Abstract

Purpose: To testify whether multi-b-values DWI can be used to ultra-early predict treatment response of CCRT in cervical cancer patients and to assess the predictive ability of concerning parameters. **Methods:** 53 patients with biopsy proved cervical cancer were retrospectively recruited in this study. All patients underwent pelvic multi-b-values DWI before and at the 3rd day during treatment. Tumor diffusion parameters were calculated by mono-exponential (apparent diffusion coefficient, ADC), bi-exponential (D_{slow} , D_{fast} and f_p) and stretched exponential (distributed diffusion coefficient, DDC and α) models. Treatment response was assessed based on RECIST v1.1 at 1 month after the completion of whole CCRT. Parameters were compared using independent t test or Mann-Whitney U test as appropriate. Receiver operating characteristic (ROC) curves was used for statistical evaluations. **Results:** ADC-T0 ($p=0.02$), D_{slow} -T0 ($p<0.01$), DDC-T0 ($p=0.03$), ADC-T1 ($p<0.01$), D_{slow} -T1 ($p<0.01$), ΔADC ($p=0.04$) and $\Delta\alpha$ ($p<0.01$) were significant lower in non-CR group patients. ROC analyses showed that ADC-T1 and $\Delta\alpha$ exhibited high prediction value, with area under the curves of 0.880 and 0.869, respectively. **Conclusion:** Multi-b-values DWI can be used as a noninvasive technique to assess and predict treatment response in cervical cancer patients at the 3rd day of CCRT. ADC-T1 and $\Delta\alpha$ can be used to differentiate good responders from poor responders.

Introduction

Diffusion-weighted imaging (DWI) is sensitive to water molecular diffusion within biological tissues. Apparent diffusion coefficient (ADC) derived from mono-exponential model (MEM) is still the most adopted parameter in guiding daily clinical work nowadays. The ADC values may not reflect water diffusion in tissue accurately, because it is also influenced by the microcirculation perfusion in capillaries [1]. Based on bi-exponential model (BEM), multi-b-values DWI might enable to separate the microcirculation perfusion from true diffusion [1-2]. Stretched exponential model (SEM) offers information on heterogeneity of intravoxel diffusion rates and the distributed diffusion effect, thus providing complementary information of tissue property [3]. MEM, BEM and SEM DWI models have already been applied as imaging biomarker to predict and assess treatment response in rectal cancer, head and neck squamous cell carcinoma, breast cancer, prostate cancer and esophageal squamous cell carcinoma [4-15]. Several reports revealed that MEM, BEM and SEM DWI models could be used in the diagnosis, differentiation and separation of type and grade in cervical cancer (CC) [16, 17]. BEM DWI models were useful for predicting and monitoring the treatment efficacy CC patients [18-20], but results were contradictory. To date, SEM DWI models has not been used in the prediction and assessment of treatment response in CC.

It is generally agreed that tumor volume diminish is a favorable indicator of good treatment response [21, 22] and volume reduction is related with local control in CC patients underwent concurrent chemoradiotherapy (CCRT) [23]. Currently researches concerning treatment response prediction mainly focus on parameters change at 1 week and 4 weeks after treatment initiation [19, 20, 24], but no earlier time-

points have been evaluated. With the increase of chemoradiotherapy dose, toxicity and adverse side effects aggravate in CC patients during CCRT. Therefore, it is valuable to search an ultra-early time-point to evaluate the treatment response. Tumor molecular changes generally happen earlier than morphological change during CCRT in CC. In order to search an earlier time-point to identify good responders from poor responders, we set the completion of third external beam radiotherapy (EBRT) (at a dose of 6 Gy) as ultra-early monitoring point by using multi-b-values DWI. In order to investigate tumor diffusion property change accurately during CCRT between good and poor responders, mono-exponential, bi-exponential, and stretched exponential DWI models were performed.

The present study aimed to search for a potential early imaging biomarker to predict treatment response of CCRT in CC patients at early stage by using multi-b-values DWI parameters.

Materials And Methods

Patients

This study was approved by the ethics committee of Institutional Review Board of our hospital. Between Nov 2018 and May 2019, 53 consecutive patients with histologically proven untreated CC scheduled to undergo CCRT treatment were enrolled in this retrospective study. The exclusion criteria were contradictions for MR scanning or CCRT. There was no dropout in our research.

