Abstract

Background

Chronic cerebral hypoperfusion (CCH) is regarded as a high-risk factor for cognitive decline in vascular dementia (VaD). We have previously shown that diabetes mellitus (DM) synergistically promotes CCH-induced cognitive dysfunction via exacerbating neuroinflammation. Furthermore, curcumin has been shown to exhibit anti-inflammatory and neuroprotective activities. However, the effects of curcumin on CCH-induced cognitive impairments in DM have remained unknown.

Methods

Rats were fed with a high-fat diet (HFD) and injected with low-dose streptozotocin (STZ), followed by bilateral common carotid artery occlusion (BCCAO), to model DM and CCH *in vivo*. After BCCAO, curcumin (50 mg/kg) was administered intraperitoneally every two days for eight weeks to evaluate its therapeutic effects. Additionally, mouse BV2 microglial cells were exposed to hypoxia and high glucose to model CCH and DM pathologies *in vitro*.

Results

Curcumin treatment significantly improved DM/CCH-induced cognitive deficits and attenuated neuronal cell death. Molecular analysis revealed that curcumin exerted protective effects via suppressing neuroinflammation induced by microglial activation, regulating the triggering receptor expressed on myeloid cells 2 (TREM2)/toll-like receptor 4 (TLR4)/nuclear factor- κ B (NF- κ B) pathway, alleviating apoptosis, and reducing nod-like receptor protein 3 (NLRP3)-dependent pyroptosis.

Conclusions

Taken together, our findings suggest that curcumin represents a promising therapy for DM/CCH-induced cognitive impairments.

Introduction

As the second-leading cause of dementia following Alzheimer's disease (AD), vascular dementia (VaD) is characterized by memory decline and cognitive dysfunction^[1]. Chronic cerebral hypoperfusion (CCH), a chronic state of reduced cerebral blood flow, has been associated with the pathological processes of VaD resulting from disorders affecting the cerebral vascular system, including hypertension, diabetes, generalized atherosclerosis, and smoking^[2–5]. As a chronic metabolic disease, the prevalence of diabetes mellitus (DM) has increased worldwide^[6]. Notably, epidemiological studies have established an increased risk of dementia among individuals with DM^[7, 8]. Accumulating evidence has also revealed that DM interacts with CCH to promote the pathophysiological progression of neurodegenerative

disorders^[9, 10]. Furthermore, our previous studies have demonstrated that DM synergistically promotes CCH-induced cognitive dysfunction^[11].

At present, the potential mechanisms of CCH-induced VaD are related to hippocampal neuronal injury, white matter damage, neuroinflammation, and oxidative stress. Among these factors, neuroinflammation has recently received increased attention^[12–15]. Neuroinflammation mainly occurs through the activation of microglia and subsequent production of neurotoxic pro-inflammatory cytokines, which further induce neuronal damage and even neuronal death, resulting in brain damage^[16, 17]. A recent study found that in a rat model of CCH, synaptic plasticity was significantly impaired along with an increase in microglial activation, thus contributing to cognitive deficits^[18]. A number of signaling molecules, including toll-like receptor 4 (TLR4)/nuclear factor- κ B (NF- κ B) and triggering receptor expressed on myeloid cells 2 (TREM2), are essential for modulation of microglial activation and neuroinflammation. TREM2 is an important innate immune receptor that is expressed uniquely on microglia in the central nervous system and participates in down-regulating neuroinflammation^[19]. Consistently, our previous study also demonstrated that there was an imbalance between microglial TLR4- and TREM2-mediated microglial polarization and neuroinflammation in lipopolysaccharide (LPS)-treated BV2 cells^[20]. However, the role of the TREM2/TLR4 pathway in DM/CCH-induced pathologies has remained unclear.

As previously reported, apoptosis is thought to be involved in the occurrence and development of VaD^[21–23]. Some studies have shown that increased activation of mitochondrial apoptotic markers (e.g., caspase 3) leads to destruction of the blood-brain barrier, inflammation, and oxidative stress, and eventually results in brain damage^[22, 24, 25]. Moreover, pyroptosis, a pro-inflammatory form of programmed cell death, also contributes to the pathogenesis of neurodegenerative diseases such as AD and Parkinson's disease (PD)^[26, 27]. Nod-like receptor protein 3 (NLRP3) inflammasome is known to contribute to upstream signaling of pyroptosis^[28–30]. After activation, NLRP3 inflammasome triggers cleavage and activation of caspase 1, which mediates pyroptosis^[28]. However, whether apoptosis and pyroptosis promote the progression of VaD in DM patients remains unclear.

