defensive attack (Figure S3).

One important concern about the specificity of biting-like attack evoked by AHN vGAT+ neurons may be raised. Activation of AHN vGAT+ neurons may broadly provoke an aggressive state that drives the mice to attack any targets without target-specificity. To address this concern, we examined how light-stimulation of AHN vGAT+ neurons affects social aggression. Unexpectedly, when the test mouse in its homecage exhibited social aggression to a male intruder (Figure 4H), light-stimulation of AHN vGAT+ neurons strongly suppressed ongoing social attack (Movie S11; Figure 4I and 4J). In addition, in male mice without showing social aggression, light-stimulation of AHN vGAT+ neurons did not evoke social attack to male or female conspecifics (Male: Movie S12; Figure S10A-S10D; Female: Movie S13; Figure S10F-S10I). These results suggested that activation of AHN vGAT+ neurons induced biting-like attack selectively to non-social targets.

226   Although light-stimulation of AHN vGAT+ neurons did not evoke social attack, it

227   increased the time for social investigation to conspecifics (Figure 4K, S10E and S10J).

228   To measure the priority level of light-evoked biting attack to predator and social

229   investigation to conspecifics, we performed two additional experiments. First, in an arena

230   with both snake and male conspecifics (Figure 4L), the test mice actively investigated the

231   male conspecifics before light-stimulation; light-stimulation of AHN vGAT+ neurons

232   rapidly switched mouse behavior from social investigation to biting-like attack toward the

233   snake (Movie S14; Figure 4M-4O; Figure S11A-S11D). Second, in the presence of both

234   snake and female conspecifics in the arena (Figure 4P), the test mice spent considerable

235   time in typical courtship behaviors toward the female before light-stimulation;

236   light-stimulation of AHN vGAT+ neurons rapidly switched mouse behavior to biting-like

237   attack toward predator (Movie S15; Figure 4Q-4S; Figure S11E-S11H). Thus, the

238   anti-predator defensive attack evoked by light-stimulation of AHN vGAT+ neurons has a

239   higher priority than social investigation.

240   **The vGAT+ AHN-PAG pathway for mechanically-evoked defensive attack**

241   Then we explored the efferent pathways of AHN vGAT+ neurons involved in

242   defensive attack, by injecting AAV-DIO-EGFP-Syb2 into the AHN of vGAT-IRES-Cre

243   mice (Figure S12A and S12B). Consistent with an earlier study (Risold et al., 1994), we

244   found that the AHN vGAT+ neurons divergently projected to different brain regions

245   ipsilaterally, including MPOA, LS, VMH, PMd, vlPAG, and other areas (Figure

246   S12C-S12G). Both the vlPAG and LS have been implicated in attack-related behaviors in

247   mice (vlPAG: Park et al., 2018; Falkner et al., 2020; LS: Leroy et al., 2018). Thus, we

248   tested whether activation of vGAT+ AHN-vlPAG or AHN-LS pathway would evoke

249   defensive attack behavior. AAV-DIO-ChR2-mCherry was injected into the AHN of

250   vGAT-IRES-Cre mice, followed by optical fibers implanted above ChR2-mCherry+ axon

251   terminals in the vlPAG (Figure 5A; Figure S13A and S13B). Light stimulation of vGAT+

252   AHN-vlPAG pathway reliably provoked biting-like attack toward live snake (Figure 5B

and 5C) and suppressed other defensive behaviors (Figure S13C-S13E). In contrast, activation of vGAT+ AHN-LS pathway failed to induce biting-like attack toward snake (Figure S14A-S14H). These data suggested that vGAT+ AHN-vlPAG pathway may be the primary pathway to provoke anti-predator defensive attack in mice.

To rule out the possibility of collateral activation, we examined whether the anti-predator attack behavior triggered by AHN vGAT+ neurons could be blocked by the antagonist of GABAa receptor (picrotoxin, PTX) infused in the vlPAG. AAV-DIO-ChR2-mCherry was injected into the AHN of vGAT-IRES-Cre mice, followed by implanting an optical fiber above the AHN and cannulae above the vlPAG (Figure 5D; Figure S15A and S15B). In acute brain slices, perfusion of PTX effectively abrogated light-evoked GABAergic postsynaptic currents in vlPAG neurons (Figure S15C; Figure 5E and 5F). In behaving mice, delivery of PTX (100 μM) through cannulae (Figure S15D) blocked the light-evoked anti-predator attack in a dose-dependent manner (Figure S15E and S15F; Figure 5G). As a control, delivery of saline did not alter light-evoked anti-predator attack (Figure 5H).

To determine whether vGAT+ AHN-vlPAG pathway is required for mechanically-evoked defensive attack, we injected AAV-DIO-GtACR1-2A-EGFP in the AHN of vGAT-IRES-Cre mice, followed by optical fiber implantation above the vlPAG (Figure 5I; Figure S16A and S16B). Photoinhibition of vGAT+ AHN-vlPAG pathway significantly impaired mechanically-evoked defensive attack behavior (Figure S16C; Figure 5J and 5K). In control experiment, light illumination on EGFP-expressing axon terminals of AHN vGAT+ neurons in the vlPAG did not change mechanically-evoked defensive attack (Figure S16C; Figure 5J and 5K). These results suggested that the vGAT+ AHN-vlPAG pathway is required for mechanically-evoked defensive attack in mice.

DISCUSSION

In response to environmental threats, human and animals exhibit a cascade of innate defensive behaviors (e.g. freezing, escape, and defensive attack). Relative to the well characterized neural circuits for freezing and escape, the brain mechanisms underlying defensive attack are poorly understood. In the present study, we explored how the brain transforms threat-relevant sensory information into the action of defensive attack in mice.

Noxious mechanical stimuli to provoke defensive attack

By using a dummy snake combined with different sensory stimuli, we demonstrated that noxious mechanical force is a key stimulus to evoke defensive attack (Figure 1). The pivotal role of noxious mechanical force in defensive attack was further supported by the reduction of biting attacks in mice with genetic ablation of Mrgprd+ sensory neurons, which may mediate behavioral responses to noxious mechanical stimuli (Cavanaugh et al., 2009). By contrast, snake feces coated on the dummy snake to provide predator-derived olfactory cues (Isogai et al., 2011) failed to evoke defensive attack. Instead, the olfactory cues promoted other defensive responses (e.g. freezing, risk assessment and avoidance), an observation consistent with previous studies (Papes et al., 2010; Wang et a., 2018).

AHN vGAT+ neurons are critical for mechanically-evoked defensive attack

The MHZ has been proposed to play a critical role in anti-predator defensive behaviors (Canteras et al., 1997; Canteras et al., 2002), thus prompting us to seek for mechanisms underlying mechanically-evoked defensive attack in this brain area. We found that the activities of AHN vGAT+ neurons in the MHZ are selectively required for mechanically-evoked defensive attack (Figure 2). These neurons optimally responded to noxious mechanical stimuli, and their activities encode the intensity of mechanical force delivered onto the contralateral side of the body (Figure 3). Then why do these neurons respond to noxious mechanical stimuli? We found that AHN vGAT+ neurons were

304 monosynaptically innervated by the LPB and PVT (Figure S8), two brain areas directly

305 innervated by TAC1+ spinal neurons for pain-related defensive behaviors (Huang et al.,

306 2019). Together, these results suggested that AHN vGAT+ neurons may be a critical

307 circuit module for mechanically-evoked defensive attack.

Activation of AHN vGAT+ neurons evokes biting attack to non-social targets

309 To further test the role of AHN vGAT+ neurons in defensive attack, we systematically

310 measured photostimulation-induced mouse behaviors to a series of experimental targets.

311 Light-stimulation of AHN vGAT+ neurons evoked biting attack toward predator (Figure

312 4F) and neutral object (Figure S9J). However, activation of these neurons failed to evoke

313 social attack toward conspecifics (Figure S10); on the contrary, their activation

314 suppressed social attack to male intruder in the paradigm of social aggression (Figure

315 4J). These observations indicated that activation of AHN vGAT+ neurons has not broadly

316 provoked an aggressive state that drives the mice to attack any targets without

317 target-specificity. In addition, these observations may be explained by our anatomical

318 finding that one efferent projection of AHN vGAT+ neurons terminates in the VMHvl

319 (inset of Figure S12E). The AHN vGAT+ neurons may presumably exert GABAergic

320 inhibition to VMHvl neurons, which are causally linked to social aggression (Lin et al.,

321 2011; Lee et al., 2014; Falkner et al., 2016; Yang et al., 2017).

322 Another interesting observation is that activation of AHN vGAT+ neurons triggered

323 biting attack toward predator, while suppressing other forms of defensive behavior, such

324 as risk assessment (Figure 4G), avoidance (Figure S9B) and freezing (Figure S9C).

325 These results suggested that AHN vGAT+ neurons may prioritize defensive attack above

326 other forms of defensive behavior by a "brake" mechanism. Indeed, we found that AHN

327 vGAT+ neurons project to the VMHdm and PMd (Figure S12, E and F). It is likely that

328 AHN vGAT+ neurons may exert GABAergic inhibition to neurons in the VMHdm and

329 PMd, which are involved in defensive behaviors such as freezing and avoidance (Silva et

330 al., 2013; Wang et al., 2015; Kunwar et al., 2015; Cezario et al., 2008).

New Questions

Our results also raise several new questions. First of all, although noxious mechanical stimuli optimally activated vGAT+ AHN neurons, predator-derived olfactory cues also modulated their activities (Figure 3G and 3H). Moreover, these neurons receive sparse monosynaptic innervations from the MA (Figure S8D3), which convey olfactory signals from the accessory olfactory bulb to the hypothalamus (Isogai et al., 2011). How AHN vGAT+ neurons participate in olfaction-mediated defensive behaviors would be an interesting topic to pursue in future study.

Second, our results do not rule out the role of AHN vGAT+ neurons in social behavior. Earlier studies using lesion and electrical stimulation techniques suggested that the AHN in other species may participate in intraspecific aggression (Rat: Olivier et al., 1983; Cat: Fuchs et al., 1985; Hamster: Delville et al., 2000; Prairie Voles: Gobrogge et al., 2007; Finch: Goodson et al., 2012). In this study, optogenetic activation of vGAT+ AHN neurons significantly increased time for social investigation in a social context (Figure 4K; Figure S10, E and J). The exact role of AHN vGAT+ neurons in social behaviors of mice needs to be tested in future study.

Finally, vGAT+ neurons represent a large neuronal population in the AHN. In future study, it would be important to identify more specific genetic markers to define subtypes of AHN vGAT+ neurons by using single-cell RNA sequencing approach. With Cre lines associated with more specific genetic markers, one would be able to better dissect how AHN vGAT+ neurons mediate mechanically-evoked defensive attack.

SUPPLEMENTARY INFORMATION

Supplementary information includes Methods, 16 figures, 4 tables and 15 movies.

AUTHOR CONTRIBUTIONS

P.C., C.Z., Z.Z., F.Z. conceived the study. Z.X. did injections and fiber implantation. H.G., X.C., T.T., Y.X. did behavioral tests. C.S., H.G. did EMG recording. H.G. did fiber photometry recording. Z.X., X.C., M.H. did histological analyses. M.H. maintained the snake. C.S. and H.G. did slice physiology. J.Z., W.L., Z.Z., F.Z., Z.T. provided reagents. D.L., C.S., H.G., Z.X., and P.C. analyzed data. P.C. wrote the manuscript.

LEGENDS

Figure 1 Noxious mechanical stimulus to evoke defensive attack in mice.

(**A**) An example picture showing a plastic dummy snake equipped with an alligator-clip to apply noxious mechanical stimulus (arrow) to mouse tail. (**B-D**) Behavioral ethograms of WT mice exposed to a dummy snake only (B), a dummy snake coated with snake feces (C), and a dummy snake equipped with an alligator-clip to apply noxious mechanical stimulus to mouse tail (D). The colored bars in the ethograms indicated the onset and offset of specific behaviors. (**E**) Time spent for attack by biting the dummy snake with and without snake feces. (**F**) Time spent for attack by biting the dummy snake with and without the alligator-clip to apply noxious mechanical stimulus. (**G**) Example micrographs of DRG of Mrgprd-CreERT2/iDTR/Ai3 mice treated with saline or Diphtheria toxin. (**H, I**) Time spent for attack in mice with and without ablation of putative Mrgprd+ DRG neurons evoked by noxious mechanical stimulus on tail (H) or on left forelimb (I). Number of mice was indicated in the graphs (E, F, H, I). Data in (E, F, H, I) are means ± SEM (error bars). Statistical analyses in (E, F, H, I) were performed by Student t-tests (** $P < 0.01$; *** $P < 0.001$). For the P values, see Table S4.

Figure 2 Xie et al., 2020

Figure 2 AHN vGAT+ neurons are required for mechanically-evoked defensive attack.

