Moderate innovator trap – Does convergence of innovation performance occur in the world economy?

Abstract: Based on β and σ convergence analysis, we find high persistence of innovation gap for international innovation indices reported by the European Commission. Our research confirms the diverging scientific potential across the analyzed economies. On the other hand, estimation provides the evidence of convergence in case of R&D expenses and relative position on global technological frontier. We propose a simple fixed effect panel regression measuring relative innovativeness potential. Our model suggests that current ranking leaders i.e. Nordic countries (Sweden, Denmark and Finland) and Germany are likely to further outpace the United States. Central and Eastern Europe countries are achieving greatest relative gains, but are unlikely to exceed 70% of US potential. Peripheral Europe countries, South Africa, Turkey and Russia are projected to further lose innovativeness position, despite weaker initial position.

Keywords: β convergence; σ convergence; innovation; moderate innovators; China.

1. Introduction

An increasing research interest on the structural changes taking place in the world economy has been observed in the last years. In particular the emergence of high and medium-high technology industries in emerging markets, like China attracts greatest attention. The perspective of global growth convergence has begun to rise a question as developed economies are more and more based on the use of knowledge. The middle-income trap concept has been several times invoked [1], [2]. The idea highlights that developing economies have problems to exceed certain threshold of GDP per capita. The problem is commonly linked with exhaustion of benefits from imitating the solutions of the developed markets and lack of capacity to provide innovative solution.

In order to measure the level of innovativeness of different countries, the European Commission introduced the European Innovation Scoreboard – a dataset consisting of 27 indicators describing e.g. scientific capabilities, Research & Development expenditure or intense of knowledge-rich activities. The studies analyzing trends in innovation potential of the European Union countries highlighted the divergence across regions. [3], [4]. This Paper extends the geographical scope of the research and includes other international economies scrutinized by the European Commission, aiming to answer the question if there is convergence

in the world economy with respect to innovation performance of developed and developing countries.

We propose a simple fixed effect panel regression measuring relative innovativeness potential. Our model suggests that current ranking leaders i.e. Nordic countries (Sweden, Denmark and Finland) and Germany are likely to further outpace the United States. Central and Eastern Europe countries are achieving greatest relative gains, but are unlikely to exceed 70% of the US potential. Peripheral European countries, South Africa, Turkey and Russia are projected to further lose position comparing to other developed economies.

This paper is structured as follows: the next sections presents arguments arguing for possible divergence in the innovative activities. Section 2 describes European Commission Summary Innovation Indices – probably the most comprehensive measure of various aspects of innovations. Secondly. It also presents methodology of our research and provides insight in different measurement techniques of convergence. Section 3 summarize results of the estimates. Section 4 discusses the results. Finally, section 5 concludes the paper.

2. Methods

During this section we introduce the European Innovation Scoreboard – a ranking proposed by the European Commission to measure innovative potential of the EU28 economies as well as other international peers (including e.g. United States, Switzerland, Japan or China).

The innovative potential does not have a single measure. Most popular strain in macroeconomic theory associates innovation with a presence of national companies on the global technological frontier and achievement of the higher labor and multifactor productivity [5]–[7]. Firm level studies suggest that convergence is not always a case even in the developed economies. While [5] confirmed that the process of catching up exists based on UK industrial firms' data, numerous researchers provide evidence that technology gap between leading innovators and moderately innovative areas remains persistent in several industries [7], [8]. In a cross-country perspective, less productive firms tend to converge only towards the local (national) frontier rather than global one [9].

From the perspective of less developed countries, technological catch-up typically relies on Foreign Direct Investments (further FDIs) and their positive spillovers. Theoretically, technological transfer from developed economies with the labor turnover on emerging markets should improve human capital and regional potential output. Unfortunately, the FDIs are not costless and have their limitations. The most crucial barrier visible in the laggard countries is the lack of absorptive capacity [10]. Firms from developed countries typically shift the

production to emerging states only for a product, where technical requirements are only slightly above current technological frontier of hosting economy [11]. There is often also a conflict of interest between needs of multinational companies providing capital and the native society needs. Authors highlight that an in-house Research and development (R&D) expenditures and motivations systems for domestic investments are required to benefit from foreign capital expenses [12], [13].