Curcumin, derived from the rhizome of *Curcuma longa* Linn, is a bright yellow spice that shows strong anti-inflammatory, anti-oxidant, and anti-tumor activities^[31, 32]. Many studies have reported neuroprotective effects of curcumin in neurodegenerative diseases, including AD, PD, and multiple sclerosis^[33–36]. Our previous study has also demonstrated a protective effect of curcumin on LPS-induced neuroinflammation *in vitro*^[20]. However, whether curcumin exerts neuroprotective effects on DM/CCH-induced pathologies has remained unknown.

In the present study, to investigate the protective effects and mechanisms of curcumin, we established an *in-vivo* rat model of DM/CCH induced by a high-fat diet (HFD) and streptozotocin (STZ) treatment, followed by bilateral common carotid artery occlusion (BCCAO). Additionally, we established an *in-vitro* model of DM/CCH-induced pathologies in mouse BV2 microglia exposed to hypoxia and high glucose .

Methods

3.1. Animals

Healthy adult male Sprague-Dawley (SD) rats (six weeks old, 160–180 g) were used in the present study. Rats were housed under a controlled temperature (23 ± 1 °C) and a 12-h light/dark cycle, and were provided food and water *ad libitum*. All experiments were approved by the Institutional Animal Care and Use Committee of Shanghai Jiao Tong University.

3.2. Rat model of DM and CCH

After one week of acclimatization, the rats were randomly divided into four groups: sham surgery (Sham group), sham + curcumin (Cur group), DM + two-step BCCAO (DM/CCH group), and DM + BCCAO + curcumin (DM/CCH + Cur group) (n = 9 per group). Our DM rat model was established according to the methods reported in our previous studies^[11, 37]. Briefly, the diabetic rats were fed with a HFD (60% fat, 20% carbohydrate, and 20% protein) while non-diabetic rats were fed with a low-fat diet (LFD) (10% fat, 70% carbohydrate and 20% protein). After six weeks on these feeding regimens, rats fed with a HFD were intraperitoneally administered with a single dose of STZ (30 mg/kg). One week after the STZ injection, 1.0 mL of blood was collected from the tail vein of each injected rat. Rats were considered diabetic when their blood glucose reached 16.7 mM one week after injection of STZ. Two weeks after injection of STZ, rats received sham surgery or two-step BCCAO according to a previously described procedure^[38]. Briefly, rats were anesthetized by an intraperitoneal injection of chloral hydrate (350 mg/kg) and were then fixed in a supine position. A midline cervical incision was made, and both the left and the right common carotid arteries were carefully isolated from the vagus nerve. In the DM/CCH and DM/CCH + Cur groups, the bilateral common carotid arteries were permanently ligated with #4 surgical thread, and the left common carotid artery was occluded first; then, one week later, the right common carotid artery was occluded. The Sham and the Cur groups underwent the same surgical procedure without BCCAO. During the surgery, body temperature was maintained at approximately 37 °C by a heating pad. Of the 18 rats in the BCCAO groups, two rats (11%) died on the first day after operation, which may have been due to excessive anesthesia and/or surgical injury.

3.3. Curcumin preparation and treatment

Curcumin (0.1 g) was dissolved in 1 mL of dimethylsulfoxide (DMSO) and diluted with 9 mL of oil. In the Cur and DM/CCH + Cur groups, each rat was intraperitoneally injected with 1.5 mL of curcumin (50 mg/kg) every two days for eight weeks after BCCAO.

3.4. Morris water maze (MWM)

Spatial learning and memory abilities of all rats were evaluated via the Morris water maze (MWM) at eight weeks after BCCAO was performed. The MWM was carried out in a large circular black pool with a diameter of 180 cm and a height of 50 cm, which was filled with water (24 ± 1 °C). Charcoal-black ink was added to make the water opaque. The pool was divided into four equal quadrants, and a movable

hidden platform (10 cm in diameter) was placed 2 cm below the surface in the second quadrant of the MWM. The MWM included two steps. The first step was the place navigation test, which was conducted four times a day for five consecutive days. Each rat was gently placed in the water from a different quadrant facing the inner wall of the pool. Once within the MWM, rats were allowed to swim for up to 60 s. Once each rat reached the platform, it was allowed to remain on the platform for 20 s. If the rat failed to find the hidden platform within 60 s, it was gently placed on the platform for 20 s. In each test, the time that the rat took to reach the hidden platform was recorded as the escape latency. The second step of the MWM was the spatial probe test, which was performed on the sixth day and included removal of the hidden platform. During the spatial probe test, each rat was placed in the opposite quadrant to that of the target quadrant and allowed to swim freely for 60 s. The time spent in the target quadrant, the number of times crossing the area in which the platform was located previously, and the average swimming speed were measured.