(**A**) Schematic diagram of bilateral photoinhibition of AHN vGAT+ or vGlut2+ neurons. For the micrographs with the optic fiber tracks, see Figure S5A and S5B. For the analyses of cell-type specificity, see Figure S5C-S5F. (**B**) Schematic diagram (*left*) and example trace (*right*) showing photoinhibition of AHN neurons expressing GtACR1. (**C**) Schematic diagram showing EMG recording from masseter muscles of mice. (**D-F**) Example traces (D) and quantitative analyses of biting bout number (E) and total biting time (F) within laser OFF phase and ON phase, showing the effect of photoinhibition of vGAT+ AHN neurons on mechanically-evoked biting attack. Mice with EGFP expressed in AHN vGAT+ neurons were used as a control for GtACR1. (**G-I**) Example traces (G) and quantitative analyses of biting bout number (H) and total biting time (I) within phases of laser OFF and ON, showing the effect of photoinhibition of AHN vGlut2+ neurons on mechanically-evoked biting attack. Mice with EGFP expressed in AHN vGlut2+ neurons were used as a control for GtACR1. For the effect of photoinhibition of AHN vGAT+ neurons on locomotion speed of freely-moving mice, see Figure S5H. Number of mice was indicated in the graphs (E, F, H, I). Data in (E, F, H, I) are means ± SEM (error bars). Statistical analyses in (E, F, H, I) were performed by Student t-tests (n.s. $P>0.1$, *** $P < 0.001$). For the P values, see Table S4.

Figure 3 Xie et al., 2020

Figure 3 AHN vGAT+ neurons encode mechanical stimuli.

(**A**) An example micrograph showing jGCaMP7s expressed in the AHN of vGAT-IRES-Cre mice and the optical fiber track above the AHN. For the analyses of cell-type specificity of jGCaMP7s expression, see Figure S6A and S6B. (**B**) Normalized GCaMP fluorescence changes (ΔF/F) in response to noxious mechanical stimulus on the tail. Inset, the head-fixed awake mouse standing on a treadmill was applied with noxious mechanical stimulus by tail clamping with an alligator-clip. (**C**) Quantitative analyses of peak GCaMP responses of AHN vGAT+ neurons in seven behavioral tests. The example trace for the test of "Mechanical stimulus" was in Figure 3B, while the other six example traces were in Figure S6C-S6H. (**D**) Schematic diagram of optrode recording from AHN vGAT+ neurons expressing ChR2-mCherry. For an example micrograph showing the optical fiber track and electrolytic lesion of recording site in the AHN, see Figure S7A. The principal component analysis for spike sorting of an example unit was in Figure S7B. (**E**) Raster and peri-stimulus time histogram (PSTH) of an example putative AHN vGAT+ neuron with spiking latency less than 5 ms relative to the onset of light pulses. (**F**) Correlation analysis of action potentials of individual units evoked either by light pulses (Light) or by mechanical stimuli (Mech), confirming a segregation between optogenetically identified units (Identified, red) and unidentified units (Unidentified, grey). (**G**) Heat-map PSTH of Z-scored firing rates of individual AHN vGAT+ neurons to mechanical stimuli (Mech) or olfactory stimuli (Olfac). For the schematic diagrams showing the application of mechanical stimuli and olfactory stimuli to the test mice, see Figure S7C and S7E. For the example units of putative AHN vGAT+ neurons in response to mechanical stimuli and olfactory stimuli, see Figure S7D and S7F. (**H**) Average PSTH of Z-scored firing rates of all identified AHN vGAT+ neurons to mechanical stimuli (Mech, red) and olfactory stimuli (Olfac, blue). (**I**) Heat-map PSTH of Z-scored firing rates of individual AHN vGAT+ neurons to mechanical stimuli applied with von Frey filaments (1 g, 100 g). For the schematic diagram showing the application of von Frey filaments to the test mice, see Figure S7G. For the heat-map PSTH of Z-scored firing rates of individual AHN vGAT+ neurons to 10 g mechanical stimuli, see Figure S7H. (**J**) Average PSTH of Z-scored firing rates of all identified AHN vGAT+ neurons to mechanical force with different intensities. (**K**) Averaged peak Z-scored firing rates of all identified AHN vGAT+ neurons to mechanical stimuli (100 g) on different body parts. (**L**) Averaged peak Z-scored firing rates of all identified AHN vGAT+ neurons to four repetitive mechanical stimuli (100 g) applied at 0.1 Hz and 0.5 Hz on the tail. Number of mice (C) and number of units (H, J, K, L) were indicated in the graphs. Data in (B, C, H, J, K, L) are means ± SEM (error bars). Statistical analyses were performed by Student t-tests (C, K) and One-Way ANOVA (H, J, L) (*** $P < 0.001$). For the P values, see Table S4.
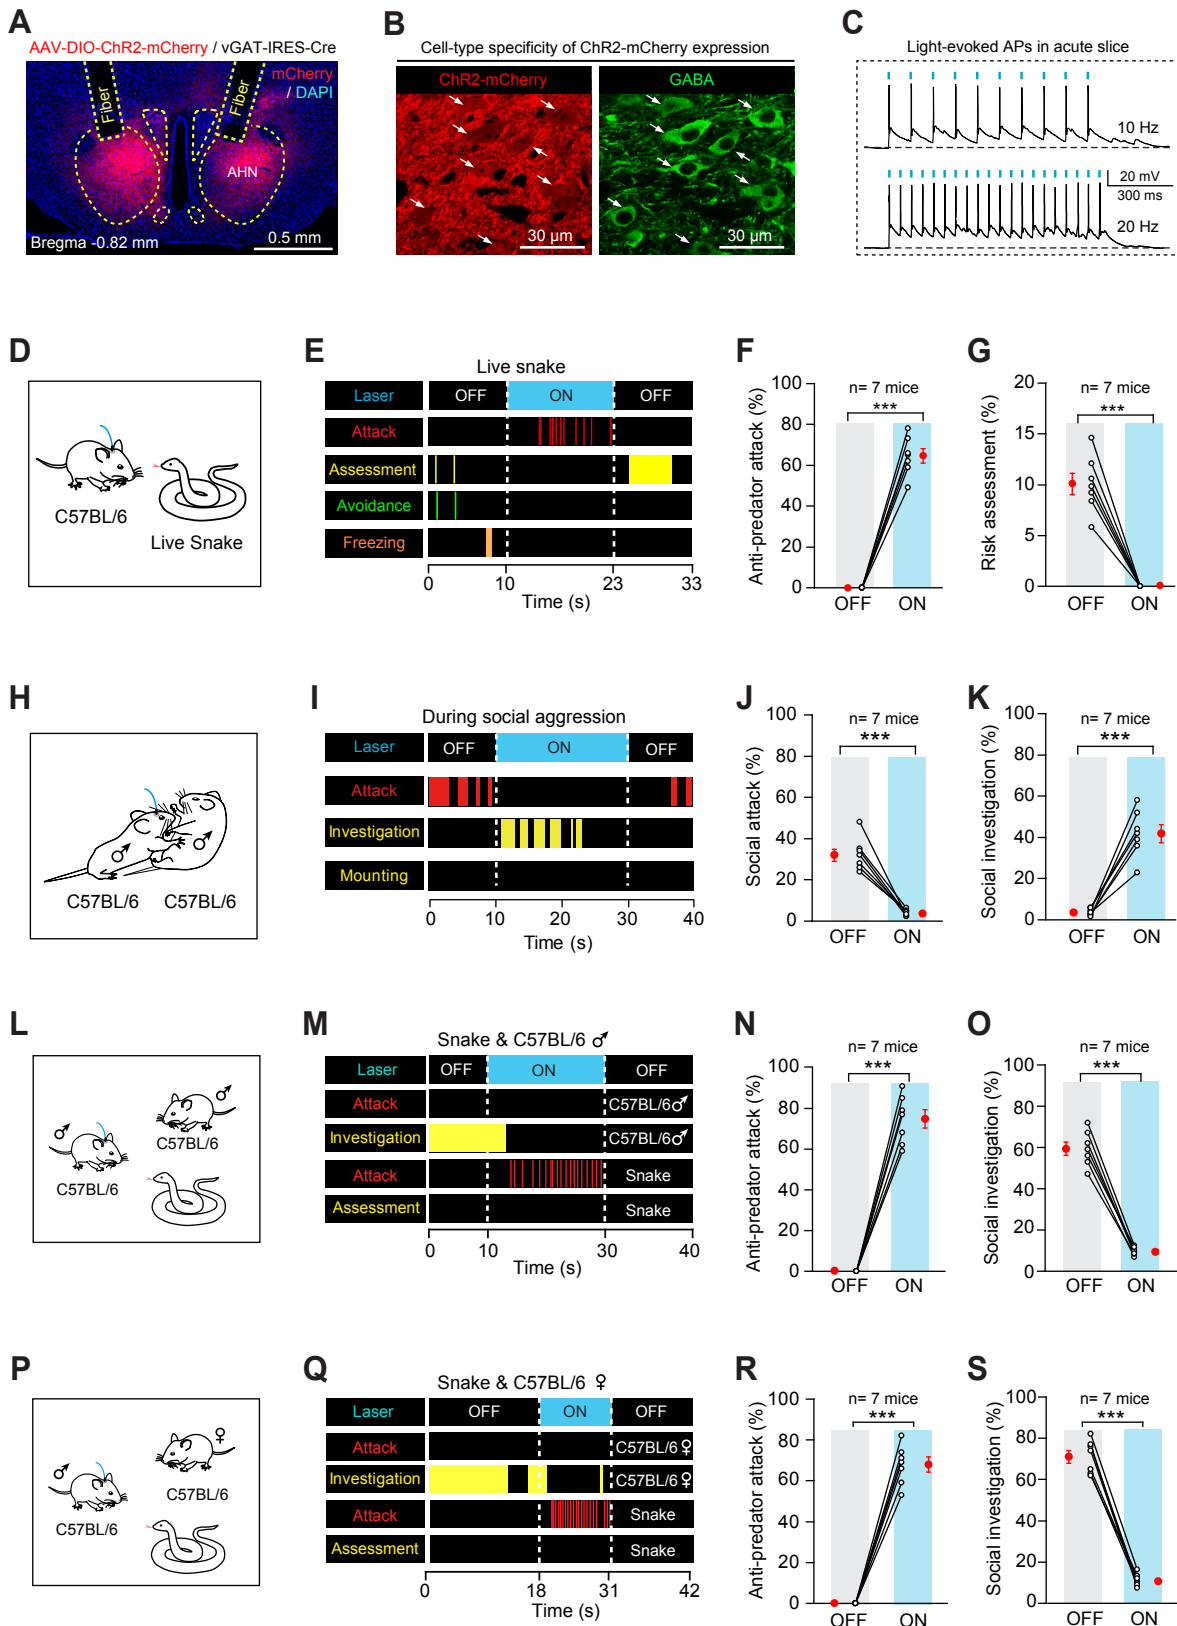

Figure 4 Xie et al., 2020

Figure 4 Activation of AHN vGAT+ neurons trigger biting attack to non-social targets.

(**A**) An example coronal section showing ChR2-mCherry expression in the AHN of vGAT-IRES-Cre mice and bilateral optical fiber tracks above the AHN. (**B**) Example micrographs showing the cell-type specificity of ChR2-mCherry expression in GABA+ AHN neurons. Arrows indicated soma of GABA+ cells expressing ChR2-mCherry. For the quantitative analysis, see Figure S9A. (**C**) Light-pulse trains (473 nm, 2 ms, 10 mW, 10 Hz or 20 Hz) reliably evoked phase-locked spiking activity in ChR2-mCherry+ AHN cells. (**D**) Schematic diagram showing a test mouse confronted with a live snake in the arena. (**E-G**) Example behavioral ethogram (E), quantitative analyses of time for anti-predator attack (F) and time for risk assessment (G) of mice before (OFF) and during (ON) photostimulation of AHN vGAT+ neurons. For quantitative analyses of time for freezing and avoidance, see Figure S9B and S9C. The colored bars in the ethograms indicated the onset and offset of specific behaviors. (**H**) Schematic diagram showing a test mouse exhibiting social aggression toward a male intruder. (**I-K**) Example behavioral ethogram (I), quantitative analyses of time for social attack (J) and time for social investigation (K) of mice before (OFF) and during (ON) photostimulation of AHN vGAT+ neurons. For more behavioral analyses, see Figure S10. (**L**) Schematic diagram showing a test mouse confronted with a live snake and a male C57BL/6 mouse in the arena. (**M-O**) Example behavioral ethogram (M), quantitative analyses of time for anti-predator attack (N) and time for social investigation (O) of test mice before (OFF) and during (ON) photostimulation of AHN vGAT+ neurons. For more behavioral analyses, see Figure S11 A-S11D. (**P**) Schematic diagram showing a test mouse confronted with a live snake and a female C57BL/6 mouse in the arena. (**Q-S**) Example behavioral ethogram (Q), quantitative analyses of time for anti-predator attack (R) and time for social investigation (S) of test mice before (OFF) and during (ON) photostimulation of AHN vGAT+ neurons. For more behavioral analyses, see Figure S11E-S11H. Number of mice was indicated in the graphs (F, G, J, K, N, O, R, S). Data in (F, G, J, K, N, O, R, S) are means ± SEM (error bars). Statistical analyses in (F, G, J, K, N, O, R, S) were performed by Student t-tests (*** $P < 0.001$). For the P values, see Table S4.

Figure 5 Role of vGAT+ AHN-PAG pathway for mechanically-evoked defensive attack.