Another problem is related to regional system and network connections [14]. Knowledge intense industries are likely to cluster within narrow geographical areas. Numerous authors confirmed that intellectual property (PCT patents) is typically used by firms remaining in the geographical proximity to the inventor [15], [16]. Finally, more interconnected countries have greater capability to introduce and exports new products [17].

The European Innovation Scoreboard directly address all of the mentioned problems. Therefore, we do believe the study should be most comprehensive and adequate to perform convergence analysis. The general summary innovation index for a European Union country is a synthetic indicator computed as an average of 27 subcomponents divided in the four pillars. Due to the data limitations indices for international economies contains only 16 subcomponents. The indices are reported annually typically in the middle of the year (June-July).

First pillar titled Framework Conditions contains 8 indicators for the European Union countries and only 4 for international economies. The variables available in both groups describes scientific potential of the society e.g. number of doctorate graduates, share of people with the tertiary education, as well as research capacity – i.e. international scientific publications, share of country publications amongst top 10% most cited papers. European indicators additionally account for innovation-friendly environment, including broadband penetration and opportunity driven entrepreneurship, cultural diversity (foreign doctorate students) and lifelong learning.

Second pillar – Investments contains two variables internationally: Research and Development (R&D) expenditure int the business sector and in the public sector. European countries report also another three variables: non-R&D innovative outlays, expansion of venture capital and availability of ICT training.

The third pillar – Innovation activities (9 variables within EU, 8 internationally) is focused on three aspects. First aspect describes engagement of the Small and Medium Enterprises (SME) in the innovative activities. This group consist of two variables – first one describes product or process innovation second marketing or operational improvement. The data tables will use shortcut acronyms: respectively PP innovators and MO innovators, used by the

European Commission. European countries report also whether innovative activities were done in-house or outsourced.

Secondly the survey promotes cooperation between entities and creating regional networks. The three variables belonging to this aspect describes collaboration of SME enterprises, number of private-public partnerships co-publications per thousand inhabitants, and share of collaborative R&D expenses as a percent of the Gross domestic product (GDP).

The final aspect is dedicated to accumulating and using of intellectual property rights. European Commission tracks the number of patent application under PCT procedure (acronym stands for Patent Cooperation Treaty), trademarks and individuals design. Number of applications is divided per GDP in Purchasing Power Standard.

Finally, the fourth pillar Impact relies strongly on the concept of technological frontier. This group contains 2 common indicators for international and European Union economies: share of knowledge intense services in total services export (further KIS exports) and share of medium & high-tech products in total goods exports (further MHT exports). European indicators have additional 3 measures: first employment in knowledge intense activities, second employment fast growing innovative firms and finally the third frequency of introduction of the innovative products. (Sales of new-to-market and new-to-firm innovations).

The European Commission transforms each of mentioned variable and express it with a normalized score index, which takes values from 0 to 1 (see methodology annex for further details). Higher number denotes stronger innovative potential.

The summary innovation index is calculated as an average of normalized scores from 28 indicators for European Union countries and 16 indicators for international economies. We have modified indices for the EU countries to match the indicators from international database, averaging 16 common subcomponents only. Such transformed indicators were used during all of the estimations.

The overall panel consist of EU27 countries, other European economies reporting all 28 indicators (United Kingdom, Iceland, Israel, Norway, Switzerland, Turkey) and the group of international economies (Canada, Australia, Japan, United States, China, Brazil, South Africa, Russia, India). The research covers the period from 2010 to 2017 – indicators are collected once per annum.

Our aim is to determine whether cross-country convergence of innovation occurs. We introduce two measures of concurrences: β and σ [18], [19]. Secondly, we introduce simple relative models distinguishing between in-house innovative capacity and imitations [12].

The most popular concept of convergence (β) assumes that less developed countries/areas are growing more swiftly comparing to the more affluent peers. Let's denote $innov_t$ as summary innovation index at the time t . We expect to see a positive relationship of average annual change during the period 2010-2017 and starting level $innov_0$ (index value at 2010).

$$\frac{(innov_t - innov_0)}{T} = \delta_0 + \delta_1 * innov_0 \quad (1)$$

Where δ_1 should take a negative value if convergence exist. On the other hand, a positive value of this parameter denotes divergence. We are going to repeat calculations for every single component creating summary innovation index.