CCRT treatment

All patients were treated with a combination of EBRT and intracavitary brachytherapy (ICBT). EBRT was delivered to the whole pelvis, with a total dose of 50 Gy (daily dose of 2 Gy, 5 times per week) and accompanied by concurrent chemotherapy: six cycles of weekly cisplatin (40 mg/m²) or three cycles of cisplatin (75 mg/m²) at 3-week intervals. ICBT was initiated after an EBRT dose of 46-50 Gy. ICBT was delivered once or twice a week in 4-5 fractions, with a fractional dose of 6-7 Gy at point A. The median dose of ICBT was 28 Gy and the median biological effective dose (BED) was 47.8 Gy (range, 23.3-64.7 Gy) to point A.

MRI protocol

All patients underwent MR examination at two time-points: within 1 week before (T₀) and the 3rd day during (T₁) CCRT. All MR examinations were performed on a 3.0 T MRI scanner (GE Healthcare 750 Discovery, Milwaukee, Wisconsin, USA) using an 8-channel phase array coil. Routine MRI protocols included sagittal T₂WI (repetition time [TR]/echo time [TE]: 4,763 /85 ms; slice thickness/spacing: 4 /0.4 mm; field of view [FOV]: 28 cm; number of excitations [NEX]: 4), coronal T₂WI (TR/TE: 4171 /85 ms; slice thickness/spacing: 5 / 0.5 mm; FOV: 32 cm; NEX: 4), axial T₂WI with fat suppression (TR/TE: 4580 /85 ms; slice thickness/spacing: 4 /1 mm; FOV: 34 cm; NEX: 4), axial T₁WI (TR/TE: 601 /minimum ms; slice

thickness/spacing: 3 /1 mm; FOV: 32 cm; NEX: 2). Axial multi-b-values DWI with 11 b-values of 0, 10, 20, 40, 80, 150, 200, 400, 800, 1000 and 1200 s/mm² was performed with a single-shot echo-planar sequence (TR/TE: 3883 /59 ms; slice thickness/spacing: 5 /0.5 mm; FOV: 36 cm; matrix, 128×160; NEX 1 to 6 with the increasing of b-values, total scan time 6:34 min).

Treatment response assessment

Treatment response was assessed at one month after the completion of the entire CCRT by using convention MR scanning according to the evaluation criteria in solid tumors (RECIST v1.1^[25]) as follows: (1) complete response (CR): no residual tumor showed on the MR images; (2) partial response (PR): the largest diameter of residual tumor was at least 30% less than the original size; (3) progressive disease (PD): there was an at least 20% increase in the longest diameter of tumor compared with the pretreatment size; (4) stable disease (SD): there was neither a decrease sufficient to qualify for PR nor an increase sufficient to qualify for PD. All patients were dichotomized into two groups, CR group and non-CR group. The CR group consisted of patients with CR, while non-CR group consisted of patients with PR, SD and PD.

Image analysis

Two radiologists with 15 and 2 years' experience in gynecologic imaging performed post-process and image analysis independently. Readers were blinded to the pathological findings and therapeutic responses. All functional parameters maps were post-processed by using the MADC program on the Advantage Workstation (AW 4.6 version, GE, US). The regions of interest (ROIs) containing all the tumor region and avoiding obvious necrotic areas were manually delineated along the margin of tumor on the three consecutive maximal tumor slices on axial DWI images with b=1000 s/mm². The mean value of parameters of the three ROIs was used for statistical analysis.

The mono-exponential model was applied to calculate ADC value from all 11 b values by using the following equation ^[1]:

$$S/S_0 = \exp(-b \cdot \text{ADC}) \quad (1)$$

Where S_0 and S represent the signal intensity obtained with the $b=0$ and $b>0$ s/mm².

The bi-exponential model, also called intravoxel incoherent motion (IVIM), was applied to calculate D_{slow} , D_{fast} , and f_p values with the following equation ^[26]:

$$S_b/S_0 = (1-f_p) \cdot \exp(-b \cdot D_{\text{slow}}) + f_p \cdot \exp(-b \cdot D_{\text{fast}}) \quad (2)$$

Where S_b represents the mean signal intensity with diffusion gradient b , and S_0 represents the mean signal intensity at $b=0$ s/mm². The f_p (perfusion fraction) represents the ratio of water movement within capillaries compared with the total volume of water in a voxel. D_{slow} (pure diffusion coefficient) represents pure molecular diffusion where a physiological perfusion effect is excluded. D_{fast} (pseudo-diffusion coefficient) represents the average blood velocity and mean capillary segment length. Considering that D_{fast} is much greater than D_{slow} with one order of magnitude, the effects of D_{fast} on the signal decay at large b -values (>200 s/mm²) can be ignored.

