Abstract

Introduction

Globally, Sierra Leone has some of the worst maternal and child health indicators. The situation is worsened by a dearth of evidence about the level of continuum of care, an evidence-based intervention aimed at reducing maternal and perinatal morbidity and mortality. Hence this study aimed to fill this gap in evidence in the level of and factors associated with continuum of maternal and newborn care.

Method

The study employed data from the 2019 Sierra Leone Demographic Health Survey (SLDHS). Analysis was restricted to women who had a live birth in the five years preceding the survey ($n = 7,326$). Bi-variable and multivariable logistic regression were performed using SPSS software version 25.

Results

Only 17.9% (95% CI: 17.4-19.1) of the women utilized complete continuum of care (CoC) for maternal and newborn health services in Sierra Leone. About 22% (95% CI: 21.3-23.1) utilized 8 or more antenatal care (ANC) contacts, 88% (95% CI: 87.9-89.4) had skilled birth attendance (SBA) while 90.7% (95% CI: 90.2-91.5) and 90.4% (95% CI: 89.9-91.2) of mothers and neonates utilized postnatal care (PNC) respectively. Having started ANC within first trimester (aOR 1.71, 95% CI: 1.46-2.00), belonging to the Southern region (aOR 1.85, 95% CI: 1.23-2.80), belonging to richer wealth quintile (aOR 1.76, 95% CI: 1.27-2.44), using internet (aOR 1.49, 95% CI: 1.12-1.98) and having no big problems seeking permission to access healthcare (aOR 1.34, 95% CI: 1.06-1.69) were significantly associated with utilization of CoC.

Conclusion

The overall completion of continuum of maternal care is low, with ANC being the lowest utilized component of continuum of care. The study findings further call for urgent attention for maternal health stakeholders to develop and implement tailored interventions prioritizing women empowerment, access to affordable internet services, timely initiation of ANC contacts, women in developed regions such as the Western and those from poor households.

Introduction

Globally, Maternal and child health (MCH) is still a key public health priority because many countries risk missing the sustainable development goal (SDG) 3 targets of reducing maternal mortality ratio (MMR) and neonatal mortality ratio (NMR) to less than 70 deaths per 100,000 live and 12 per 1,000 live births respectively by 2030 [1, 2]. Many countries across the globe continue to grapple with high maternal and perinatal mortality rates [3]. Estimates indicate that over 810 women die due to maternal related complications every day, with over 94% of these deaths occurring in low and middle income countries [4]. Sub-Saharan Africa alone accounts for approximately 67% of the maternal deaths with over 462 deaths

per 100,000 live births [5]. The estimated neonatal mortality rate indicates that 27.8 million children die globally in their first 28 days of life and still the highest rate remains in sub Saharan Africa [6].

Even within sub-Saharan Africa, major disparities exist, Sierra Leone not only remains one of the poorest countries, it also reports some of the highest maternal and child indicators [7–9]. For instance, the maternal mortality ratio (MMR) stands at 717 deaths per 100,000 live births, while the neonatal mortality ratio (NMR) is 31 deaths per 1,000 live births respectively [10, 11].

The World Health Organization has recommended a number of interventions and strategies to strengthen the continuum of care and these have been adopted by many countries including Sierra Leone [5, 14]. These include integrated and uninterrupted antenatal care (ANC), skilled birth attendance (SBA), and postnatal care (PNC) packages as critical strategies in reducing maternal and neonatal mortality and morbidity [1]. Timely ANC contacts are meant to effect birth preparedness, enable identification and treatment of illness during pregnancy [15]. Having skilled birth attendance from qualified and experienced professionals assures safe delivery with the necessary drugs and supplies for effective prevention, management of emergencies and also for referral in case of any obstetric complications [16, 17]. Overall, completion of the continuum of care follows a pathway from pregnancy to delivery to postpartum, where each step adds a value to ensure better health outcomes for mothers and newborns, and also contributes in maternal and neonatal mortality reduction [11, 13].

Optimal access to a complete of continuum of care has been proposed as a possible evidence-based intervention aimed at reducing preventable maternal and perinatal deaths [1]. The concept of maternal and newborn continuum of care is grounded in the assumption that well-being and health of women and newborns should be closely linked and managed in a unified way [12]. In addition to saving lives of mothers, completion of the continuum can save up to 160,000 newborn lives by maximizing ANC coverage, 390,000 additional newborn lives through high coverage of skilled childbirth care, and save 310,000 lives through postnatal care [13]. Early initiation and completion of the continuum could greatly help in solving challenges and improve the health and survival of women, newborns, and children worldwide [1].