(**A**) Schematic diagram showing AAV injection and optic fiber implantation for light stimulation of vGAT+ AHN-vlPAG pathway. For the example micrographs of the AHN and vlPAG, see Figure S13, A and B. (**B, C**) Example behavioral ethogram (B) and quantitative analysis of time for anti-predator attack (C) of mice before (OFF) and during (ON) activation of vGAT+ AHN-PAG pathway. For more behavioral analyses, see Figure S13C-S13E. For the analyses of vGAT+ AHN-LS pathway, see Figure S14. The colored bars in the ethograms indicated the onset and offset of specific behaviors. (**D**) Schematic diagram showing AAV injection into the AHN, optical fiber implantation above the AHN, and cannulae implantation above the vlPAG in vGAT-IRES-Cre mice. For the example micrographs with the optic fiber track and cannulae track above the AHN and vlPAG, see Figure S15A and S15B. (**E, F**) Example traces of postsynaptic currents (PSCs) recorded from vlPAG neurons (E) and quantitative analyses of their amplitude (F) showing the GABAergic action of vGAT+ AHN-PAG pathway is mediated by GABAa receptor. For the schematic diagram for slice physiology, see Figure S15C. (**G, H**) Quantitative analyses of light-evoked biting attack to live snake in mice with vlPAG treated with different doses of PTX (G) or saline (H). For the example behavioral ethograms, see Figure S15E and S15F. (**I**) Schematic diagram showing AAV injection and optic fiber implantation for photoinhibition of vGAT+ AHN-vlPAG pathway. For example micrographs of the AHN and vlPAG, see Figure S16A and S16B. (**J, K**) Quantitative analyses of biting bout number (J) and total biting time (K) toward dummy snake within phases of laser OFF and ON, showing the effect of photoinhibition of vGAT+ AHN-vlPAG pathway on mechanically-evoked biting attack. Mice with EGFP expressed in AHN vGAT+ neurons were used as a control for GtACR1. For example traces, see Figure S16C. Number of mice (C, G, H, J, K) and cells (F) were indicated in the graphs. Data in (C, F, G, H, J, K) are means ± SEM (error bars). Statistical analyses in (C, F, G, H, J, K) were performed by Student t-tests (n.s. P>0.1; ** P < 0.01; *** P < 0.001). For the P values, see Table S4.

METHODS

Animals

All experimental procedures were conducted following protocols approved by the Administrative Panel on Laboratory Animal Care at the National Institute of Biological Sciences, Beijing (NIBS). The *vGlut2-ires-Cre* (Vong et al., 2011), *vGAT-ires-Cre* (Vong et al., 2011), Mrgprd-CreERT2 (Olson et al., 2017), Ai3 (Madisen et al., 2010) and Rosa26-iDTR (Buch et al., 2005) mouse lines were imported from the Jackson Laboratory (JAX Mice and Services). Mice were maintained on a circadian 12-h light/12-h dark cycle with food and water available ad libitum. Mice were housed in groups (3–5 animals per cage) before they were separated three days prior to virus injection. After virus injection, each mouse was housed in one cage for three weeks before subsequent experiments. To avoid potential sex-specific differences, we used male mice only.

The Wistar rats were purchased from Charles River Laboratories in China. The hamsters used in this study were offspring of wild greater long-tailed hamsters (Tscherskia triton) captured in northeast of China in 2005. The rats and hamsters were individually housed and maintained on a circadian 12-h light/12-h dark cycle with food and water available ad libitum.

The live snake (*Elaphe schrenckii*) used in this study were purchased from online pet stores (www.taobao.com). After arrival from shipment, the snakes were individually maintained in glass box (35 cm x 35 cm x 35 cm) with regular bedding at 24ºC. They were fed every twenty-four hours with rodents after euthanasia by CO_2 inhalation. For mouse-versus-snake paradigm, one-month-old snake (20-30 g) was used. For rat-versus-snake and hamster-versus-snake paradigms, three-month-old snake (300-500 g) was used.

AAV vectors

649   The AAV serotype used in the present study is AAV2/9. The AAVs used in the present

650   study are listed in Table S1. The plasmid for pAAV-EF1α-DIO-ChR2-mCherry (Addgene

651   #20297) was from Deisseroth Lab. The plasmid for pFUGW-hGtACR1-2A-EGFP

652   (Addgene #67795) was from Spudich Lab. The cDNA for AAV- EF1α-DIO-jGCaMP7s

653   was from Kim Lab (Addgene #104463). AAV-EF1α-DIO-SynaptoTag was from Thomas

654   Südhof Lab at Stanford University. The viral particles were prepared by Taitool Inc. and

655   BrainVTA Inc. The produced viral vector titers before dilution were in the range of

656    $0.8-1.5×10^{13}$ viral particles/ml. The final titer used for AAV injection is $5×10^{12}$ viral

657   particles/ml.

Stereotaxic injection

659   Mice were anesthetized with an intraperitoneal injection of tribromoethanol (125–250

660   mg/kg). Standard surgery was performed to expose the brain surface above the anterior

661   hypothalamic nucleus (AHN). Coordinates used for AHN injection were: bregma -0.82

662   mm, lateral ± 0.50 mm, and dura -4.40 mm. The AAVs were stereotaxically injected with

663   a glass pipette with 8° angle from the lateral to medial. The injection was performed with

664   the pipette connected to a Nano-liter Injector 201 (World Precision Instruments, Inc.) at a

665   slow flow rate of 0.15 µl / min to avoid potential damage to local brain tissue. The pipette

666   was withdrawn at least 20 min after viral injection. For fiber photometry experiments,

667   AAV injections were unilateral and were followed by ipsilateral optical fiber implantation

668   (see "Optical fiber implantation"). For optogenetic activation/inactivation experiments,

669   AAV injections were bilateral and were followed by bilateral optical fiber implantation.

Optical fiber implantation

671   Thirty minutes after the AAV injection, a ceramic ferrule with an optical fiber (230 µm

672   in diameter, N.A. 0.37) was implanted with the fiber tip on top of the AHN [unilateral:

673   (bregma -0.82 mm, lateral +0.4 mm, dura -5.00 mm); bilateral: (bregma -0.82 mm, lateral

674   ± 1.25 mm, dura -5.00 mm, 8° angle from the lateral to medial)]. In some cases, the

675   optical fiber was implanted with the fiber tip on top of the LS (bregma 0.56 mm, lateral ±

0.40 mm, dura -2.90 mm, 8° angle from the lateral to medial) or vlPAG (bregma -4.30 mm, lateral ± 0.70 mm, dura -1.95 mm, 18° angle from the lateral to medial). The ferrule was then secured on the skull with dental cement. After implantation, the skin was sutured, and antibiotics were applied to the surgical wound. The optogenetic and fiber photometry experiments were conducted at least three weeks after optical fiber implantation. All experimental designs related to optical fiber implantation are summarized in Table S2.

For optogenetic manipulations, the output of the laser was measured and adjusted to 2, 5, 10 mW before each experiment. The pulse onset, duration, and frequency of light stimulation were controlled by a programmable pulse generator attached to the laser system. After AAV injection and fiber implantation, the mice were housed individually for three weeks before the behavioral tests.

Preparation of the behavioral tests

Before the behavioral tests, the animals were handled daily by the experimenters for at least three days. On the day of the behavioral test, the animals were transferred to the testing room and were habituated to the room conditions for 3 h before the experiments started. The apparatus was cleaned with 20% ethanol to eliminate odor cues from other animals. All behavioral tests were conducted during the same circadian period (13:00–19:00). All behaviors were scored by the experimenters, who were blind to the animal treatments.

Rodent-versus-snake paradigm

Mouse-versus-snake paradigm was performed in an enclosed box (10 cm x 10 cm x 35 cm) without bedding. The arena was cleaned with 20% ethanol to eliminate odor cues from other mice. The mouse (20g - 30 g) was habituated in the arena for 10 minutes. Then a young snake (20 g - 30 g) was placed in the arena. Before predatory attack from the snake, the mice exhibited risk assessment and freezing. When the snake initiated predatory attack, the mice exhibited avoidance or jumping escape. When the snake

gripped the body parts of the mice with the teeth, the mice usually defensively attacked the snake by biting (Movie S1). The trial ended when the mouse stopped defensive attack.

Rat-versus-snake paradigm and hamster-versus-snake paradigm were performed in an enclosed box (25 cm x 25 cm x35 cm) without bedding. The arena was cleaned with 20% ethanol to eliminate odor cues from other animal. The rat (400 g - 500 g) or the hamster (300 g- 400 g) was habituated in the arena for 10 minutes. Then an adult snake (300 g - 500 g) was placed in the arena. Before predatory attack from the snake, the rat or the hamster exhibited freezing, risk assessment and avoidance. When the snake initiated predatory attack, the rat or the hamster exhibited avoidance or jumping escape. When the snake gripped the body parts of the rat or hamster with the teeth, they usually defensively attacked the snake by biting (Movie S2 and S3). The trial ended when the rat or hamster stopped defensive attack.

Measurement of defensive behaviors to dummy snake

The plastic dummy snake was purchased from a merchant in Tao-Bao online store (www.taobao.com). The dummy snake (30 g) was either coated with fresh snake feces to provide olfactory cues of snake or equipped with a head-like alligator-clip (3 g) to provide noxious mechanical stimuli. The mechanical force from the alligator-clip, measured with spring dynamometer, was ~ 366 grams. The mechanical stimuli were applied either on the tail or on the four limbs of mice. In some experiments (Figure S2, G-I), the ambient light in the behavioral box was switched on (Light+, ~50 lux) and off (Light-, ~0.002 lux) to measure the contribution of visual cues to mechanically-evoked defensive attack. In some experiments (Figure S3), neutral objects (wood block, plastic lid) were connected to alligator clip to examine whether mice exhibit defensive attack to neutral object in the presence of noxious mechanical stimuli.

The defensive responses of the mice to the dummy snake in the enclosed arena (25 cm x 25 cm x 35 cm) were recorded with a high-speed camera (160 frames / s). The

730 arena was cleaned with 20% ethanol to eliminate odor cues from other mice. The time

731 for freezing, risk assessment, avoidance and biting attack were measured by visual

732 inspection off-line and plotted with a behavioral ethogram (e.g. Figure 1, B-D).

733 **Genetic ablation of Mrgprd+ neurons**

734 To ablate Mrgprd+ neurons, a two-step strategy of drug injections was used. First,

735 tamoxifen was injected intraperitoneally for eight consecutive days at a dosage of 75

736 mg/kg in 14-day old Mrgprd-CreERT2/iDTR/Ai3 male mice. Tamoxifen injection at this

737 dosage at this developmental stage was shown to induce Cre expression in

738 Mrgprd-expressing DRG neurons with high specificity (88.1 ± 1%) and high efficiency

739 (92.9 ± 4.6%) (Olsen et al., 2017). Second, three weeks after the last dose of tamoxifen

740 injection, diphtheria toxin (DT) was injected intraperitoneally for three consecutive days

741 at a dosage of 4 mg/kg in the same group of mice. The defensive attack behavior to the

742 dummy snake was measured three weeks after the last dose of DT injection. The

743 efficiency of genetic ablation of Mrgprd+ neurons were tested by immunostaining of

744 EYFP in the dorsal root ganglions (DRG) at the lumbar and sacral segments.

745 **EMG electrode implantation and EMG recording**

746 To monitor jaw muscle activity, we implanted chronic EMG electrodes in the right

747 masseter muscles of the jaw. The EMG electrode was made with flexible multi-strand

748 stainless steel wires (A-M Systems, No. 793200). The insulation of a small segment of

749 the wire (~0.5 mm) was removed to expose the electrode to the muscle. During the

750 surgical procedure, the wires were threaded through and anchored with a knot on the

751 muscle. The wires were then threaded beneath the skin of mouse face and attached to

752 the ground electrodes at the base of the skull with dental cement. After 3 day of recovery

753 from surgery, mice were connected to flexible EMG connection cables and allowed to

754 adapt for at least 1 day. The EMG signals were recorded using a Microelectrode AC

755 Amplifier Model 1800 (A-M System), filtered (10–500 Hz EMG recordings) and digitized

756 at 250 Hz using the software Spike2. A flashing LED triggered by a 1-s square-wave

757   pulse was simultaneously recorded to synchronize the video and EMG signals. The

758   effects of photoinhibition (Figure 2, D-I; Figure 5, I-K) and photostimulation (Figure S9D

759   and S9E) of AHN vGAT+ neurons on defensive attack were examined in the present

760   study.

761   **Measuring the effects of GtACR1-mediated photoinhibition on defensive attack**

762   To test the effects of photoinhibition of vGAT+ and vGlut2+ AHN neurons on

763   mechanically-evoked defensive attack, we injected AAV-EF1α-DIO-GtACR1-2A-EGFP

764   into the AHN of *vGAT-IRES-Cre* or *vGlut2-IRES-Cre* mice bilaterally, followed by optical

765   fibers implanted above the injection sites bilaterally. Three weeks after AAV injection, the

766   mice were subjected to the regular procedure to test mechanically-evoked defensive

767   attack behavior. GtACR1-mediated photoinhibition was achieved by laser illumination

768   (473 nm, 2s-OFF/2s-ON, 10 mW) on GtACR1-expressing vGAT+ or vGlut2+ AHN

769   neurons during mechanically-evoked defensive attack. The duration and bout number of

770   mechanically-evoked biting toward the dummy snake, as read out by analyzing EMG

771   traces (Figure S5G), were analyzed off-line. In a control experiment, the locomotion

772   speed of freely-moving mice before and during photoinhibition of vGAT+ AHN neurons

773   was measured with the video recorded from a camera above the mice.

774   To test the effects of photoinhibition of vGAT+ AHN-vlPAG pathway on

775   mechanically-evoked defensive attack, we injected AAV-EF1α-DIO-GtACR1-2A-EGFP

776   into the AHN of *vGAT-IRES-Cre* mice bilaterally, followed by optical fibers implanted

777   above the vlPAG bilaterally. Six weeks after AAV injection, the mice were subjected to

778   the regular procedure to test mechanically-evoked defensive attack behavior.