The stretched exponential model was used to calculate DDC and α by using the following equation [3]:

$$S/S_0 = \exp(-(b \cdot DDC)^\alpha) \quad (3)$$

Where S_0 and S represents the signal intensity obtained with the $b=0$ and $b>0$ s/mm². DDC represents the distributed diffusion coefficient reflecting the mean intravoxel diffusion rate, while α represents intravoxel diffusion heterogeneity index corresponding to intravoxel water molecular diffusion heterogeneity with a range from 0 to 1 [27].

Statistical analysis

All statistical analyses were performed using SPSS (Version 17.0, SPSS Inc., Chicago, IL, USA) and GraphPad Prism 5 (GraphPad Prism Software Inc., San Diego, California, USA). An intra-class correlation coefficient (ICC) was calculated to evaluate interobserver reliability of the measurements. Change of MRI parameters (Δ) was defined as $|\text{parameter-T1} - \text{parameter-T0}|$. All quantitative values are presented as the mean \pm standard deviation (SD). Clinical characteristics of cervical cancer patients with different treatment outcome was compared using Chi-square test. The Kolmogorov–Smirnov test was conducted to analyze the normal distribution of all metrics. Comparisons between CR group and non-CR group, and between different time-points were performed by using independent t test (D_{slow} , DDC and α , which conformed to normal distribution) and Mann–Whitney U test (ADC, D_{fast} and f_p , which did not conform to normal distribution). Two-tailed p values were used and p values less than 0.05 were considered as statistically significant. The area under the curve (AUC) of the receiver operating characteristic (ROC) curves for the significant parameters were calculated and compared. The cut-off values were selected by using the maximized values of the Youden indexes. The values that corresponded to the highest Youden index were chosen as the optimal threshold values.

Results

Patients and Treatment Characteristics

Patients and treatment characteristics were listed in Table 1. The final study cohort included 53 CC patients with FIGO II-IVB disease (mean age: 51.2 years, range 27–67 years). One month after the

completion of CCRT, MRI examination showed that 35 of the 53 patients (66.04%) achieved CR and 18 patients (33.96%) achieved incomplete response. No significant differences were observed between patient groups in terms of clinical characteristics. Figures 2 and 3 provided functional parameter maps of CR and non-CR patients before and during CCRT.

Table 1

Clinical characteristics between cervical cancer patients with different treatment outcome.

Clinical characteristics	CR	non-CR	t or χ^2	p

Interobserver agreement in imaging analysis

The intraclass correlation coefficients (ICCs) of all parameters were ranging between 0.852 to 0.934, which means the measurements of MEM, BEM and SEM derived parameters had good interobserver reproducibility. Details were presented in Table 2.

Table 2
Interobserver consistency of DWI derived parameters.

	ICC	95% confidence interval
ADC ($\times 10^{-3}$ mm ² /s)	0.934	0.913–0.958

Comparison of MRI parameters between CR group and non-CR group

The differences of ADC, D_{slow}, D_{fast}, f_p, DDC and α values between patients with different clinical outcome were presented in Table 3. Our results revealed that pretreatment ADC-T0 (0.94×10^{-3} vs 1.08×10^{-3} mm²/s, p = 0.02), D_{slow}-T0 (0.76×10^{-3} vs 0.93×10^{-3} mm²/s, p < 0.01) and DDC-T0 (1.02×10^{-3} vs 1.20×10^{-3} mm²/s, p = 0.02) was significantly lower in non-CR group patients. At the 3rd day during CCRT, ADC-T1 (1.26×10^{-3} vs 1.00×10^{-3} mm²/s, p < 0.01) and D_{slow}-T1 (1.07×10^{-3} vs 0.92×10^{-3} mm²/s, p < 0.01) were significantly higher in CR group patients. Between the two time-points, the changes of ADC (Δ ADC: 0.18×10^{-3} vs 0.05×10^{-3} mm²/s, p = 0.04) and α (Δ α : 0.03 vs 0.01, p < 0.01) were significantly bigger in CR group patients. No significant differences were found in D_{fast}-T0, D_{fast}-T1, Δ D_{fast}, f_p-T0, f_p-T1, Δ f_p, DDC-T1, Δ DDC, α -T0 and α -T1 between the two groups (p > 0.05).