3.5. Tissue preparation

All rats were sacrificed after completing the MWM. Brains were perfused with 0.9% cold saline and were immediately separated into two hemispheres. One of the hemispheres was rapidly frozen in liquid nitrogen for tissue biochemical analysis, while the other hemisphere was fixed in paraformaldehyde (4%) at 4 °C for 24 h for histological or immunohistochemical detection.

3.6. Immunostaining

In order to carry out histological analysis, brain tissue sections were dewaxed, rehydrated, and stained with hematoxylin and eosin (HE, purchased from Servicebio) according to the manufacturer's instructions. Light microscopy was used to observe the histomorphology of neurons. For immunofluorescent staining, brain slices were incubated with blocking buffer (3% donkey serum, 1% BSA, and 0.3% Triton X-100 in phosphate-buffered saline [PBS]) at room temperature for 1 h after returning to room temperature. Then, the sections were incubated with the following primary antibodies overnight at 4 °C: goat anti-Iba1 (1:500, Abcam) and rabbit anti-NeuN (1:500, Abcam). After being washed three times in PBS, the sections were incubated with secondary antibodies at room temperature for 1 h in the dark. For labeling cell nuclei, sections were incubated in DAPI and an anti-fluorescent quenching agent after being washed three times in PBS. The sections were then visualized under an Olympus microscope (IX53).

3.7. Detection of apoptosis

To examine neuronal apoptosis in the hippocampus, terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) was performed. The TUNEL staining kit was purchased from Beyotime (Shanghai, China). The sections were fixed in paraformaldehyde and were then subjected to various reagents of the TUNEL staining kit, according to the manufacturer's instructions. Images were visualized under an Olympus microscope (IX53).

3.8. Cell culture and treatments

Mouse BV2 microglial cells (purchased from Shanghai Zhong Qiao Xin Zhou Biotechnology Co. Ltd) were cultured in eagle's minimum essential medium (EMEM) containing 10% fetal bovine serum and 1% penicillin/streptomycin at 37 °C with 5% CO₂. When treated with high glucose, D-glucose was added to the conventional medium to yield a final concentration of 30 mM *in vitro*. During hypoxia treatment, the cells were placed in an O₂/N₂/CO₂ incubator and exposed to 3% O₂ for 24 h. The experiments *in vitro* consisted of the following four groups: (1) cells that were cultured without any treatment (control group); (2) cells that were pretreated with curcumin (10 μM) for 2 h under normal culture conditions (Cur group); (3) cells that were exposed to high glucose (30 mM) for 24 h followed by hypoxia (3% O₂) for 24 h (HG/HP group); and (4) cells that were pretreated with curcumin (10 μM) for 2 h under high glucose combined with hypoxic conditions as described above (HG/HP + Cur group).

3.9. Cell viability assays

Cell viabilities were determined by cell counting kit 8 (CCK8) assays. Briefly, BV2 cells were seeded in 96-well plates at a density of 4,000 cells per well and were exposed to different conditions overnight according to their designated groups. After incubation with CCK8 reagent (10 μL) for 2 h, the optical density (OD) within each well was read on a microplate reader at a wavelength of 450 nm.

3.10. Flow cytometry

Cells were cultured in six-well plates and exposed to different conditions according to their designated groups. The cells were digested with trypsin and were then centrifuged. After being washed three times with cold PBS, the cells were resuspended with 100 μL of binding buffer. Then, 5 μL of annexin V-FITC and 5 μL of PI were added to react for 15 min at room temperature in the dark. Then, 400 μL of binding buffer was added to the cells and mixed softly, and then the cells were subjected to flow cytometry (CytoFLEX LX, USA).