779   GtACR1-mediated photoinhibition was achieved by laser illumination (473 nm,

780   2s-OFF/2s-ON, 10 mW) on GtACR1-expressing axon terminals of vGAT+ AHN neurons

781   during mechanically-evoked defensive attack. The duration and bout number of

782   mechanically-evoked biting toward the dummy snake, as read out by analyzing EMG

783   traces (Figure S5G), were analyzed off-line.

Fiber photometry recording

A fiber photometry system (ThinkerTech, Nanjing, China) was used for recording GCaMP signals from genetically identified neurons (Gunaydin et al., 2014). To induce fluorescence signals, a laser beam from a laser tube (488 nm) was reflected by a dichroic mirror, focused by a 10× lens (N.A. 0.3) and coupled to an optical commutator. A 2-m optical fiber (230 µm in diameter, N.A. 0.37) guided the light between the commutator and implanted optical fiber. To minimize photo bleaching, the power intensity at the fiber tip was adjusted to 0.02 mW. The jGCaMP7s (Dana et al., 2019) fluorescence was band-pass filtered (MF525-39, Thorlabs) and collected by a photomultiplier tube (R3896, Hamamatsu). An amplifier (C7319, Hamamatsu) was used to convert the photomultiplier tube current output to voltage signals, which were further filtered through a low-pass filter (40 Hz cut-off; Brownlee 440). The analogue voltage signals were digitalized at 100 Hz and recorded by a Power 1401 digitizer and Spike2 software (CED, Cambridge, UK).

AAV-hSyn-DIO-jGCaMP7s was stereotaxically injected into the AHN of *vGAT-ires-Cre* mice followed by optical fiber implantation above the AHN (see "Stereotaxic injection" and "Optical fiber implantation"). Three weeks after AAV injection, fiber photometry was used to record GCaMP signals from the cell bodies of vGAT+ AHN neurons in seven different behavioral tests (see below). A flashing LED triggered by a 1-s square-wave pulse was simultaneously recorded to synchronize the video and GCaMP signals. After the experiments, the optical fiber tip sites above the vGAT+ AHN neurons were histologically examined in each mouse.

Measuring GCaMP signals before and during mechanical stimuli

Head-fixed awake mice with the optical fiber connected to the fiber photometry system were allowed to stand on a circular treadmill. Then noxious mechanical stimuli were applied by the alligator clip to mouse tail while the GCaMP fluorescence was recorded. The GCaMP signals were measured by normalizing GCaMP fluorescence ($\Delta F/F$) and

aligned with the initiation of mechanical stimuli.

Measuring GCaMP signals before and during mechanically-evoked biting

Mice with the optical fiber connected to the fiber photometry system freely explored the arena for 10 min. Then the mouse tail was clamped by the alligator-clip connected to the dummy snake. The GCaMP fluorescence and mechanically-evoked biting-like attack were simultaneously recorded. The GCaMP signals were measured by normalizing GCaMP fluorescence ($\Delta F/F$) and aligned with the initiation of biting-like attack.

Measuring GCaMP signals before and during locomotion

Head-fixed awake mice with the optical fiber connected to the fiber photometry system were allowed to stand on a circular treadmill. The spontaneous locomotion and the GCaMP fluorescence were simultaneously recorded. The GCaMP signals were measured by normalizing GCaMP fluorescence ($\Delta F/F$) and aligned with the initiation of locomotion.

Measuring GCaMP signals before and during risk assessment

Mice with optical fibers connected to the fiber photometry system freely explored the arena for 10 min. Then a live snake was introduced to the arena while the GCaMP signals and risk assessment were simultaneously recorded. The GCaMP signals were measured by normalizing GCaMP fluorescence ($\Delta F/F$) and aligned with the initiation of risk assessment.

Measuring GCaMP signals before and during object exploration

Mice with optical fibers connected to the fiber photometry system freely explored the arena for 10 min. Then a wood block (3 cm x 3 cm x 3 cm) was introduced to the arena while the GCaMP signals and object exploration were simultaneously recorded. The GCaMP signals were measured by normalizing GCaMP fluorescence ($\Delta F/F$) and aligned with the initiation of object exploration.

Measuring GCaMP signals before and during social investigation

837   Mice with optical fibers connected to the fiber photometry system freely explored the

838   arena for 10 min. Then a male or female C57BL/6 mouse was introduced to the arena

839   while the GCaMP signals and social investigation were simultaneously recorded. The

840   GCaMP signals were measured by normalizing GCaMP fluorescence (ΔF/F) and aligned

841   with the initiation of social investigation.

842   **Single-unit recording with optrode**

843   An optrode was used to identify the single-unit activity of vGAT+ AHN neurons.

844   AAV2/9-hSyn-DIO-ChR2-mCherry was injected into the AHN of vGAT-ires-Cre mice.

845   Three weeks after viral injection, single-unit recording was performed with an optrode in

846   the AHN of head-fixed awake mouse standing on the treadmill. The single-channel

847   optrode was made by assembling an optic fiber (230 µm) parallel with a glass-coated

848   tungsten electrode (1–3 MΩ). The distance between the two tips was ~200 µm. The

849   optrode was vertically advanced into the AHN with a Narishige micro-manipulator so that

850   the tungsten electrode tip was in the AHN while the optic fiber was above the AHN,

851   which minimized damage to the AHN by the optic fiber (Figure S7A). The spikes were

852   amplified by a differential amplifier (Model 1800, A-M Systems, Everett, WA, USA),

853   digitized (10 kHz) and stored by Spike2 software (Version 7.03). When the spikes from

854   mechanically-responsive units were isolated, a train (10 Hz, 1 sec) of light stimulations (1

855   ms) was delivered to test if the units were from ChR2-expressing neurons, which are

856   presumably vGAT+. The spikes from putative vGAT+ neurons had to conform to two

857   criteria: first, their latency to the light pulse should be less than 5 ms; second, their

858   waveform should be similar to that of spikes evoked by sensory stimulation. Only units

859   with spikes faithfully following the light stimulations with latency less than 5 ms were

860   further tested for sensory-evoked responses. The spike sorting was performed with

861   Spike2 Software (Version 7.03) in accordance with our previous work (Shang et al.,

862   2015). For a certain train of action potential, after setting the threshold of the spikes,

863   Spike2 automatically generated the templates and performed the spike-sorting. The

864 quality of spike clustering was further confirmed by principal component analysis (Figure

865 S7B). During single-unit recording, the application of mechanical and olfactory stimuli by

866 the experimenter was recorded by a video camera. A flashing LED triggered by a 1-s

867 square-wave pulse was simultaneously recorded to synchronize the video and

868 single-unit recording.

869 **Mechanical and olfactory stimuli**

870 When the single-unit activity of putative vGAT+ AHN units was isolated, we applied

871 mechanical or olfactory stimuli to the test mice. Mechanical stimuli were applied either by

872 alligator-clip (Figure S7C) or by Von Frey Filaments (Figure S7G). The alligator-clip that

873 clamped mouse tail generated mechanical force (~366 grams), which was measured by

874 two spring dynamometers connected to the two jaws of alligator-clip directing toward the

875 opposite directions. Three Von Frey Filaments with graded mechanical force (1 g, 10 g,

876 and 100 g) were used to poke different body parts of mice. To examine whether AHN

877 vGAT+ neurons also respond to mechanical stimuli applied on other parts of the body,

878 we used Von Frey filament (100 g) to poke four limbs of the mouse. To examine

879 adaptation of AHN vGAT+ neurons to repetitive mechanical stimuli, Von Frey filament

880 (100 g) were used to poke the tail of the test mice four times at a certain frequency (0.1

881 Hz or 0.5 Hz). To mimic olfactory cues of predator, fresh snake feces were coated on a

882 cotton swab and presented to the test mice with a distance of 2 cm between cotton swab

883 and the nose tip (Figure S7E).

884 **Verification of recording sites**

885 The recording sites of the putative vGAT+ AHN neurons were marked with electrolytic

886 lesions applied by passing positive currents (40 μA, 10 s) through the tungsten electrode.

887 Under deep anesthesia with urethane, the brain was perfused with saline and PBS

888 containing 4% PFA. After regular histological procedure, frozen sections were cut at 40

889 μm in thickness and counterstained with DAPI for histological verification of recording

890 sites (Figure S7A).

Cell-type-specific RV tracing

891

892   The modified rabies virus based three-virus system was used for mapping the

893   whole-brain inputs to vGAT+ AHN neurons (Wickersham et al., 2007). All the viruses

894   included   AAV2/9-CAG-DIO-EGFP-2A-TVA   (5   x 10^{12} viral   particles/ml),

895   AAV2/9-CAG-DIO-RG (5 x 10^{12} viral particles/ml), and EnvA-pseudotyped, glycoprotein

896   (RG)-deleted and DsRed-expressing rabies virus (RV-EvnA-DsRed, RV) (5.0×10^8 viral

897   particles/ml), which were packaged and provided by BrainVTA Inc. (Wuhan, China). A

898   mixture of AAV2/9-CAG-DIO-EGFP-2A-TVA and AAV2/9-CAG-DIO-RG (1:1, 200 nl)

899   was stereotaxically injected into the AHN of vGAT-ires-Cre mice unilaterally. Two weeks

900   after AAV helper injection, RV-EvnA-DsRed (300 nl) was injected into the same location

901   in the AHN of vGAT-ires-Cre mice in a biosafety level-2 lab facility. Starter neurons were

902   characterized by the coexpression of DsRed and EGFP, which were restricted in the

903   AHN (Figure S6C).

904   One week after injection of rabies virus, mice were perfused with saline followed by

905   4% paraformaldehyde (PFA) in PBS. After 8 h of post-fixation in 4% PFA, coronal brain

906   sections at 40 μm in thickness were prepared using a cryostat (Leica CM1900). All

907   coronal sections were collected and stained with DAPI. The coronal brain sections were

908   imaged with an Olympus VS120 epifluorescence microscope (10x objective) and

909   analyzed with ImageJ. For quantifications of subregions, boundaries were based on the

910   mouse brain atlas (Paxinos and Franklin, 2001). We selectively analyzed the

911   retrogradely labeled dense areas. The factional distribution of total cells labeled by

912   rabies virus was measured (Figure S8F).

913   Cell-counting strategies

914   Cell-counting strategies are summarized in Table S3. For counting cells in the AHN,

915   we collected coronal sections (40 μm) from bregma -0.34 mm to bregma -1.34 mm for

916   each mouse. The outline of the AHN was according to the mouse brain atlas (Paxinos

917   and Franklin, 2001). We acquired confocal images (20x objective, Zeiss LSM 780)

34

918 followed by cell counting with ImageJ software. By combining fluorescent in situ

919 hybridization and immunohistochemistry, we counted the number of vGAT+ and vGlut2+

920 cells in the AHN (Figure S4, A-C) and calculated the percentages of vGAT+ and vGlut2+

921 neurons in the neuronal population labeled by EGFP (Figure S4, D-O). With

922 immunohistochemical staining of glutamate and GABA, we calculated the percentages

923 of glutamate[+] and GABA[+] neurons in the neuronal population labeled by EGFP (Figure

924 S5, C-F), GCaMP7 (Figure S6, A & B), or mCherry (Figure S9, A & B).

925 To analyze monosynaptic inputs of vGAT+ AHN neurons, we counted DsRed+ cells in

926 a series of brain areas (Figure S8, E & F). For counting cells in the LS, we collected

927 coronal sections (40 µm) from bregma +1.54 mm to bregma -0.10 mm. For counting cells

928 in the MPA, we collected coronal sections (40 µm) from bregma +0.74 mm to bregma

929 -0.58 mm for each mouse. For counting cells in the PVH, we collected coronal sections

930 (40 µm) from bregma -0.58 mm to bregma -1.22 mm. For counting cells in the SO, we

931 collected coronal sections (40 µm) from bregma -0.58 mm to bregma -0.94 mm. For

932 counting cells in the VMH, we collected coronal sections (40 µm) from bregma -1.06 mm

933 to bregma -2.06 mm. For counting cells in the DM, we collected coronal sections (40 µm)

934 from bregma -1.34 mm to bregma -2.18 mm. For counting cells in the MA, we collected

935 coronal sections (40 µm) from bregma -0.94 mm to bregma -2.18 mm. For counting cells

936 in the PVT, we collected coronal sections (40 µm) from bregma -0.22 mm to bregma

937 -2.18 mm. For counting cells in the PMD, we collected coronal sections (40 µm) from

938 bregma -2.46 mm to bregma -2.70 mm. For counting cells in the PMV, we collected

939 coronal sections (40 µm) from bregma -2.30 mm to bregma -2.54 mm. For counting cells

940 in the PH, we collected coronal sections (40 µm) from bregma -1.82 mm to bregma -2.70

941 mm. For counting cells in the S, we collected coronal sections (40 µm) from bregma

942 -2.46 mm to bregma -4.36 mm. For counting cells in the AHi, we collected coronal

943 sections (40 µm) from bregma -1.94 mm to bregma -3.80 mm. For counting cells in the

944 LPB, we collected coronal sections (40 µm) from bregma -4.96 mm to bregma -5.68 mm.

945 The outlines of these brain areas were according to the mouse brain atlas (Paxinos and
946 Franklin, 2001). We acquired fluorescent images (10x objective, Olympus) followed by
947 cell counting with ImageJ software.