ROC analysis of MRI parameters

The results of ROC analyses of DWI-derived parameters were presented in Table 4 and Fig. 1. The ROC analysis indicated that ADC-T1 showed the highest predictive value, with an AUC of 0.880, closely followed by $\Delta\alpha$ (AUC = 0.869). The predictive values of ADC-T0, Δ ADC, D-T0, D-T1 and DDC-T0 were low, with AUCs below 0.80. By adopting these parameters into treatment response prediction, ADC-T1 showed high predictive sensitivity of 83.78%, specificity of 75.00%, positive predictive value of 88.57% and negative predictive value of 66.67%, while $\Delta\alpha$ showed high predictive sensitivity of 90.91%, specificity of 75.00%, positive predictive value of 85.71% and negative predictive value of 83.33%.

Table 4

Sensitivity, specificity, PPV, and NPV of parameters at optimal cutoff values for differentiate patients with different treatment outcomes.

Parameters	AUC (95%CI)	Optimal cutoff value	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
ADC-T0	0.699(0.551–0.847)	0.995($\times 10^{-3}$ mm ² /s)	82.14	52.00	65.71	72.22
ADC-T1	0.880(0.786–0.975)	1.050($\times 10^{-3}$ mm ² /s)	83.78	75.00	88.57	66.67

$\Delta\alpha$	0.869(0.768–0.970)	0.022	90.91	75.00	85.71	83.33

Note: AUC = area under the curve, PPV = positive predictive value, NPV = Negative predictive value.

Discussion

In present study, we applied multi-b-values DWI derived perfusion and diffusion parameters for ultra-early prediction of treatment response to CCRT in CC patients. The present study revealed the different perfusion and diffusion characteristics between CR and non-CR group patients on the basis of MEM, BEM and SEM DWI models. The results of this study showed that pretreatment diffusion parameters including

ADC-T0, D_{slow} -T0, and DDC-T0 were significantly higher in CR group patients. Pretreatment CR group patients possess better water diffusion property than non-CR group patients, which may be due to relative loose cellularity or consistent distribution. This resulted in higher sensitivity to treatment regime in CR group patients. Better perfusion of the tumor helps delivery of cytotoxic drugs as well as oxygen during radiation therapy [10], but we didn't find difference between D_{fast} and f_p , this may be caused by the complexity of microcirculation perfusion.

Moreover, our study demonstrated that the completion of 3rd day can be a feasible time-point to monitor and predict treatment response. Baseline ADC, D_{slow} , DDC exhibited diagnostic ability, but diagnostic potency was higher for ADC-T1 and $\Delta\alpha$. By monitoring DWI parameters on 3rd day, we can raise accuracy in differentiating patients with different treatment response. Previous studies demonstrated that change of tumor diffusion property can be used as indicator to screen out poor responders in CC patients underwent CCRT [28, 29]. We further advanced the monitoring time-point to the completion of third EBRT, and found that MEM, BEM and SEM DWI derived parameters showed significant difference between good and poor responders. Long before morphological tumor volume reduction, an early increase in water molecular diffusivity may be associated with the reduced tumor cellularity and destructive cell membrane integrity due to apoptosis and necrosis during chemoradiation [10]. By adopting multi-b-values DWI, we can quantitatively measure therapeutic reaction non-invasively in vitro at ultra-early time-point with high accuracy. This may provide supplementary information for prompt and individualized interventions for poor responders to economize medical expenditure and alleviate unnecessary toxicity and complications [30].