3.11. Quantitative real-time PCR (qRT-PCR)

Total RNA was isolated from the brain tissues and cells using an RNAeasy animal RNA isolation kit (Beyotime, Shanghai, China) according to the manufacturer's instructions. Isolated RNA was reverse-transcribed to synthesize cDNA using a cDNA Synthesis kit (Takara, Japan). Then, quantitative real-time PCR (qRT-PCR) was performed using TB Green Premix Ex Taq II (Tli RNaseH Plus) with an Applied Biosystems QuantStudio 7 Real-Time PCR System. All primer sequences that we used are listed in Table 1.

3.12. Western blot analysis

Total proteins were extracted from brain tissues or cells using lysates containing RIPA buffer supplement with protease and phosphatase inhibitors. The protein concentration of each sample was determined using bicinchoninic acid (BCA) assays. Then, the proteins were separated by sodium-dodecyl-sulfate

polyacrylamide gel electrophoresis (SDS-PAGE) and were then electro-transferred onto a polyvinylidene fluoride (PVDF) membrane. After blocking with 5% milk or BSA, the membrane was incubated at 4 °C overnight with the following primary antibodies: TREM2, 1:500; TLR4, 1:200; NF-κB, 1:1000; p-NF-κB, 1:1000; Bax, 1:1000; Bcl2, 1:1000; cleaved-caspase3, 1:1000; NLRP3, 1:1000; ASC, 1:1000; caspase1, 1:1000; GSDMD-N, 1:1000; IL-18, 1:1000; and actin, 1:1000. After three washes (for 10 min each) with TBST buffer, the membrane was incubated with secondary anti-rabbit or anti-mouse antibodies for 1 h at room temperature. The protein bands were visualized using enhanced chemiluminescence.

3.13. Statistical analysis

Data are expressed as the mean ± standard error of the mean (SEM). Comparisons among different groups were performed using one-way analysis of variance (ANOVA) with SPSS 22.0. Repeated-measures multivariate analysis of variance was used to evaluate the results of the MWM. A $P < 0.05$ was considered statistically significant.

Results

4.1 Curcumin alleviates DM/CCH-induced impairments in spatial learning and memory in rats

Eight weeks after BCCAO, the MWM was used to investigate whether curcumin could alleviate DM/CCH-induced impairments in spatial learning and memory. In the hidden platform test, the DM/CCH group exhibited a significantly-prolonged escape latency compared to that of the Sham group since the second day on the MWM, especially on days 4–5 (Fig. 1B). However, curcumin treatment significantly mitigated the poor spatial learning performance resulting from DM/CCH, whereas curcumin did not induce any changes in the learning/memory performances of the Sham and Cur groups. In the probe test, the rats in the DM/CCH group exhibited fewer crossings over the location of the original platform, less time spent in the target quadrant, and more chaotic trajectories than those of the Sham and Cur groups. However, curcumin treatment dramatically mitigated these spatial memory impairments caused by DM/CCH (Fig. 1C, D, and F). There were no differences in the swimming speeds among any of the groups (Fig. 1E). Taken together, these results indicate that curcumin significantly alleviated DM/CCH-induced impairments in spatial learning and memory.

4.2 Curcumin attenuates neuronal death in DM/CCH rats

DM/CCH-induced neuronal death in the hippocampus was examined by HE and NeuN staining. HE staining revealed normal morphologies and clear boundaries of hippocampal neurons in the Sham and the Cur groups, while the DM/CCH group exhibited abnormal morphologies of shrunken neurons with dark-stained nuclei, and even missing/lost neurons. Surprisingly, curcumin treatment partially attenuated such neuronal damage (Fig. 2A). Moreover, curcumin treatment effectively restored the DM/CCH-induced decreased number of neurons in the CA1, CA3, and dentate gyrus (DG) regions of the

hippocampus (Fig. 2B). These findings suggest that curcumin attenuated DM/CCH-induced neuronal death in the CA1, CA3, and DG regions of the hippocampus.