948 **ChR2-mediated photostimulation of vGAT+ AHN neurons**

949 AAV-hSyn-DIO-ChR2-mCherry was bilaterally injected into the AHN of
950 *vGAT-IRES-Cre* mice, followed by optical fibers implanted bilaterally above the injection
951 sites. Three weeks after AAV injection, the vGAT+ AHN neurons were photostimulated
952 (473 nm, 10 mW, 20 Hz, 10~20 s) and mouse behaviors to different experimental targets
953 were examined.

954 **Measurement of behaviors to live predator**

955 The mice were habituated to the enclosed arena (25 cm x 25 cm) for 15 minutes per
956 day in consecutive three days before the behavioral test. On the fourth day, after the
957 mice entered the arena, they were first habituated to the arena for 15 minutes to
958 minimize anxiety and stress. Then a live snake (20 g - 30 g) was gently placed inside the
959 chamber. To minimize the possibility of predatory attack from the snake, the snake was
960 anaesthetized with isoflurane if necessary. A light-pulse train lasting 10~20 s (473 nm, 5
961 ms, 20 Hz, 10 mW) was delivered to stimulate vGAT+ AHN neurons that expressed
962 ChR2-mCherry. The defensive behaviors (risk assessment, freezing, avoidance,
963 biting-like attack) were recorded by the horizontal camera. A researcher blind to the
964 conditions of the mice analyzed the video by plotting a behavioral ethogram off-line. The
965 total time spent for defensive behaviors (risk assessment, freezing, avoidance, or
966 biting-like attack) was used for the quantitative analyses. In some cases (Figure S9, D
967 and E), we also measured the dependence of defensive attack on the frequency (5 Hz,
968 10 Hz, 20 Hz) and power (2 mW, 5 mW, 10 mW) of laser pulses.

969 **Measurement of behaviors to neutral object**

970 The mice were habituated to the enclosed (25 cm x 25 cm) for 15 minutes per day in
971 consecutive three days before the behavioral test. On the fourth day, after the mice

972 entered the arena, they were first habituated to the arena for 15 minutes to minimize

973 anxiety and stress. Then a wood block (3 cm x 3 cm x 3 cm) was gently placed inside the

974 chamber. For photostimulation of vGAT+ AHN neurons, a light-pulse train lasting 10~20

975 s (473 nm, 5 ms, 20 Hz, 10 mW) was delivered. Mouse behaviors (sniffing, avoidance,

976 freezing, biting-like attack) was recorded by the horizontal camera. A researcher blind to

977 the conditions of the mice analyzed the video by plotting a behavioral ethogram off-line.

978 The total time spent for these behaviors (sniffing, avoidance, freezing, biting-like attack)

979 was used for the quantitative analyses.

980 **Measurement of behaviors to conspecifics**

981 The mice were habituated to the arena (25 cm x 25 cm) for 15 minutes per day in

982 consecutive three days before the behavioral test. On the fourth day, after the mice

983 entered the arena, they were first habituated to the arena for 15 minutes to minimize

984 anxiety and stress. Then a male or female C57BL/6 mouse with similar age to the test

985 mice was gently placed inside the chamber. For photostimulation of vGAT+ AHN

986 neurons, a light-pulse train lasting 10~20 s (473 nm, 5 ms, 20 Hz, 10 mW) was delivered.

987 The social behaviors (social investigation, mounting, social attack) was recorded by the

988 horizontal camera. A researcher blind to the conditions of the mice analyzed the video by

989 plotting a behavioral ethogram off-line. The total time spent for social behaviors (social

990 investigation, avoidance, mounting, social attack) was used for the quantitative analyses.

991 We also tested how light-stimulation of AHN vGAT+ neurons influence social attack in

992 a paradigm of social aggression. A 1-month-old male C57BL/6 mouse was gently placed

993 inside the homecage of test mouse. For photostimulation of vGAT+ AHN neurons, a

994 light-pulse train lasting 10~20 s (473 nm, 5 ms, 20 Hz, 10 mW) was delivered. The social

995 behaviors (social investigation, mounting, social attack) was recorded by the vertical

996 camera. A researcher blind to the conditions of the mice analyzed the video by plotting a

997 behavioral ethogram off-line. The total time spent for social behaviors (social

998 investigation, avoidance, mounting, social attack) was used for the quantitative analyses.

Measurement of behaviors to conspecifics and live snake

The mice were habituated to the arena (25 cm x 25 cm) for 15 minutes per day in consecutive three days before the behavioral test. On the fourth day, after the mice entered the arena, they were first habituated to the arena for 15 minutes to minimize anxiety and stress. Then a live snake and a male (or female) C57BL/6 mouse with similar age to the test mice were gently placed inside the chamber together. For photostimulation of vGAT+ AHN neurons, a light-pulse train lasting 10~20 s (473 nm, 5 ms, 20 Hz, 10 mW) was delivered. The social behaviors (social investigation, mounting, social attack) and anti-predator defensive behaviors (freezing, risk assessment, avoidance, defensive attack) were recorded by the horizontal camera. A researcher blind to the conditions of the mice analyzed the video by plotting a behavioral ethogram off-line. The total time spent for each behavior was used for the quantitative analyses.

Cell-type-specific anterograde tracing of AHN vGAT+ neurons

For cell-type-specific anterograde tracing of vGAT+ AHN neurons, AAV-DIO-EGFP-Syb2 was stereotaxically injected into the AHN of vGAT-ires-Cre mice (200 nl). The mice were then maintained in a cage individually. Three weeks after viral injection, mice were perfused with saline followed by 4% paraformaldehyde (PFA) in PBS. After 8 h of post-fixation in 4% PFA, coronal brain sections at 40 μm in thickness were prepared using a cryostat (Leica CM1900). All coronal sections were collected and stained with primary antibody against EGFP and DAPI. The coronal brain sections were imaged with an Olympus VS120 epifluorescence microscope (10× objective lens).

Cannulae implantation of and drug infusion

A cannula was stereotaxically implanted above the ventrolateral periaqueductal gray (vlPAG). The inner and outer diameters of the cannula were 150 μm and 300 μm, respectively. The cannula was fixed to the skull using acrylic cement. During drug infusion, the cannula was connected with a catheter filled with the picrotoxin (PTX, 100 μM) or saline for injection. The other end of the catheter was connected to a Hamilton

1026 syringe (Hamilton, Reno, NV, USA) controlled by an infusion pump to drive the delivery

1027 of PTX or saline (50 nl / min). The delivery of PTX or saline was operated in a step-wise

1028 fashion, with 100 nl infused to the vlPAG in each step (0, 100, 200 nl).

1029 Photostimulation-induced anti-predator defensive behaviors were measured after each

1030 step of infusion was completed (0, 100, 200 nl). At the end of the experimental session,

1031 the test mice were perfused and the coronal brain sections containing vlPAG were

1032 inspected for the presence of cannula track. The mice with no cannula track above the

1033 vlPAG were rejected from further analysis.

1034 **Slice physiological recording**

1035 Slice physiological recording was performed according to the published work[55]. Brain

1036 slices containing the AHN or PAG were prepared from adult mice anesthetized with

1037 isoflurane before decapitation. Brains were rapidly removed and placed in ice-cold

1038 oxygenated (95% O_2 and 5% CO_2) cutting solution (228 mM sucrose, 11 mM glucose, 26

1039 mM $NaHCO_3$, 1 mM NaH_2PO_4, 2.5 mM KCl, 7 mM $MgSO_4$, and 0.5 mM $CaCl_2$). Coronal

1040 brain slices (400 μm) were cut using a vibratome (VT 1200S, Leica Microsystems,

1041 Wetzlar, Germany). The slices were incubated at 28°C in oxygenated artificial

1042 cerebrospinal fluid (ACSF: 119 mM NaCl, 2.5 mM KCl, 1 mM NaH_2PO_4, 1.3 mM $MgSO_4$,

1043 26 mM $NaHCO_3$, 10 mM glucose, and 2.5 mM $CaCl_2$) for 30 min, and were then kept at

1044 room temperature under the same conditions for 1 h before transfer to the recording

1045 chamber at room temperature. The ACSF was perfused at 1 ml/min. The acute brain

1046 slices were visualized with a 40× Olympus water immersion lens, differential interference

1047 contrast (DIC) optics (Olympus Inc., Japan), and a CCD camera.

1048 Patch pipettes were pulled from borosilicate glass capillary tubes (Cat #64-0793,

1049 Warner Instruments, Hamden, CT, USA) using a PC-10 pipette puller (Narishige Inc.,

1050 Tokyo, Japan). For recording of action potentials (current clamp), pipettes were filled

1051 with solution (in mM: 135 K-methanesulfonate, 10 HEPES, 1 EGTA, 1 Na-GTP, 4

1052 Mg-ATP, and 2% neurobiotin, pH 7.4). For recording of postsynaptic currents (voltage

1053 clamp), pipettes were filled with solution (in mM, 135 CsCl, 10 HEPES, 1 EGTA, 1

1054 Na-GTP, 4 Mg-ATP, pH 7.4). The resistance of pipettes varied between 3.0–3.5 MΩ.

1055 The current and voltage signals were recorded with MultiClamp 700B and Clampex 10

1056 data acquisition software (Molecular Devices). After establishment of the whole-cell

1057 configuration and equilibration of the intracellular pipette solution with the cytoplasm,

1058 series resistance was compensated to 10–15 MΩ. Recordings with series resistances of

1059 > 15 MΩ were rejected.

1060 An optical fiber (230 μm in diameter, N.A. 0.37) was used to deliver light pulses, with

1061 the fiber tip positioned 500 μm above the brain slices. Laser power was adjusted to 10

1062 mW. Light-mediated photoinhibition of GtACR1+ neurons was tested by a constant laser

1063 illumination (473 nm, 300 ms, 10 mW) while the neurons were depolarized (usually 0.1

1064 nA) to trigger action potential firing (Figure 2B). Light-evoked action potentials from

1065 ChR2-mCherry[+] neurons in the AHN were triggered by a light-pulse train (473 nm, 2 ms,

1066 10 Hz or 20 Hz, 10 mW) synchronized with Clampex 10 data acquisition software

1067 (Molecular Devices) (Figure 4C). Light-evoked postsynaptic currents from PAG neurons

1068 were triggered by single light pulses (2 ms) in the presence of 4-aminopyridine (4-AP, 20

1069 μM) and tetrodotoxin (TTX, 1 μM). D-AP5 (50 μM)/CNQX (20 μM) or picrotoxin (PTX, 50

1070 μM) were perfused with ACSF to examine the neurotransmitter type used by

1071 ChR2-mCherry-expressing AHN neurons (Figure 5, E and F).

1072 **RNA in situ hybridization**

1073 Mice were perfused with PBS treated with 0.1% DEPC (Sigma, D5758), followed by

1074 DEPC-treated PBS containing 4% PFA (PBS-PFA). Brains were post-fixed in

1075 DEPC-treated PBS-PFA solution overnight and then placed in DEPC-treated 30%

1076 sucrose solution at 4℃ for 30h. Brain sections to a thickness of 30 μm were prepared

1077 using a cryostat (Leica, CM3050S) and collected in DPEC-treated PBS. Fluorescence in

1078 situ hybridization (FISH) was performed as previously described (Chen et al., 2020) with

1079 minor modifications. Briefly, brain sections were rinsed with DPEC-treated PBS,

1080 permeabilized with DPEC-treated 0.1% Tween 20 solution (in PBS) and DPEC-treated 2
1081 × SSC containing 0.5% Triton. Brain sections were then treated with H2O2 solution and
1082 acetic anhydride solution to reduce nonspecific FISH signals. After 2h incubation in
1083 prehybridization buffer (50% formamide, 5 × SSC, 0.1% Tween20, 0.1% CHAPS, 5mM
1084 EDTA in DEPC-treated water) at 65℃, brain sections were then hybridized with the
1085 hybridization solution containing mouse antisense cRNA probes (digoxigenin labeling)
1086 for   vGlut2   (amplified   by   primers   CCAAATCTTACGGTGCTACCTC   and
1087 TAGCCATCTTTCCTGTTCCACT)   or   vGAT   (amplified   by   primers
1088 GCCATTCAGGGCATGTTC and AGCAGCGTGAAGACCACC) at 65°C for 20h.The
1089 sequences of cDNA primers for cRNA probes were the same as those in the ISH DATA
1090 of the Allen brain atlas (https://mouse.brain-map.org/). After washing, brain sections
1091 were incubated with Anti-Digoxigenin-POD, Fab fragments (1:400, Roche, 11207733910)
1092 at 4°C for 30 h, and FISH signals were detected using a TSA Plus Cyanine 3 kit
1093 (NEL744001KT, PerkinElmer). To detect the GFP signals, brain sections were incubated
1094 with a primary antibody against GFP(1:2000, Abcam ab290) at 4℃ for 24 h and then with
1095 an Alexa Fluor® 488-conjugated goat anti-rabbit secondary antibody (1:500, Invitrogen,
1096 A11034) at room temperature for 2h. Brain sections were mounted and imaged using a
1097 Zeiss LSM780 confocal microscope or the Olympus VS120 Slide Scanning System.

1098 **Immunohistochemistry**

1099 Mice were anesthetized with isoflurane and sequentially perfused with saline and
1100 phosphate buffered saline (PBS) containing 4% paraformaldehyde (PFA). Brains were
1101 removed and incubated in PBS containing 30% sucrose until they sank to the bottom.
1102 Post-fixation of the brain was avoided to optimize immunohistochemistry of GABA and
1103 glutamate. Cryostat sections (40 µm) were collected, incubated overnight with blocking
1104 solution (PBS containing 10% goat serum and 0.7% Triton X-100), and then treated with
1105 primary antibodies diluted with blocking solution for 3–4 h at room temperature. Primary
1106 antibodies used for immunohistochemistry are displayed in Table S1. Primary antibodies

were washed three times with washing buffer (PBS containing 0.7% Triton X-100) before incubation with secondary antibodies (tagged with Cy2, Cy3, or Cy5; dilution 1:500; Life Technologies Inc., USA) for 1 h at room temperature. Sections were then washed three times with washing buffer, stained with DAPI, and washed with PBS, transferred onto Super Frost slides, and mounted under glass coverslips with mounting media.