Compared with MEM and SEM, BEM derived parameters showed larger fluctuation and poor repeatability. The results in several BEM based studies varied. Wang et al. reported that D_{slow} values were significantly higher for the responders than non-responders before and 3 weeks after neoadjuvant chemotherapy treatment (NACT) initiation in CC patients [18], which was in consistent with our research. However, Kato et al. reported that no significance was found before and during CRT at a dose of 20 Gy, but the changes of D_{slow} , D_{fast} and f_p between the two time-points were significantly higher in CR group patients [20]. Their study had smaller cohort population and only enrolled squamous cell carcinoma, hence might not be broadly representative. Moreover, they only used 6 b values to calculated BEM parameters, whereas previous studies used 10 or more b values to calculate BEM parameters in treatment response prediction, therefore this might cause bias in their research. We didn't find difference in D_{fast} and f_p before and during treatment between the two groups. During our research, we found that this might be caused by the poor repeatability and large fluctuation of D_{fast} . Che et.al also reported this phenomenon [12]. Andreou et al. declared that these could be due to intra tumoral heterogeneity and noise variation [6]. Further research should be conducted in order to illustrate this fluctuation. The f_p showed good repeatability but we didn't find difference between the two groups. The mechanism for an increase in f_p is uncertain, but may reflect vascular normalization within tumors [13].

Unlike BEM, SEM was reported to show high precision and excellent repeatability, which was an important consideration when evaluating diffusion models for treatment response prediction [13, 14, 31]. The parameters obtained from SEM were highly repeatable, therefore they might be robust and could be employed as reliable quantitative tools. Our results also support this idea. SEM derived parameters have been used to assess and predict treatment response in brain, breast, rectal, prostate tumors [11, 14, 32, 33]. A very strong positive relationship between ADC, D_{slow} and DDC was found [13, 34]. This may indicate that they are sensitive to the same tissue characteristics and provide similar information. CR group CC patients with the higher DDC-T0 might be more sensitive to drugs within the microenvironment. Tumors with higher cellular and glandular pleomorphism tend to have higher level of intravoxel diffusion heterogeneity thus a lower α [14]. Zhu et al. reported that $\Delta\alpha$ was higher in patients achieved pathological complete response in locally advanced rectal cancer patients [5], which was consistent with our result. Several studies have shown that high-grade or high-stage tumors exhibited lower α values [27, 32], thereby the increase of α values could be interpreted as the tumor is less aggressive and more sensitive to treatment.

There were several limitations in this study. First, the regions of interest were selected in the maximal solid parts of the tumors instead of the entire tumors, which might lead to selection bias owing to histological heterogeneity of tumors. Second, the follow-up time was relatively short and longer follow-ups needed for further confirmation of our results. Third, more monitoring time-points should be set in order to observe the dynamic changes of parameters as some parameters fluctuate during treatment. Our results were preliminary conclusion and further investigation was going to be proceeded.

In conclusion, the 3rd day may be a critical ultra-early time-point to assess and predict treatment response. Multi-b-values DWI derived parameters ADC-T1 and $\Delta\alpha$ have great potential for ultra-early prediction of treatment response of CCRT in CC patients.