However, studies across Africa continue to reveal very low completion rates for the continuum of care [1, 14, 15]. These low rates in the trends have been associated with socio-economic factors like educational status, residence, distance from the health facility, woman's decision making power, early initiation of ANC, wealth index, media access, skills of health workers, health system supports, and presence of delivery fees [5, 13, 16]. These continue to affect the continuity of the continuum and pose setbacks to the fight against maternal and neonatal mortality especially in low- and middle-income countries. Analysis of the level of completion of the continuum has proven an effective approach in understanding MCH trends for any particular country. Therefore, this study is aimed at assessing the level and determinants of completion of the continuum of care for maternal and newborn health in Sierra Leone, using data from the most recent national demographic health survey of 2019.

Methods

Study design and sampling methods

The Sierra Leone Demographic and Health Surveys (SLDHS) are cross-sectional surveys that are periodically conducted to obtain information on demographic, health and nutritional indicators of non-elderly adults and children. SLDHS was implemented by Statistics Sierra Leone (Stats SL) with technical assistance from ICF intern through the DHS Program and funded by the United States Agency for International Development (USAID). The latest survey was conducted over a four month period between 15th May 2019 and 31st August 2019 [10]. This national survey used stratified, two-stage cluster sampling design to obtain a representative sample of 13,872 households [10]. Weighted data was used to account for the unequal probability sampling in different strata. A detailed explanation of the sampling process is available elsewhere [10]. Women aged 15-49 years who were either permanent residents or visitors who had stayed in the selected households the night before the survey were eligible for interviews with a total of 15,574 women who were interviewed. Secondary analysis included women aged 15 to 49 years who had a live birth within five years preceding the survey (with the most recent birth being considered) and were either permanent residents or slept in the selected household the night preceding the survey. Out of the total weighted sample of 15,574 women in the data set, only 7,326 had given birth within five years preceding the survey (as shown in Table 1). Of the 7,326 women, 112 (1.5%) women had missing data on ANC initiation timing leading to a total of 7,214 women who were considered for logistic regression analysis (as shown in Table 3). The Demographic and Health Survey datasets are freely available to the public however researchers must first register with MEASURE DHS and then submit a request before accessing them. Written permission to access the whole ZDHS database was obtained through DHS program website [17].

Variables

Outcome variables

Complete continuum of maternal and newborn healthcare was the outcome variable and was constructed into a binary variable with complete coded as 1 and incomplete coded as 0. Complete continuum of maternal and newborn healthcare was considered when a woman reported having had all the three conditions/states:

1. Had at least eight ANC contacts during the most recent childbirth.
2. Skilled birth attendance
3. Mother and baby had at least one postnatal check-up within six weeks after childbirth [18, 19]

Independent variables

Eighteen independent variables were categorized into women and household characteristics, and were chosen basing on previous studies [20–22] and availability in the SLDHS database.

Household characteristics. Wealth index of household (categorized into quintiles: richest, richer, middle poorer and poorest), type of residence (urban and rural), and region that included the official five regions in the SLDHS (western, eastern, southern, northwestern and northern), household size (less than 7 and, 7 and above) and sex of household head (male and female) Wealth index is a measure of relative household economic status and was calculated by DHS from information on household asset ownership using principal component analysis [10, 23].

Women's characteristics. Age (15-24, 25-34, and 35-49 years), level of education (no education, primary, secondary, and tertiary), exposure to newspapers/magazines, internet, radio and TV (yes and no), parity (1, 2-4 and 5 and above), ANC initiation timing (first trimester and after first trimester), marital status (married and not married), working status (working and not working) and decision making for seeking healthcare (involved and not involved). Religion was categorized as Islam and Christianity and others while problems seeking permission and distance to health facility were categorized as big problem and no big problem. In the questionnaire, seeking permission to access healthcare and distance to health facility had three original responses: no problem, no big problem and big problem. However, none of the study participants reported no problem hence we only had two responses.

Statistical analysis

In order to account for the multi-stage cluster study design, complex sample package of SPSS (version 25.0) statistical software was used. Analysis was carried out based on the weighted count to account for the unequal probability sampling in different strata and to ensure representativeness of the survey results at the national and regional level.