Sections were imaged with an Olympus VS120 epifluorescence microscope (10× objective lens) or a Zeiss LSM 710 confocal microscope (20× and 60× oil-immersion objective lens). Samples were excited by 488, 543, or 633 nm lasers in sequential acquisition mode to avoid signal leakage. Saturation was avoided by monitoring pixel intensity with Hi-Lo mode. Confocal images were analyzed with ImageJ software.

Analyses of cell-type specificity

Two types of experiments were performed to quantify cell-type specificity in the study. First, we tested the specificity of vGAT-IRES-Cre and vGlut2-IRES-Cre lines to label vGAT+ and vGlut2+ AHN neurons, by injecting AAV-DIO-EGFP into the AHN of these mice. Then we collected the tissue sections of AHN and analyzed the expression of vGAT/vGlut2 mRNA and EGFP were examined by RNA in situ hybridization and immunohistochemistry, respectively. The specificity and efficiency of vGAT-IRES-Cre and vGlut2-IRES-Cre mice to label vGAT+ and vGlut2+ neurons were calculated (Figure S4D-S4O).

Second, we tested whether the molecular tools (GtACR1-2A-EGFP, jGCaMP7s, ChR2-mCherry) were specifically expressed in GABAergic neurons in the AHN, by immunostaining of GABA with an anti-GABA antibody that has been validated in our previous studies (Shang et al., 2018). The cell-type specificity and efficiency for each molecular tool to express in vGAT+ AHN neurons was quantitatively analyzed (GtACR1-2A-EGFP: Figure S5C-S5F; jGCaMP7s: Figure S6A and S6B; ChR2-mCherry: Figure 4B and S9A).

Data quantification and statistical analyses

1134   All experiments were performed with anonymized samples in which the experimenter
1135   was unaware of the experimental conditions of the mice. For the statistical analyses of
1136   experimental data, Student t-test and One-Way ANOVA were used. The "n" used for
1137   these analyses represents number of mice or cells. See the detailed information of
1138   statistical analyses in figure legend and in Table S4. All statistical comparisons were
1139   conducted on data originating from three or more biologically independent experimental
1140   replicates. All data are shown as means ± SEM.

1141   **Data availability**

1142   The data that support the findings of this study are available from the corresponding
1143   author upon reasonable request.

Figure S7 Single-unit recording from AHN vGAT+ neurons with an optrode. (Related to Figure 3)

(A) An example coronal section showing ChR2-mCherry expression in the AHN of vGAT-IRES-Cre mice, and an optrode track above the AHN. Note the recording site was marked by electrolytic lesion (arrow) in the AHN. For the analyses of specific expression of ChR2-mCherry in GABA+ AHN neurons, see Figure 4B and Figure S9A.

(B) Principal component analysis of light-evoked spikes (blue dots) and mechanically-evoked spikes (black dots) of an example putative AHN vGAT+ neuron. Gray dots represent noise. Inset shows example waveforms of light-evoked spike (Light) and mechanically-evoked spike (Mech).

(C, E) Schematic diagrams showing the application of mechanical stimuli on the tail with an alligator-clip (C) and the application of olfactory stimuli by presenting cotton swab with snake feces (E) to the test mice.

(D, F) Raster plots of example units of putative vGAT+ AHN neurons showing their responses to mechanical stimuli (Mech) (D) and to cotton swab with snake feces (Feces) (F).

(G) A schematic diagram showing the application of von Frey Filaments poking different body parts of the test mice (tail, four limbs). Red dots indicated the site for poking.

(H) Heat-map PSTH of Z-scored firing rates of individual vGAT+ AHN neurons to mechanical stimuli applied with von Frey Filaments (10 g).

(I) Schematic diagrams showing the recording sites marked by electrolytic lesions were within the anterior part (AHA), central part (AHC) and posterior part (AHP) of the AHN.

Figure S8   Xie et al., 2020

116 **Figure S8 Retrograde tracing of AHN vGAT+ neurons by rabies virus. (Related to**
117 **Figure 3)**

118 **(A)** A series of schematic diagrams showing the strategy for monosynaptic retrograde
119 tracing of AHN vGAT+ neurons by using a combination of AAV and rabies virus (RV). *Left*,
120 a diagram showing AAV and RV for brain injection. *Middle*, a diagram showing the brain
121 area for injection. *Right*, a diagram showing the timing of AAV injection and RV injection.

122 **(B)** Example micrographs showing that the viral injection center, as indicated by the
123 co-expression of EGFP and DsRed, was localized in the AHN of vGAT-IRES-Cre mice.

124 **(C)** Example micrographs showing the expression of EGFP (green) and DsRed (red) at
125 the injection site within the AHN. Note the dually-labeled cells indicate starter cells.

126 **(D)** Example micrographs showing DsRed+ cells in different brain regions, including the
127 lateral parabrachial nucleus (LPB) (D1), the paraventricular thalamic nucleus (PVT) (D2),
128 the ventromedial hypothalamic nucleus (VMH) / dorsomedial hypothalamic nucleus (DM)
129 / medial amygdaloid nucleus (MA) (D3), the lateral septum (LS) / medial preoptic area
130 (MPA) (D4), the dorsal part of premammillary nucleus (PMD) / ventral part of
131 premammillary nucleus (PMV) / posterior hypothalamic area (PH) (D5), and the
132 subiculum (S) (D6).

133 **(E)** Fraction distribution of total DsRed-labeled cells in different brain regions
134 monosynaptically projecting to the vGAT+ AHN neurons.

135 Scale bars are labeled in the graphs. Numbers of mice (E) are indicated in the graphs.
136 Data in (E) are means ± SEM.

Figure S9 Xie et al., 2020

Figure S9 Additional quantitative analyses of behaviors evoked by activation of AHN vGAT+ neurons to live snake and wood block. (Related to Figure 4)

(A) Quantitative analyses showing specific expression of ChR2-mCherry in GABA+ AHN neurons. For the example micrographs, see Figure 4B.

(B, C) Quantitative analyses of time spent for avoidance (B) and freezing (C) with (ON) and without (OFF) light-stimulation of vGAT+ AHN neurons.

(D, E) Quantitative analyses of time spent for anti-predator attack evoked by light-stimulation with different frequencies (D) and with different laser powers (E) on AHN vGAT+ neurons.

(F) Example EMG traces of masseter muscles before (OFF) and during (ON) light stimulation of vGAT+ AHN neurons in the arena without a target (No target) or with a live snake (Snake). Shaded areas indicate the initiation and termination of biting-like attacks based on visual inspection of the video taken by high-speed camera.

(G) Quantitative analyses of biting bouts, as indicated by EMG, evoked by photostimulation of vGAT+ AHN neurons in the arena without a target (No target) or with a live snake (Snake).

(H) Schematic diagram showing the behavioral paradigm to measure mouse behaviors to a wood block in an enclosed arena.

(I) Behavioral ethogram of an example mouse to the wood block in the arena before, during and after light stimulation of AHN vGAT+ neurons. The colored bars in the ethograms indicated the onset and offset of specific behaviors.

(J, K) Quantitative analyses of time spent for attacking (J) and investigating (K) the wood block before (OFF) and during (ON) light stimulation of AHN vGAT+ neurons.

Scale bars are labeled in the graphs. Numbers of mice are indicated in the graphs (A-E, G, J, K). Data in (A-E, G, J, K) are means ± SEM. For the P values, see Table S4.

Figure S10 Xie et al., 2020

Figure S10 Additional quantitative analyses of behaviors evoked by activation of vGAT+ AHN neurons to conspecifics. (Related to Figure 4)

(A, F) Schematic diagrams showing the behavioral paradigm to measure mouse behaviors to male (A) and female conspecifics (F) in an enclosed arena.

(B, G) Behavioral ethograms of example mice to male (B) and female (G) conspecifics before, during and after photostimulation of AHN vGAT+ neurons. The colored bars in the ethograms indicated the onset and offset of specific behaviors.

(C, H) Quantitative analyses of time spent for social attack toward male (C) and female (H) conspecifics before (OFF) and during (ON) photostimulation of vGAT+ AHN neurons.

(D, I) Quantitative analyses of time spent for mounting on male (D) and female (I) conspecifics before (OFF) and during (ON) photostimulation of vGAT+ AHN neurons.

(E, J) Quantitative analyses of time spent for social investigation of male (E) and female (J) conspecifics before (OFF) and during (ON) photostimulation of vGAT+ AHN neurons.

Numbers of mice are indicated in the graphs (C-E, H-J). Data in (C-E, H-J) are means ± SEM. Statistical analyses were performed by Student *t*-tests (*, $P<0.05$; **, $P<0.01$). For the P values, see Table S4.

Figures

Figure 1

Noxious mechanical stimulus to evoke defensive attack in mice. (A) An example picture showing a plastic dummy snake equipped with an alligator-clip to apply noxious mechanical stimulus (arrow) to mouse tail. (B-D) Behavioral ethograms of WT mice exposed to a dummy snake only (B), a dummy snake coated with snake feces (C), and a dummy snake equipped with an alligator-clip to apply noxious

mechanical stimulus to mouse tail (D). The colored bars in the ethograms indicated the onset and offset of specific behaviors. (E) Time spent for attack by biting the dummy snake with and without snake feces. (F) Time spent for attack by biting the dummy snake with and without the alligator-clip to apply noxious mechanical stimulus. (G) Example micrographs of DRG of Mrgprd-CreERT2/iDTR/Ai3 mice treated with saline or Diphtheria toxin. (H, I) Time spent for attack in mice with and without ablation of putative Mrgprd+ DRG neurons evoked by noxious mechanical stimulus on tail (H) or on left forelimb (I). Number of mice was indicated in the graphs (E, F, H, I). Data in (E, F, H, I) are means ± SEM (error bars). Statistical analyses in (E, F, H, I) were performed by Student t-tests (** P < 0.01; *** P < 0.001). For the P values, see Table S4.