Secondly, we also attempt to use another measure – σ -convergence. The idea of such indicator assumes that if convergence exists cross-country standard deviation should diminish over elapsed time. The downward trend should be visible, when using following formula.

$$std(innov_t) = \alpha_0 + a_1 * T \quad (2)$$

We expect a_1 parameter in equation (2) to have negative value, otherwise divergence occurs. Similarly like in case of β -convergence the estimation will be repeated for all innovation index components.

Finally, subject literature tends to distinguish between capability of in-house innovation and imitations, we proposed a simple fixed-effects panel model:

$$d\left(\frac{innov_t}{innov_{USA_t}}\right) = \beta_0 + \mu + \beta_1 * \left(\frac{innov_{t-1}}{innov_{USA_{t-1}}} - 1\right) \quad (3)$$

Where μ is a cross-country estimated fixed effect, $innov_{t-1}/innov_{USA_{t-1}} - 1$ is a relative distance of the country summary innovation index to United States (selected as a benchmark), β_0 and β_1 are estimated parameters.

This model has relatively straightforward economic interpretation. Parameters $\beta_0 + \mu$ describes in-house innovative potential. The negative sum indicates that country is expected to remain in the middle innovation trap, as it is unlikely to catch up the United States. β_1 can be identified with improvement of innovative potential done by imitations. We expect the parameter to be negative. In such case countries lying far below technological frontier are more likely to catch-up stronger. (in line with β convergence spirit). Based on that model we are capable to calculate the steady-state where:

$$0 = \beta_0 + \mu + \beta_1 * \left(\frac{innov^*}{innov_{USA}^*} - 1\right) \quad (4)$$

The result of such exercise should present expected relative performance in case of no policy change scenario.

3. Results

This section discusses our findings on innovative capacity convergence. We proposed three measures determining if countries described as moderate innovators are catching up towards the innovation leaders.

The results of β convergence analysis is presented in the Table 1. Third column contains estimates of parameter δ_1 - the negative values indicates that less developed countries are catching up the distance to current leaders. The last column presents whether estimates are statistically significant.

Table 1 – β convergence.

*** denotes significance at $\alpha = 0.01$, ** at $\alpha = 0.05$, * at $\alpha = 0.10$

The estimate corresponding to the Summary Innovation Index does not differ from zero, suggesting quite persistent status quo between innovative potential across the countries. The analysis of subcomponents presents three major significant trends: 1) convergence of R&D expenditures in both business and public sector and related to them position of countries' production on the global technological frontier. 2) possible divergence of scientific potential with greater internationalization of research in developed countries. 3) The relatively stable position in case of using intellectual property rights (PCT patents, designs and trademarks) and SME activities, especially when it comes to product or process innovation.

The results of σ convergence analysis are available in the table 2. The data columns 2-9 contain cross country standard deviation observed in the subsequent years. Columns 10-11 present the estimated parameters. Column 12 answers if parameter α_1 is statistically significant.

Table 2 – σ convergence.

Doctorate graduates	0.27	0.28	0.27	0.27	0.29	0.30	0.30	0.30	0.26	4.94	***

Parameters a_1 were scaled (multiplied by 1000) to visualize whether trend has upward or downward slope. *** denotes significance at $\alpha = 0.01$, ** at $\alpha = 0.05$, * at $\alpha = 0.10$

Similarly like in case of β convergence analysis, there is no statistically significant trend for Summary Innovation Index. The indicator describing slope of time trend in a cross-country standard deviation takes value, which statistically not differs from 0.

The σ convergence analysis confirms also the divergence of scientific potential – cross country standard deviation is in an upward trend in case of indicator describing the number of doctorate graduates in population and the internationalization of scientific publications. The divergence is also statistically significant in case of selected SME activities – product and process innovations and international co-operation.

Similarly, to the first analysis there are a statistically significant evidence of convergence in marketing and operational innovations and knowledge intense services export.

Finally, we estimated simple model of Summary Innovation Index dynamics. Small countries i.e. those whose population does not exceed 4 million people were excluded from the sample in order to eliminate potential outliers. The data for Luxembourg, Malta, Cyprus, Croatia Slovenia, Iceland, Baltic states (Estonia, Latvia and Lithuania) were not used during the estimations.