4.3 Curcumin inhibits DM/CCH-induced neuroinflammation in the rat hippocampus

Previous studies have reported that neuroinflammation plays a vital role in the pathology of VaD^[14, 39–41]. Microglia are resident immune cells within the central nervous system and play an important role in the initiation and transmission of inflammatory responses. Thus, we investigated whether curcumin could suppress DM/CCH-induced microglial activation and production of pro-inflammatory cytokines. Iba1 was used to label microglia. As shown in Fig. 3A, activated microglia were rarely detected in the CA1 region of the hippocampus in the Sham and Cur groups, while the numbers of Iba1-positive cells were increased dramatically following DM/CCH in the hippocampus. However, curcumin inhibited this DM/CCH-induced overactivation of microglia, as microglial density was reduced compared to that in the DM/CCH group. We further detected the expression of pro-inflammatory (IL-1 β , IL-6, TNF- α , iNOS, COX2) and anti-inflammatory (Arg-1, IL-4, IL-10) cytokines in each group via qRT-PCR. As shown in Fig. 3B, IL-1 β , IL-6, and TNF- α levels were increased whereas Arg-1, IL-4, and IL-10 levels were decreased in the DM/CCH group compared with those in the Sham group. However, curcumin treatment significantly reduced this DM/CCH-induced inflammatory response, as the levels of pro-inflammatory cytokines were decreased while those of anti-inflammatory cytokines were increased compared to those in the DM/CCH group. Similarly, our *in-vitro* model confirmed that compared with those in the Control group, hypoxia combined with high glucose markedly increased IL-1 β , IL-6, TNF- α , iNOS, and COX2 levels while reducing Arg-1 levels. However, curcumin effectively reversed high-glucose/hypoxia-induced changes in expression levels of pro-inflammatory and anti-inflammatory cytokines (Fig. 3C). Meanwhile, there were no differences in levels of inflammatory cytokines between the Sham and Cur groups, either *in vivo* or *in vitro*. These results demonstrate that curcumin inhibited DM/CCH-induced and high-glucose/hypoxia-induced microglial activation and pro-inflammatory cytokine production.

4.4 Curcumin regulates TREM2/TLR4/NF- κ B signaling in DM/CCH rats and high-glucose/hypoxia-treated microglia

TLR4 and TREM2 are microglial membrane-bound receptors that play important roles in inflammatory signaling pathways^[42, 43]. Additionally, NF- κ B activation induces the release of pro-inflammatory cytokines^[44]. Therefore, in our present study, we first measured protein levels of TREM2, TLR4, and NF- κ B via Western blotting *in vivo*. As shown in Fig. 4A and B, the protein levels of TREM2, TLR4, and phosphorylated NF- κ B p65 (p-NF- κ B p65) were increased in the DM/CCH group compared with those in the Sham group. Interestingly, curcumin treatment effectively inhibited TLR4 and p-NF- κ B p65 levels, whereas it further increased TREM2 levels. No significant differences were found in terms of NF- κ B p65 levels. Furthermore, our results *in vitro* were similar to those *in vivo*. As shown in Fig. 4C and D, the expression levels of TREM2, TLR4, and p-NF- κ B p65 were significantly increased in the high-glucose/hypoxia-treated group compared with those in the Control group. After curcumin treatment,

TLR4 and p-NF- κ B p65 levels were dramatically decreased while TREM2 levels were further increased. Meanwhile, we also measured mRNA levels of TREM2 and TLR4 both *in vivo* and *in vitro*. As shown in Fig. 4E and F, our results of mRNA levels were consistent with those of protein levels. There were no differences in the measured mRNA or protein levels between the Sham (Control) and Cur groups. Therefore, these results suggest that curcumin inhibited neuroinflammation by regulating the TREM2/TLR4/NF- κ B pathway in both DM/CCH rats *in vivo* and high-glucose/hypoxia-treated microglia *in vitro*.

4.5 Curcumin suppresses apoptosis in DM/CCH rats and high-glucose/hypoxia-treated microglia

As previously reported, apoptosis is involved in the development of VaD^[45, 46]. Hence, we first investigated the levels of apoptosis-related proteins (Bax, Bcl2, and cleaved-caspase3) via Western blotting *in vivo*. As shown in Fig. 5A and B, DM/CCH rats exhibited higher levels of Bax and cleaved-caspase3 and lower levels of Bcl2 compared to those in the Sham group, whereas these changes in protein levels were reversed by curcumin. Furthermore, our results *in vitro* were consistent with those *in vivo*. As shown in Fig. 5C and D, curcumin effectively reversed high-glucose/hypoxia-induced overexpression of Bax and cleaved-caspase3 and restored Bcl2 levels in microglia *in vitro*. Furthermore, qRT-PCR confirmed that curcumin reduced the mRNA levels of Bax and cleaved-caspase3 while increasing Bcl2 mRNA levels both *in vivo* and *in vitro* (Fig. 5E and F). In contrast, there were no significant differences in any measured mRNA or protein levels between the Sham (Control) and Cur groups.