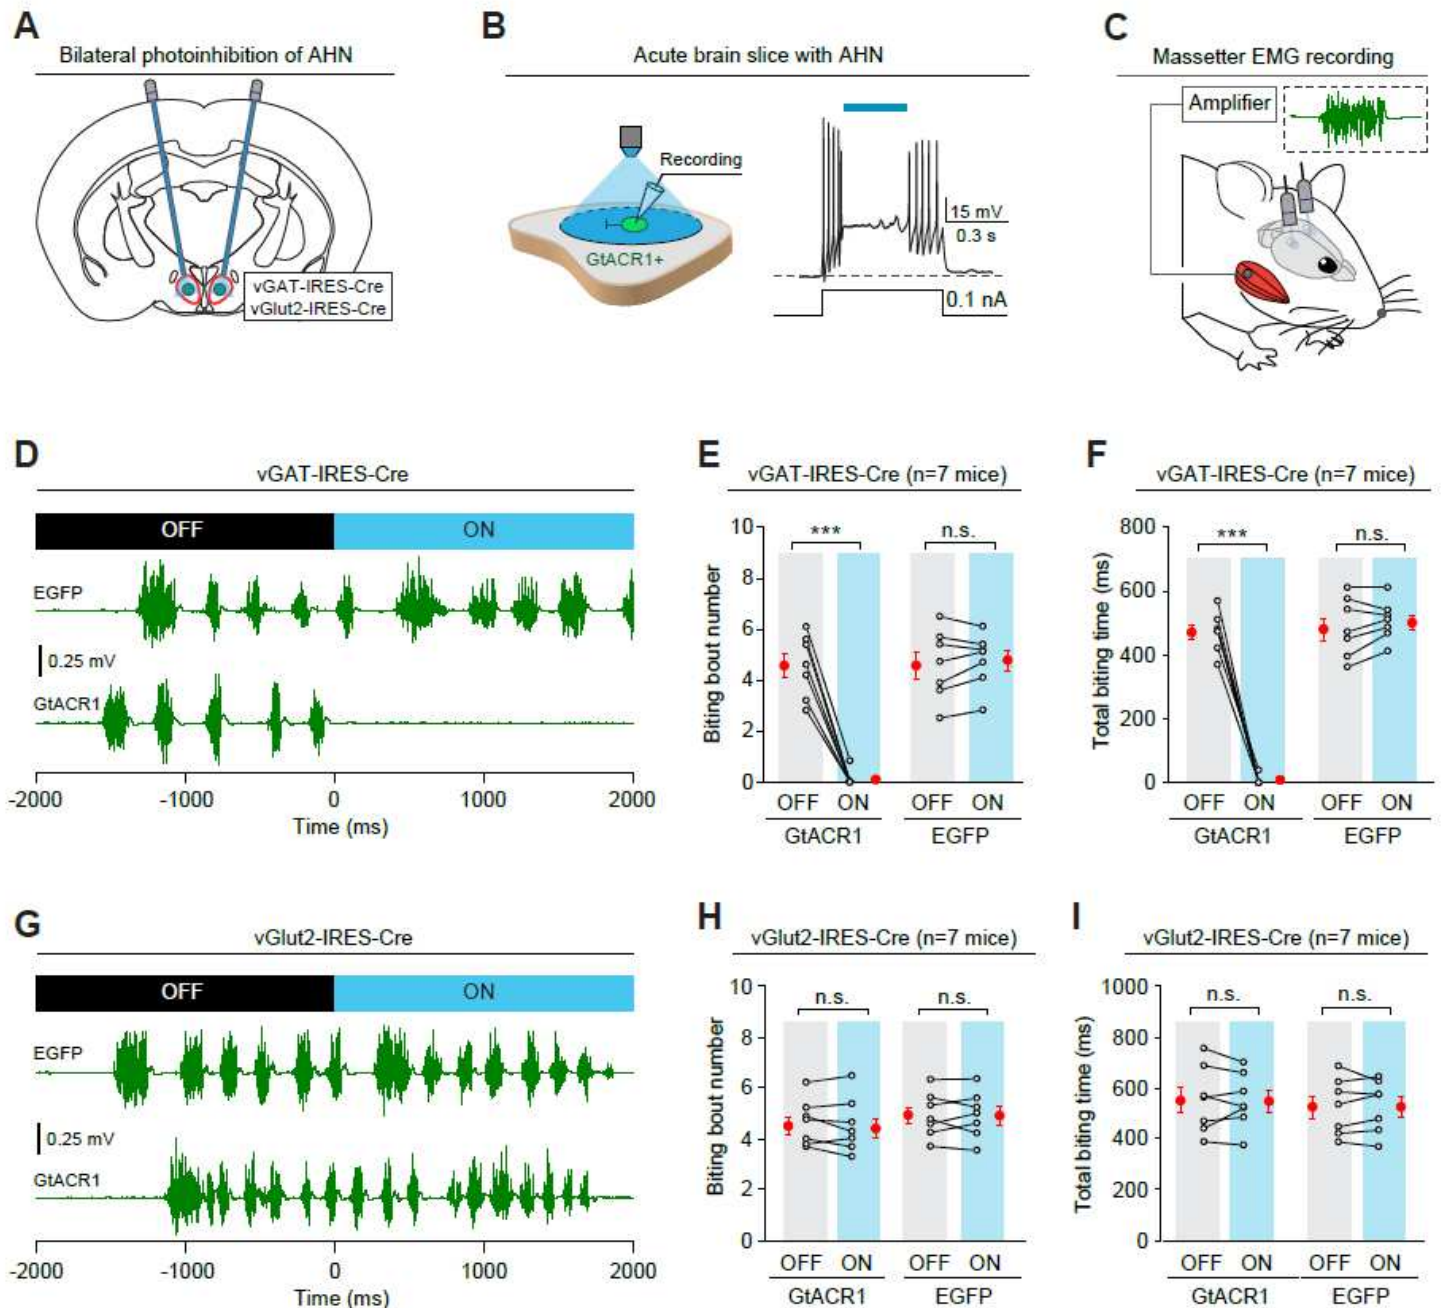

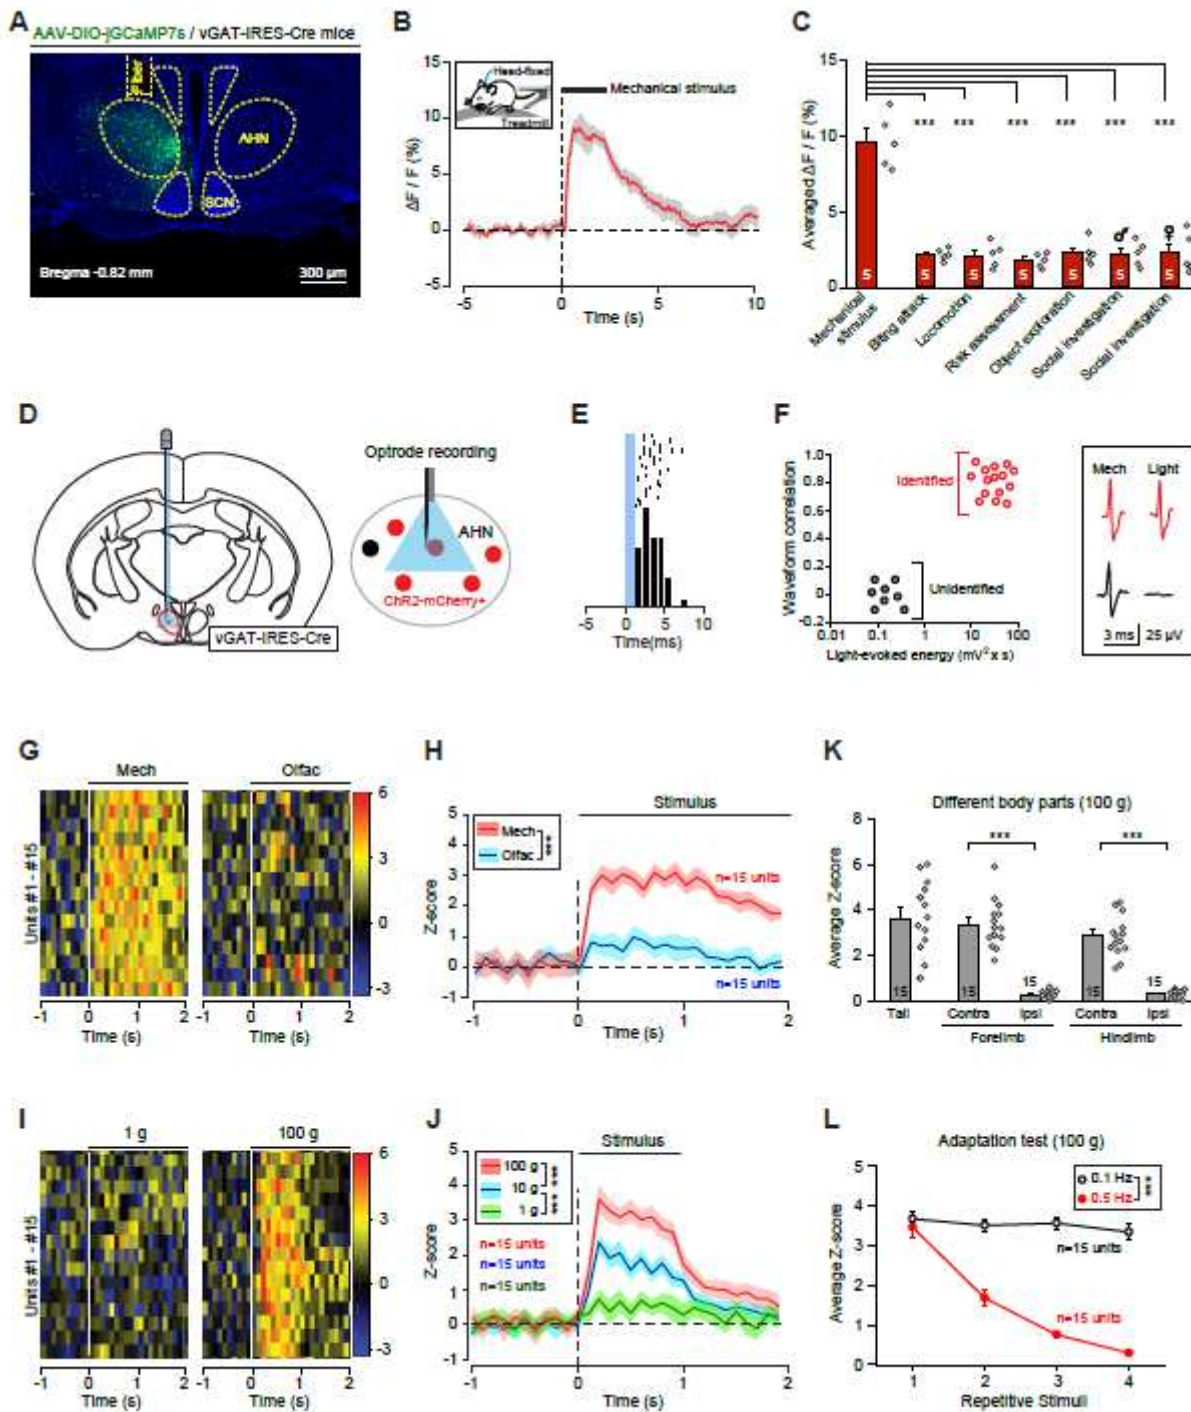

Figure 2

AHN vGAT+ neurons are required for mechanically-evoked defensive attack. (A) Schematic diagram of bilateral photoinhibition of AHN vGAT+ or vGlut2+ neurons. For the micrographs with the optic fiber tracks, see Figure S5A and S5B. For the analyses of cell-type specificity, see Figure S5C-S5F. (B) Schematic diagram (left) and example trace (right) showing photoinhibition of AHN neurons expressing GtACR1. (C) Schematic diagram showing EMG recording from masseter muscles of mice. (D-F) Example traces (D) and quantitative analyses of biting bout number (E) and total biting time (F) within laser OFF phase and ON phase, showing the effect of photoinhibition of vGAT+ AHN neurons on mechanically-evoked biting attack. Mice with EGFP expressed in AHN vGAT+ neurons were used as a control for GtACR1. (G-I) Example traces (G) and quantitative analyses of biting bout number (H) and total biting time (I) within phases of laser OFF and ON, showing the effect of photoinhibition of AHN vGlut2+ neurons on mechanically-evoked biting attack. Mice with EGFP expressed in AHN vGlut2+ neurons were used as a control for GtACR1. For the effect of photoinhibition of AHN vGAT+ neurons on locomotion speed of freely-moving mice, see Figure S5H. Number of mice was indicated in the graphs (E, F, H, I). Data in (E, F, H, I) are means ± SEM (error bars). Statistical analyses in (E, F, H, I) were performed by Student t-tests (n.s. $P > 0.1$, *** $P < 0.001$). For the P values, see Table S4.
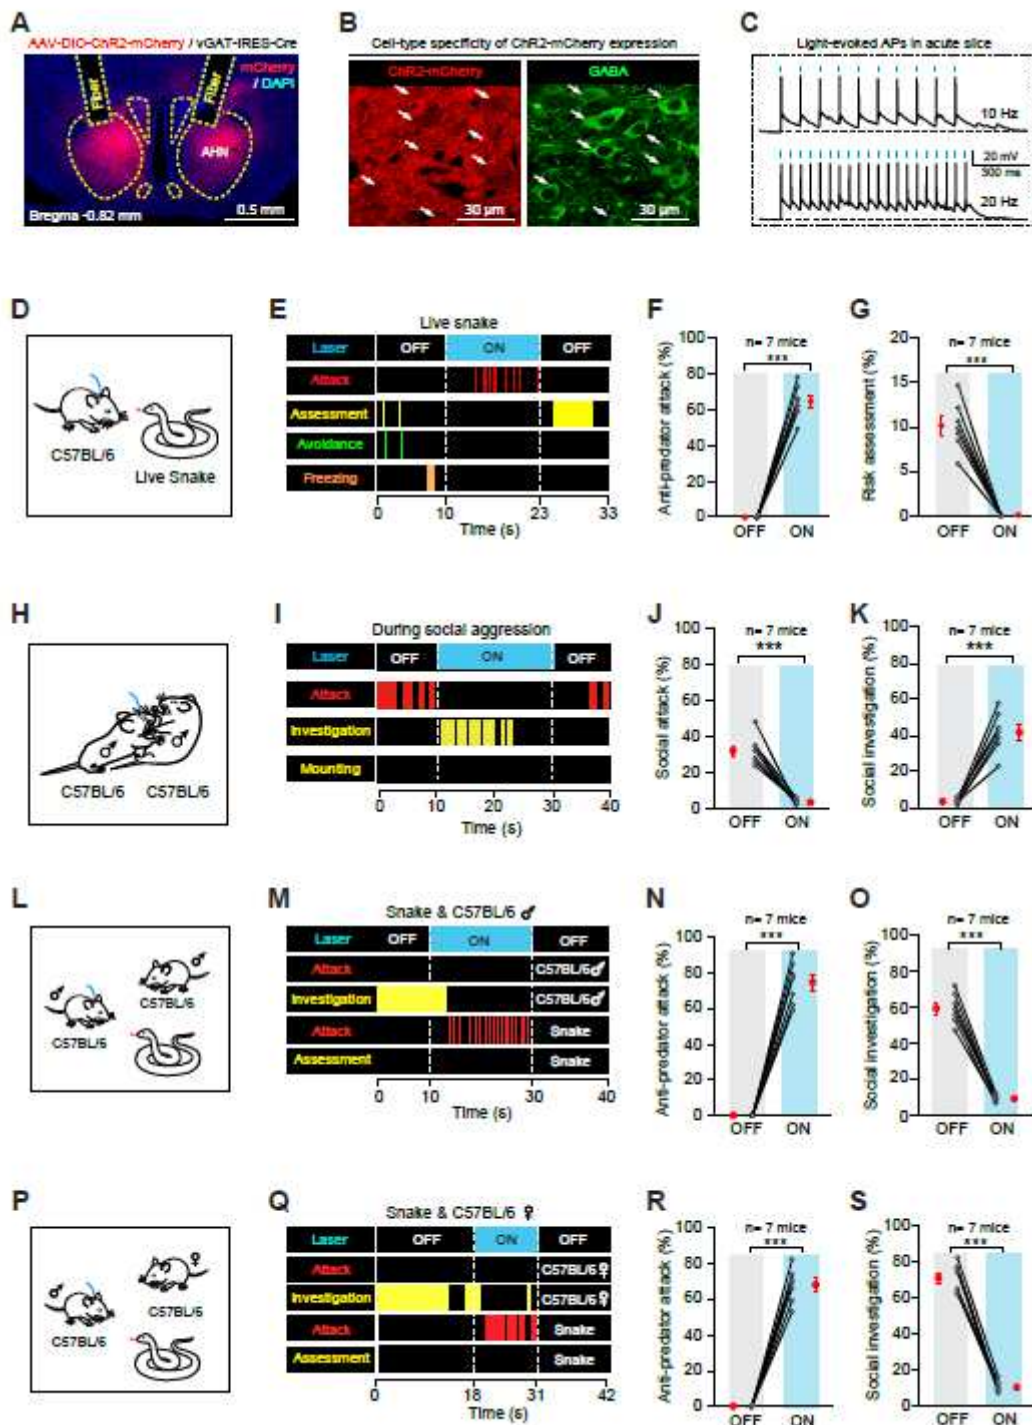