Figures

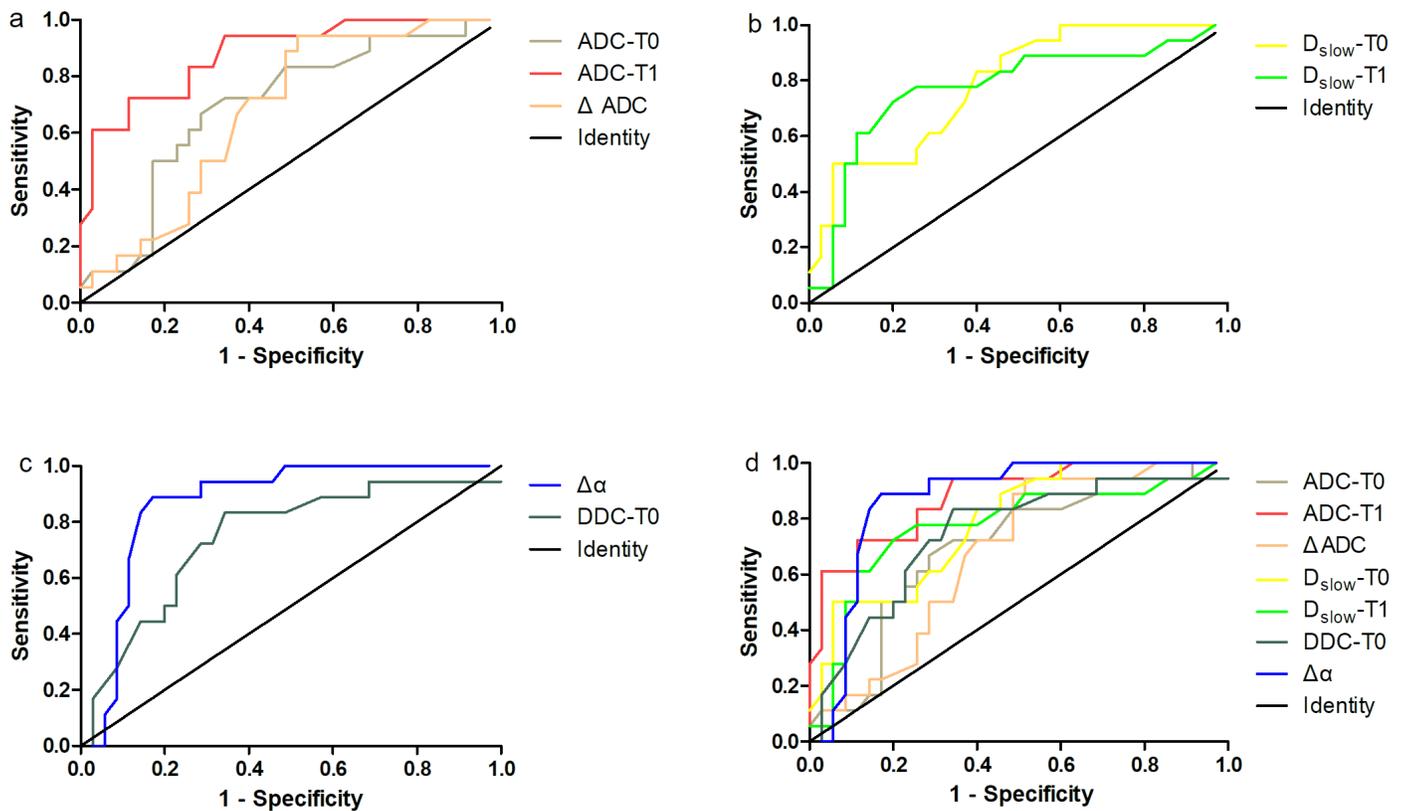

Figure 1

ROC curves of DWI derived parameters in differentiating the good responders from poor responders. (a) The AUCs of MEM derived parameters ADC-T0, ADC-T1 and Δ ADC were 0.699, 0.880 and 0.679, respectively. (b) The AUCs of BEM derived parameters D_{slow} -T0 and D_{slow} -T1 were 0.787 and 0.774. (c) The AUCs of SEM derived parameters $\Delta\alpha$ and DDC-T0 were 0.869 and 0.745. (d) ADC-T1 and $\Delta\alpha$ showed higher diagnostic accuracy with AUCs above 0.8 among DWI derived parameters. ROC = receiver operating characteristic curves, DWI = diffusion-weighted imaging, AUCs = areas under the curve.