Next, we used TUNEL staining to examine neuronal apoptosis *in vivo*, and Annexin-FITC/PI double staining as well as CCK8 assays to examine microglial death *in vitro*. As shown in Fig. 6A, DM/CCH rats exhibited a higher number of TUNEL-positive cells in the CA1 region of the hippocampus compared with that in the Sham group. Strikingly, curcumin treatment significantly reduced the number of TUNEL-positive cells. Annexin-FITC/PI double staining revealed that curcumin effectively suppressed high-glucose/hypoxia-induced microglial apoptosis (Fig. 6B and C). Our results also demonstrated that cellular survival rates were decreased dramatically in response to hypoxia and high glucose, while curcumin treatment effectively restored cellular viability (Fig. 6D). There were no significant differences in terms of apoptosis between the Sham (Control) and Cur groups. Taken together, these findings suggest that curcumin suppressed apoptosis following DM/CCH *in vivo* or high-glucose/hypoxia *in vitro*.

4.6 Curcumin mitigates NLRP3-dependent pyroptosis in DM/CCH rats and high-glucose/hypoxia-treated microglia

Accumulating evidence has demonstrated that NLRP3-dependent pyroptosis is involved in the progression of neurodegenerative diseases^[47, 48]. Therefore, Western blotting and qRT-PCR were used to detect protein and mRNA levels, respectively, of NLRP3, apoptosis-associated speck-like protein containing a CARD (ASC, which is an adaptor protein connecting pattern-recognition receptors and pro-caspase1), cleaved-caspase1, cleavage of gasdermin D (GSDMD-N, a protein substrate of caspase1 that

has been identified as an executive molecule in pyroptosis), and IL-18 *in vivo* and *in vitro*. As shown in Fig. 7A and B, curcumin treatment significantly reduced DM/CCH-induced overexpression of NLRP3, ASC, cleaved-caspase1, GSDMD-N, and IL-18 proteins. Our results *in vitro* were similar to those *in vivo*, as shown in Fig. 7C and D. The protein levels of microglial NLRP3, ASC, cleaved-caspase1, GSDMD-N, and IL-18 were increased after exposure to high glucose and hypoxia, whereas these changes in protein levels reversed by curcumin treatment. Similarly, curcumin effectively attenuated DM/CCH-induced or high-glucose/hypoxia-induced increases in mRNA levels of NLRP3 and IL-18. These findings indicate that curcumin mitigated NLRP3-dependent pyroptosis in DM/CCH rats and high-glucose/hypoxia-treated microglia.

Discussion

To investigate the protective effects of curcumin on DM/CCH-induced pathologies, our previous studies have successfully established stable models *in vivo* and *in vitro*^[11, 38]. Specifically, we subjected rats to a HFD and low-dose STZ combined with BCCAO to model DM/CCH *in vivo*, whereas we established a corresponding model *in vitro* by subjecting BV2 microglia to hypoxia and a high-glucose environment. The present study revealed that curcumin treatment effectively protected against DM/CCH-induced cognitive dysfunction, as well as attenuated neuronal injury and death in the CA1, CA3, and DG regions of the hippocampus. Molecular-biology analysis revealed that the underlying mechanisms of curcumin's protective effects were associated with inhibiting neuroinflammation, regulating the TREM2/TLR4/NF- κ B pathway, suppressing neuronal apoptosis, and mitigating NLRP3-dependent pyroptosis.

CCH plays a pivotal role in the progression of cognitive impairments in VaD, as it can induce neuroinflammation, decrease energy supplementation, contribute to neuronal injury, and impair memory^[18, 49, 50]. Importantly, a previous study has demonstrated that diabetes aggravates neuronal apoptosis and accelerates cognitive dysfunction^[51]. In our present study, in the MWM, the DM/CCH group exhibited impairments in spatial learning and memory, as revealed by a prolonged escape latency, decreased number of crossings over the original platform location, and less time spent in the target quadrant; these findings are consistent with those of previous reports^[11, 52, 53]. However, long-term curcumin treatment significantly ameliorated cognitive dysfunction. Moreover, we found that curcumin attenuated DM/CCH-induced neuronal damage, as there was an increase in NeuN-positive cells and HE staining showed a decrease in atrophied neurons and dark-stained nuclei; these results were consistent with our behavioral results in the MWM. Collectively, these findings indicate that curcumin protected against cognitive impairments and attenuated neuronal damage in DM/CCH rats.