Before multivariable logistic regression analysis, independent variables were assessed for their association with CoC utilisation using bivariable logistic regression analysis and we presented the crude odds ratio (cOR), 95% confidence interval (CI) and p-values. Independent variables associated with COC utilisation from literature and those with a p-value ≤ 0.25 at the bivariable level, and not strongly collinear (considered variance inflation factor less than 3) with other independent variables were considered for multivariable logistic regression to assess the independent effect of each variable on the CoC utilisation. Adjusted odds ratios (aOR), 95% confidence intervals (CI) and p-values were calculated with statistical significance level set at p-value < 0.05.

Results

A total of 7,326 women were included in the analysis (Table 1). Of these, 734 (10.0%) (95% CI: 9.6-11.0) had complete continuum of care (further details in Table 2). Majority of the women resided in rural areas (61.9%), had less than eight ANC contacts (78.0%), had had skilled birth attendance (88.3%), had a postnatal check after delivery (90.7%), belonged to Islam (78.7%), had no education (52.7%), resided in

male headed households (75.3%), were married (81.9%), working (77%) and aged between 20 and 34 years (65.9%). Most women had limited exposure to mass media with 57.7% of women not exposed to radio, 76.2% not exposed to TV, 89.9% not using internet and 94.5% not exposed to newspapers. The mean age and household size were 28.97 ± 7.25 years and 6.93 ± 3.45 members respectively.

Factors associated with CoC utilisation

After adjusting for other variables, factors that were significantly associated with COC utilisation were; having started ANC within first trimester (aOR 1.71, 95% CI: 1.46-2.00), belonging to the Southern region (aOR 1.85, 95% CI: 1.23-2.80), belonging to richer wealth quintile (aOR 1.76, 95% CI: 1.27-2.44), using internet (aOR 1.49, 95% CI: 1.12-1.98) and having no big problems seeking permission to access healthcare (aOR 1.34, 95% CI: 1.06-1.69).

Discussion

This study focused on the level of CoC in Sierra Leone considering the utilization of three major aspects of maternal and newborn health such as eight ANC contacts, skilled birth attendance, maternal and neonatal postnatal care as well as their association with various socio-demographic and household related factors.

This study revealed that most women and their newborns did not receive maternal and newborn health services continuously. As per our results only 22% utilized 8 or more ANC contacts, 88% had skilled birth attendance while 90.7% and 90.4% of mothers and neonates utilized PNC respectively. However, only 17.9% of women in Sierra Leone utilized complete CoC for maternal and newborn at all three levels. This low completion rate of CoC in the country could imply an increased likelihood of maternal complications and neonatal mortality, as many women and their children miss proven interventions at various contact points of the continuum. The results clearly showed that the new WHO eight ANC contacts model is yet to be institutionalized among women of childbearing age in Sierra Leone. Women attended ANC after first trimester, from southern region, richer, used internet and had no big problem seeking permission were significantly associated with utilization of complete CoC for maternal and newborn health services at the three levels.

The magnitude of CoC is higher than those of studies conducted in a rural district of Lao People's Democratic Republic [24] Ghana [14] and Cambodia [25], as only 6.8%, 7.9% and 5.0% continued to receive CoC for maternal and newborn services at the three levels respectively. It is lower than those of studies conducted in Zambia [1], Egypt (50%) [19] and Pakistan (27%) [12]. These countries show that the disparities in utilization of complete continuum of care is because of shortages in human, financial and inadequate health system infrastructure, even though different ways of assessing continuum of care were used. The low level in Sierra Leone could be explained by the impact of Ebola outbreak on reproductive health services among other socio-demographic factors [26].

Timing of ANC initiation was associated with utilization of complete CoC for maternal and newborn health services. Women who had their first ANC visit after the first trimester had less odds of utilizing complete continuum of care compared to those who initiated ANC in their first trimester which similar finding was shown in Zambia [1]. A plausible explanation is that, the time at which first ANC visit is done has the utmost importance to ensure optimal health effects for both women and children [1]. This enables women to have more ANC contacts which offer an opportunity to establish baseline information on her general wellbeing, maternal and child counselling and education and creates good rapport with her health care provider hence increasing the chances of linking to the other components of continuum of care and promoting completion [27, 28]. Kinney et al. while analyzing data from sub-Saharan Africa showed that women who had initiated ANC from the first trimester had lower odds of maternal complications and mortality [29]. Therefore, there is need for stakeholders to promote timely ANC initiation as a way of ensuring increased CoC utilization.