Model parameters are presented in table 3.

Poland	-0.16	-0.23	43%	44%	0.6%
Portugal	-0.06	-0.13	69%	68%	-0.3%
Romania	-0.21	-0.28	29%	32%	3.1%
Russia	-0.15	-0.22	49%	47%	-1.9%
Slovakia	-0.12	-0.19	53%	55%	1.7%
South Africa	-0.14	-0.21	49%	48%	-1.5%
Spain	-0.07	-0.14	66%	65%	-0.8%
Sweden	0.19	0.12	127%	128%	1.7%
Switzerland	0.23	0.16	140%	139%	-1.3%
Turkey	-0.17	-0.24	43%	41%	-2.2%
UK	0.09	0.02	106%	104%	-1.4%

Our model suggests that current ranking leaders i.e. Nordic countries (Sweden, Denmark and Finland) and Germany are likely to further outpace the United States position in the innovativeness ranking. Central and Eastern Europe countries including Poland, Hungary, Czech Republic or Romania are achieving greatest gains, but are unlikely to exceed 70% of US potential.

Another interesting example is China – our model indicates nearly stable potential (at 76% of the United States level), after rapid expansion in the years 2010-2014. The European Commission report constant depression in the export of knowledge intense serviced export. The

construction of ranking is likely to underestimate the innovative potential e.g. on artificial intelligence related to strategy Made in China 2025 (as technology is utilized in the domestic market only).

On the other hand, peripheral Europe countries (Greece, Spain Portugal and Ireland) are projected to lose innovativeness position. The same problem is related to South Africa, Turkey and Russia despite their low initial position.

4. Discussion

Contrary to the research outcomes for the European Union countries [3], [4], we found no statistically significant divergence trend for international Innovation Indices reported based on both β and σ convergence analysis and our fixed effects model. Still our research confirmed that technological gaps are highlight persistent and there are neither no signs of convergence.

Based on the subcomponents analysis we found divergence of scientific potential measured by number of doctorate students in population (σ convergence) and international co-publications (both measures). Our research indicates also problem with diverging process and product innovations amongst SME enterprises. On the other hand, there are signs of convergence in case of position on technological frontier and R&D expenses. Both β and σ analysis confirmed spreading of marketing and operational innovations and knowledge intense services exports.

Geographical model suggests consolidation of division between core and peripheral European Union countries [20], as well as North-South division in the global context [21]. The Nordic countries and Germany are expected to increase innovative potential, while peripheral economies are projected to lose position in comparison with the United States. Similarly, Central and Eastern Europe are expected to develop in a fastest manner, but still its potential should remain strongly below the level of Wester economies. Finally, less developed countries like South Africa, Russia, Turkey or India show limited potential for increase of technological potential.

5. Conclusions

The research identified lack of convergence of innovative potential between countries. According to the model the strong discrepancy between highly innovative North and less developed South of the European Union members is unlikely to vanish in the foreseeable future. The problem is even stronger in comparison between developed and emerging economies. The

uneven innovative potential is likely to limit growth opportunities in the emerging markets and solidify well-known middle-income traps.

Secondly, we identified strong divergence of scientific and research potential. This phenomenon may result in a problem of the brain drain i.e. migration of skilled individuals from the peripheral countries to the leading innovation centers in order to pursue career opportunities. The uneven distribution of skilled cognitive jobs is also likely to result in social tension between the regions – some prelude of this problem was already visible in the USA, where abandoned rust belt played decisive role in the election or France, where yellow jackets movement violently protested against inequality.

In order to prevent such events governments and international organizations such as the European Union should probably reconsider implementing deglomeration policies, aimed to provide incentives for multinational companies to diversify geographically knowledge intense activities. So far, such instruments were applied only regionally – for example in post-war Germany.

Declarations

Availability of data and materials

Data supporting the results reported in the article can be at the European Innovation Scoreboard – a ranking proposed by the European Commission to measure innovative potential of the EU28 economies as well as other international peers (including e.g. United States, Switzerland, Japan or China).

Competing interests

The authors declare no conflict of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

Funding

The paper was prepared in the framework of the research project No 2016/21/B/HS4/03025 “Dynamics and factors of innovation gap between Poland and China – international and regional dimensions”, financed by the National Science Center, Poland.