Figure 3

AHN vGAT+ neurons encode mechanical stimuli. (A) An example micrograph showing jGCaMP7s expressed in the AHN of vGAT-IRES-Cre mice and the optical fiber track above the AHN. For the analyses of cell-type specificity of jGCaMP7s expression, see Figure S6A and S6B. (B) Normalized GCaMP fluorescence changes (ΔF/F) in response to noxious mechanical stimulus on the tail. Inset, the head-fixed awake mouse standing on a treadmill was applied with noxious mechanical stimulus by tail clamping with an alligator-clip. (C) Quantitative analyses of peak GCaMP responses of AHN vGAT+ neurons in
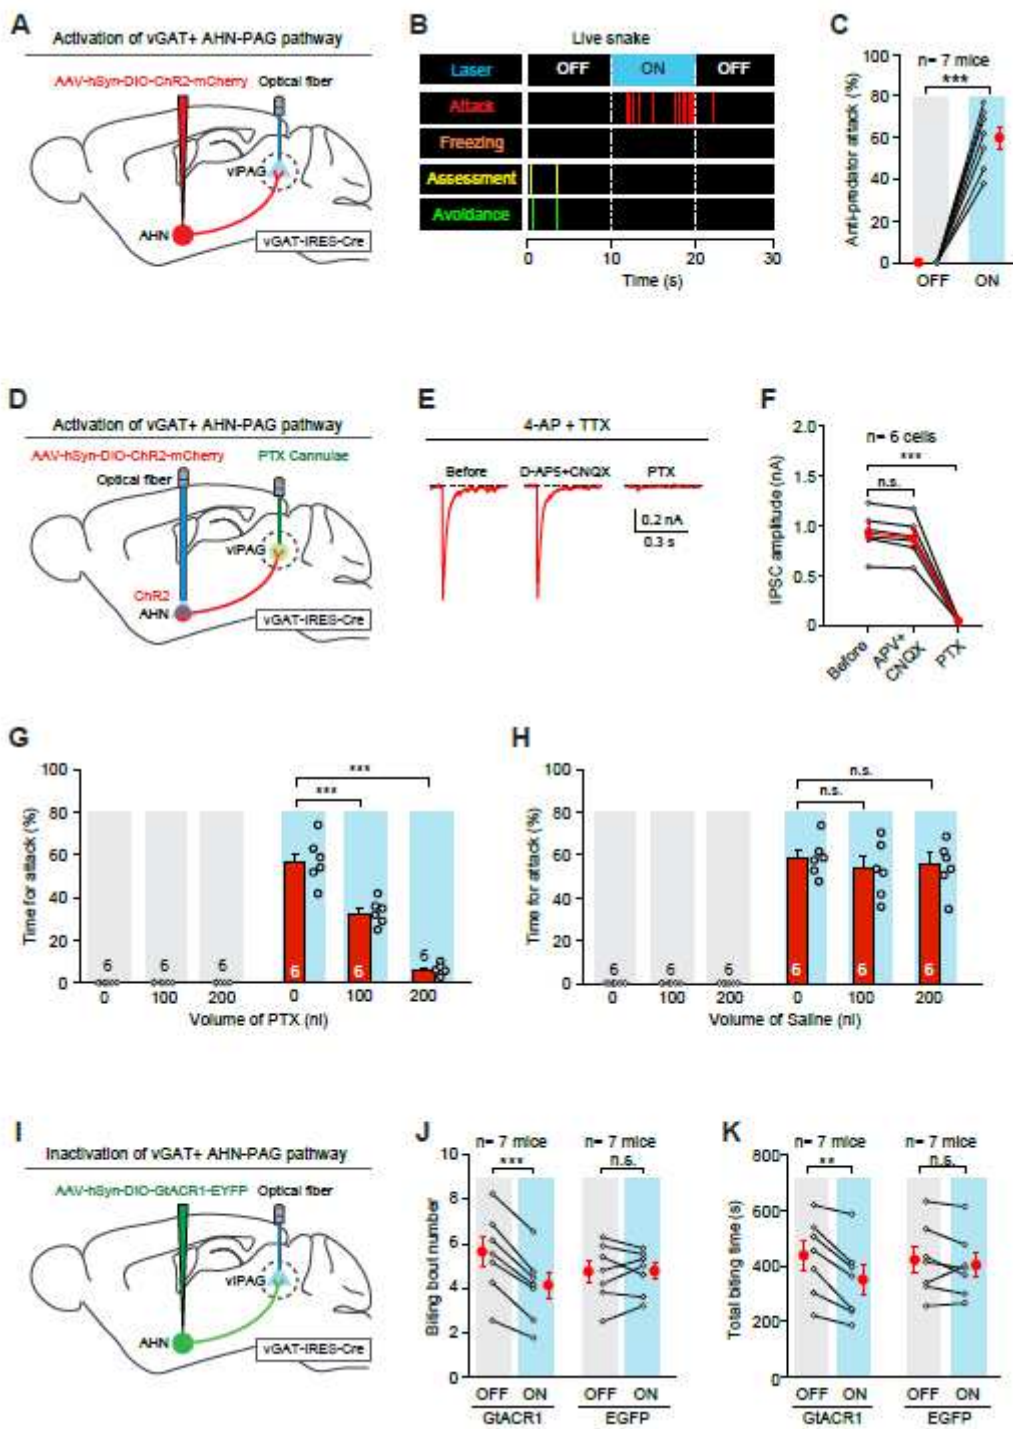

seven behavioral tests. The example trace for the test of "Mechanical stimulus" was in Figure 3B, while the other six example traces were in Figure S6C-S6H. (D) Schematic diagram of optrode recording from AHN vGAT+ neurons expressing ChR2-mCherry. For an example micrograph showing the optical fiber track and electrolytic lesion of recording site in the AHN, see Figure S7A. The principal component analysis for spike sorting of an example unit was in Figure S7B. (E) Raster and peri-stimulus time histogram (PSTH) of an example putative AHN vGAT+ neuron with spiking latency less than 5 ms relative to the onset of light pulses. (F) Correlation analysis of action potentials of individual units evoked either by light pulses (Light) or by mechanical stimuli (Mech), confirming a segregation between optogenetically identified units (Identified, red) and unidentified units (Unidentified, grey). (G) Heat-map PSTH of Z-scored firing rates of individual AHN vGAT+ neurons to mechanical stimuli (Mech) or olfactory stimuli (Olfac). For the schematic diagrams showing the application of mechanical stimuli and olfactory stimuli to the test mice, see Figure S7C and S7E. For the example units of putative AHN vGAT+ neurons in response to mechanical stimuli and olfactory stimuli, see Figure S7D and S7F. (H) Average PSTH of Z-scored firing rates of all identified AHN vGAT+ neurons to mechanical stimuli (Mech, red) and olfactory stimuli (Olfac, blue). (I) Heat-map PSTH of Z-scored firing rates of individual AHN vGAT+ neurons to mechanical stimuli applied with von Frey filaments (1 g, 100 g). For the schematic diagram showing the application of von Frey filaments to the test mice, see Figure S7G. For the heat-map PSTH of Z-scored firing rates of individual AHN vGAT+ neurons to 10 g mechanical stimuli, see Figure S7H. (J) Average PSTH of Z-scored firing rates of all identified AHN vGAT+ neurons to mechanical force with different intensities. (K) Averaged peak Z-scored firing rates of all identified AHN vGAT+ neurons to mechanical stimuli (100 g) on different body parts. (L) Averaged peak Z-scored firing rates of all identified AHN vGAT+ neurons to four repetitive mechanical stimuli (100 g) applied at 0.1 Hz and 0.5 Hz on the tail. Number of mice (C) and number of units (H, J, K, L) were indicated in the graphs. Data in (B, C, H, J, K, L) are means ± SEM (error bars). Statistical analyses were performed by Student t-tests (C, K) and One-Way ANOVA (H, J, L) (*** $P <$ 0.001). For the P values, see Table S4.

Figure 4

Activation of AHN vGAT+ neurons trigger biting attack to non-social targets. (A) An example coronal section showing ChR2-mCherry expression in the AHN of vGAT-IRES-Cre mice and bilateral optical fiber tracks above the AHN. (B) Example micrographs showing the cell-type specificity of ChR2-mCherry expression in GABA+ AHN neurons. Arrows indicated soma of GABA+ cells expressing ChR2-mCherry. For the quantitative analysis, see Figure S9A. (C) Light-pulse trains (473 nm, 2 ms, 10 mW, 10 Hz or 20 Hz) reliably evoked phase-locked spiking activity in ChR2-mCherry+ AHN cells. (D) Schematic diagram

showing a test mouse confronted with a live snake in the arena. (E-G) Example behavioral ethogram (E), quantitative analyses of time for anti-predator attack (F) and time for risk assessment (G) of mice before (OFF) and during (ON) photostimulation of AHN vGAT+ neurons. For quantitative analyses of time for freezing and avoidance, see Figure S9B and S9C. The colored bars in the ethograms indicated the onset and offset of specific behaviors. (H) Schematic diagram showing a test mouse exhibiting social aggression toward a male intruder. (I-K) Example behavioral ethogram (I), quantitative analyses of time for social attack (J) and time for social investigation (K) of mice before (OFF) and during (ON) photostimulation of AHN vGAT+ neurons. For more behavioral analyses, see Figure S10. (L) Schematic diagram showing a test mouse confronted with a live snake and a male C57BL/6 mouse in the arena. (M-O) Example behavioral ethogram (M), quantitative analyses of time for anti-predator attack (N) and time for social investigation (O) of test mice before (OFF) and during (ON) photostimulation of AHN vGAT+ neurons. For more behavioral analyses, see Figure S11 A-S11D. (P) Schematic diagram showing a test mouse confronted with a live snake and a female C57BL/6 mouse in the arena. (Q-S) Example behavioral ethogram (Q), quantitative analyses of time for anti-predator attack (R) and time for social investigation (S) of test mice before (OFF) and during (ON) photostimulation of AHN vGAT+ neurons. For more behavioral analyses, see Figure S11E-S11H. Number of mice was indicated in the graphs (F, G, J, K, N, O, R, S). Data in (F, G, J, K, N, O, R, S) are means ± SEM (error bars). Statistical analyses in (F, G, J, K, N, O, R, S) were performed by Student t-tests (*** P < 0.001). For the P values, see Table S4.

Figure 5

Role of vGAT+ AHN-PAG pathway 595 for mechanically-evoked defensive attack. (A) Schematic diagram showing AAV injection and optic fiber implantation for light stimulation of vGAT+ AHN-vlPAG pathway. For the example micrographs of the AHN and vlPAG, see Figure S13, A and B. (B, C) Example behavioral ethogram (B) and quantitative analysis of time for anti-predator attack (C) of mice before (OFF) and during (ON) activation of vGAT+ AHN-PAG pathway. For more behavioral analyses, see Figure S13C-S13E. For the analyses of vGAT+ AHN-LS pathway, see Figure S14. The colored bars in the ethograms indicated

the onset and offset of specific behaviors. (D) Schematic diagram showing AAV injection into the AHN, optical fiber implantation above the AHN, and cannulae implantation above the vlPAG in vGAT-IRES-Cre mice. For the example micrographs with the optic fiber track and cannulae track above the AHN and vlPAG, see Figure S15A and S15B. (E, F) Example traces of postsynaptic currents (PSCs) recorded from vlPAG neurons (E) and quantitative analyses of their amplitude (F) showing the GABAergic action of vGAT+ AHN-PAG pathway is mediated by GABAa receptor. For the schematic diagram for slice physiology, see Figure S15C. (G, H) Quantitative analyses of light-evoked biting attack to live snake in mice with vlPAG treated with different doses of PTX (G) or saline (H). For the example behavioral ethograms, see Figure S15E and S15F. (I) Schematic diagram showing AAV injection and optic fiber implantation for photoinhibition of vGAT+ AHN-vlPAG pathway. For example micrographs of the AHN and vlPAG, see Figure S16A and S16B. (J, K) Quantitative analyses of biting bout number (J) and total biting time (K) toward dummy snake within phases of laser OFF and ON, showing the effect of photoinhibition of vGAT+ AHN-vlPAG pathway on mechanically-evoked biting attack. Mice with EGFP expressed in AHN vGAT+ neurons were used as a control for GtACR1. For example traces, see Figure S16C. Number of mice (C, G, H, J, K) and cells (F) were indicated in the graphs. Data in (C, F, G, H, J, K) are means ± SEM (error bars). Statistical analyses in (C, F, G, H, J, K) were performed by Student t-tests (n.s. $P > 0.1$; ** $P < 0.01$; *** $P < 0.001$). For the P values, see Table S4.