Women from the Southern region demonstrated a more likelihood of utilizing the complete continuum of care package compared to those from the Western region. Similarly, studies conducted in Ghana, Pakistan and Zambia documented the role of regional disparities in explaining the utilization of complete CoC [1, 12, 15]. Post-conflict in Sierra Leone, the health system has been described as fragile [26]. The Western region having a high concentration of skilled birth attendants with higher social amenities due to the high economic development compared to other regions [30, 31], one would expect higher CoC utilization. However, the Western region has increasingly registered a high number of urban poor and high

standards of living which has led to inequitable access and affordability of social amenities and services including public and private health facilities, which negatively affects access to healthcare [32, 33]. In addition, the Western region being highly developed has led to health non-governmental organizations implementing maternal and child health programs to concentrate on other regions such as the Southern region could also partly explain this finding.

Women belonging to richer households were positively associated with complete continuum of maternal and newborn care, a finding consistent with several other studies including one from Cambodia [34] and another from [35]. The direct and indirect costs incurred when accessing care limit the ability of women from poor households to access maternal health services [3]. This implies that lower levels of wealth can also be a barrier to accessing maternal health services hence multi-sectoral actors and different attentions are needed to eliminate financial barriers to improve the continuity of maternity care in Sierra Leone.

Women who used internet were associated with higher odds of utilizing complete continuum of care compared to those who did not use. Similarly, a study conducted in an urban city in Nigeria suggests that internet is more popular compared to television and radio due to its high degree of interactivity, confidential and easily accessible especially on sensitive topics like reproductive health [36]. A review article revealed the important role the internet plays for women during pregnancy as it helps them to seek information in their early days of pregnancy and to make informed decisions [37]. The reasons behind the popularity of internet use in Sierra Leone could be that the internet provides various platforms to search information on maternal health as needed and equips the women with maternal health information on the importance of utilizing the continuum of care package [38].

Women who did not have a big problem in seeking permission to access a health facility were more likely to complete the three levels of continuum of care compared to those who had a big problem. High decision-making power has been shown to increase ANC contacts in Benin [39]. Increased decision-making power results from increased autonomy and empowerment among women, which depicts more access to health information and financial independence such that decisive decisions about her health are solely made by her [40].

Strengths and Limitations.

The novelty of this study stems from the fact that, it is the first of its kind to have investigated continuum of care considering the current WHO guidelines in Sierra Leone. The study made use of cross-sectional survey data, which reflect the views of women aged 15-49 across the entire country and as such, the results and conclusions are based on a nationally representative survey. However, the study had some limitations. First, the data were collected based on women's self-reports. This may lead to recall bias, information bias or social desirability bias. Second, the cross-sectional nature of the study does not permit causal inferences to be made. Lastly, the study included women who gave birth within five years preceding the survey (2015-2019) yet the WHO ANC guidelines were introduced in 2016 so considering the 8 ANC recommended contacts risks a lower prevalence of utilization of these ANC contacts.

Conclusion

The low completion rate of the entire continuum of maternal care shown in this study indicates that women in Sierra Leone are not receiving the maximum possible health benefits from the existing health services. The predictors of completion of CoC have been demonstrated to operate at various levels - individual, household and community hence highlighting a need to contextualize efforts. Efforts to promote the use of maternal health services need to focus on regional differences in utilizing CoC, women with no access to internet, those with low autonomy, and those with low socio-economic status. Further research is needed in investigating and understanding why women do not complete the continuum of maternity care. Besides, programs promoting maternal health utilization should emphasize accessing the full package rather than only specific components.

No funding was obtained for this study.

Availability of data and materials

The data set used is openly available upon permission from MEASURE DHS website (URL: <https://www.dhsprogram.com/data/available-datasets.cfm>). However, authors are not authorized to share this data set to the public but anyone interested in the data set can seek it with written permission from MEASURE DHS website (URL: <https://www.dhsprogram.com/data/available-datasets.cfm>).

Author contributions

QS Conceived the idea, drafted the manuscript, performed analysis, interpreted the results and drafted the subsequent versions of the manuscript. KK, MWM, LMM, LN and RKM reviewed the first draft and drafted the subsequent versions of the manuscript. All authors read and approved the final manuscript.

Ethics approval and consent to participate

High international ethical standards are ensured during MEASURE DHS surveys and the study protocol is performed in accordance with the relevant guidelines. The SLDHS 2019 survey protocol was reviewed and approved by the Sierra Leone Ethics and Scientific Review Committee and the ICF Institutional Review Board. Written informed consent was obtained from human participants and written informed consent was also obtained from legally authorized representatives of minor participants.

Consent for publication

Not applicable.