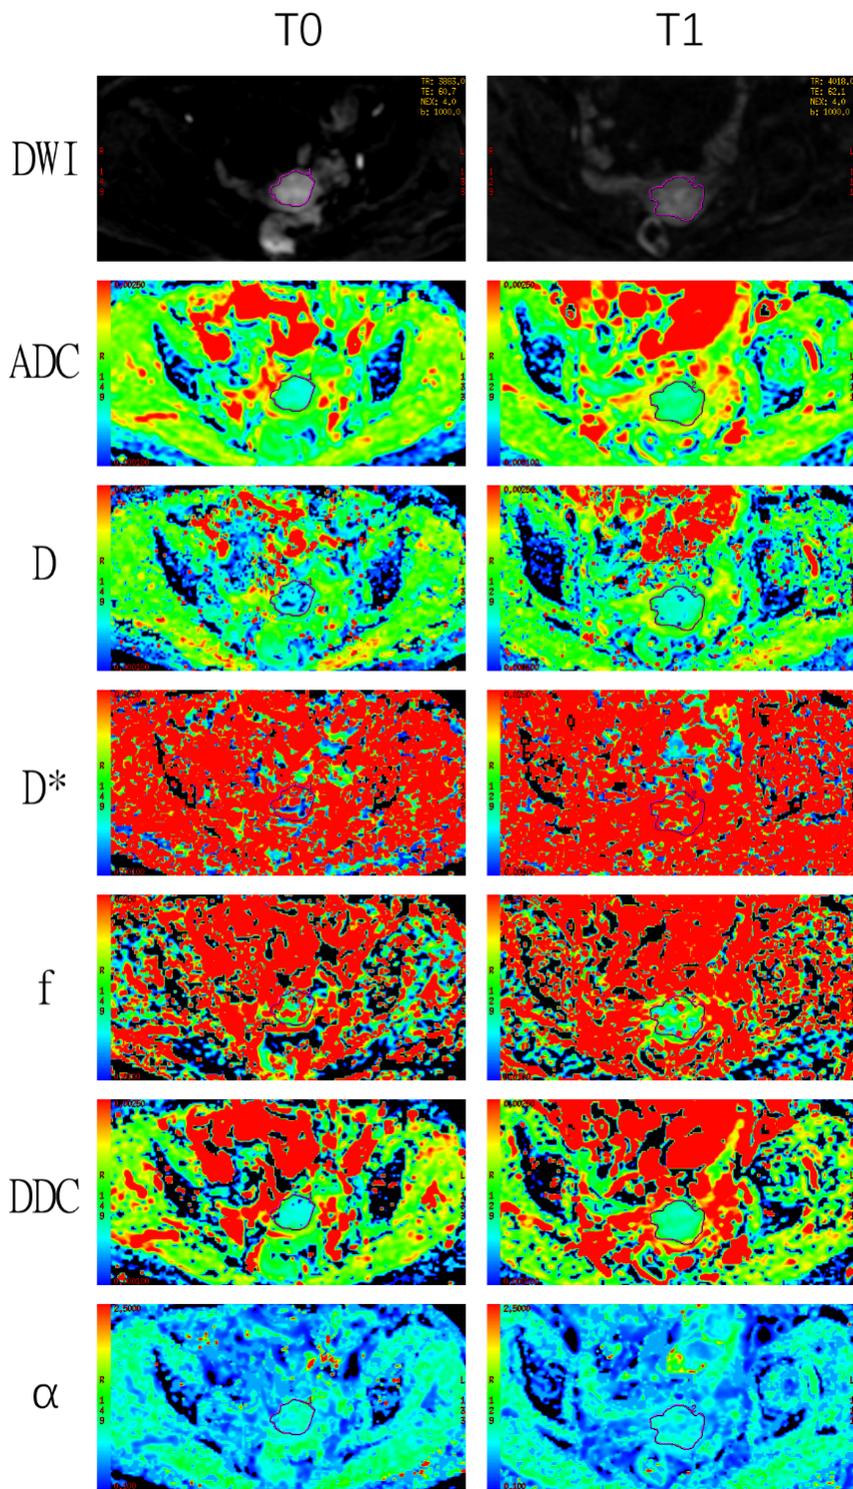

Figure 2

A 54-year-old woman with cervical cancer from the complete response group. Images in first line were DWI, ADC, Dslow, Dfast, fp, DDC and α maps at T0(before CCRT). The ADC, Dslow, Dfast, fp, DDC and α values were $0.97 \times 10^{-3} \text{ mm}^2/\text{s}$, $0.61 \times 10^{-3} \text{ mm}^2/\text{s}$, $99.02 \times 10^{-3} \text{ mm}^2/\text{s}$, 0.21, $0.92 \times 10^{-3} \text{ mm}^2/\text{s}$ and 0.76, respectively. Images in second line were DWI, ADC, D, D*, f, DDC and α at T1 (the 3rd day during CCRT) of

the same patient. The ADC, Dslow, Dfast, fp, DDC and α values were 1.71×10^{-3} mm²/s, 1.44×10^{-3} mm²/s, 81.82×10^{-3} mm²/s, 0.23, 2.53×10^{-3} mm²/s and 0.65, respectively.

Figure 3

A 56-year-old woman with cervical cancer from the non-CR group. Images in first line were DWI, ADC, Dslow, Dfast, fp, DDC and α maps at T0 (before CCRT). The ADC, Dslow, Dfast, fp, DDC and α values were 1.04×10^{-3} mm²/s, 0.90×10^{-3} mm²/s, 99.02×10^{-3} mm²/s, 0.15, 0.33×10^{-3} mm²/s and 0.70, respectively. Images in second line were DWI, ADC, D, D*, f, DDC and α at T1 (the 3rd day during CCRT) of the same patient. The ADC, Dslow, Dfast, fp, DDC and α values were 1.06×10^{-3} mm²/s, 0.81×10^{-3} mm²/s, 76.42×10^{-3} mm²/s, 0.22, 1.06×10^{-3} mm²/s and 0.76, respectively.