Accumulating evidence has demonstrated that CCH induces significant inflammatory responses, including glial activation and excessive production of pro-inflammatory cytokines (e.g., IL-1 β , IL-6, TNF- α), which are pathological signatures that are closely related to neuronal damage^[54]. Moreover, previous studies have also found that DM increases microglial activation and the release of pro-inflammatory cytokines^[55, 56]. Taken together, these findings suggest that neuroinflammation might play a vital role in

the occurrence and development of DM combined with CCH. Consistent with these previous results, in our present study, we found overactivation of microglia and excessive production of pro-inflammatory cytokines in DM/CCH rats. However, curcumin treatment dramatically inhibited neuroinflammation, as indicated by decreased Iba1-positive cells and decreased production of pro-inflammatory cytokines compared to those in DM/CCH rats. Our results *in vitro* also indicated that curcumin reversed high-glucose/hypoxia-induced increases in pro-inflammatory cytokines. CCH causes a cascade of pathological processes in which many different signaling pathways are activated, including the TREM2/TLR4/NF- κ B pathway. TLR4, a classic pattern-recognition receptor, is mainly expressed in microglia and is stimulated by its cognate ligands. Following stimulation, TLR4 further activates the NF- κ B pathway, which plays an important role in the transcription of pro-inflammatory cytokines, including IL-1 β , IL-6, and TNF- α ^[57]. Recently, several studies have demonstrated that TREM2 downregulates TLR4 signaling^[19, 58, 59]. As a membrane-bound receptor mainly expressed in microglia of the central nervous system, TREM2 has been confirmed to regulate the primary functions of microglia, such as inhibiting pro-inflammatory cytokines, promoting phagocytosis, and maintaining the energy metabolism of microglia^[60–62]. A recent study found that lack of TREM2 amplified TLR4-driven inflammatory responses^[63]. Moreover, *in-vivo* studies have demonstrated that TREM2 attenuates neuroinflammation by negatively regulating TLR4-mediated activation of NF- κ B signaling^[43]. In our present study, we found that DM/CCH induced activation of the TLR4/NF- κ B pathway, and unexpectedly also increased the expression of TREM2. This latter finding is contrary to that of some previous studies^[20, 64], perhaps due to different models or different observation times. Interestingly, in our present study, curcumin treatment effectively reversed DM/CCH-induced increase in TLR4 and NF- κ B levels while further increasing TREM2 expression. Our results *in vitro* further confirmed these findings. Recently, Takalo et al discovered that phospholipase C gamma 2 (PLC γ 2) may be associated with TREM2/TLR4 signaling^[65]. They found that PLC γ 2 was activated downstream of TREM2 to promote beneficial microglial function, while PLC γ 2 also acted downstream of the ligand-stimulated TLR pathway to induce inflammatory responses. In the absence of TREM2, microglia are unable to play a protective role in the TREM2/PLC γ 2 pathway and eventually amplify activation of downstream signaling pathways of TLR. However, whether PLC γ 2 is associated with curcumin-mediated regulation of TREM2/TLR4 signaling requires further investigation.

Apoptosis plays a major role in neurological diseases, including AD, PD, and VaD^[22, 66, 67]. Many signaling pathways regulate apoptosis, including Notch, Bax/Bcl2/caspase3, and IRE1- α /TRAF2/ASK1 pathways^[68–70]. Among them, Bax/Bcl2/caspase3 signaling has been extensively studied. Bax is a pro-apoptotic Bcl2-family protein, while Bcl2 is an anti-apoptotic protein^[71]. Additionally, activation of caspase3 is a key event in the execution of DNA fragmentation factor (DFF). The activation of DFF then activates endonucleases, cleaves nuclear DNA, and ultimately leads to cell death. Dysregulation of apoptotic pathways can cause cell death and promote disease progression^[72]. A recent study found that Bax protein expression was increased while Bcl2 expression was decreased in a mouse model of PD^[67]. Consistently, our present results showed that expression levels of cleaved-caspase3 and Bax were significantly increased whereas Bcl2 levels were significantly decreased following DM/CCH *in vivo*,

whereas these changes in expression levels were reversed by curcumin treatment. Similar results were observed in high-glucose/hypoxia-treated microglia *in vitro*. Therefore, our findings suggest that curcumin alleviated DM/CCH-induced and high-glucose/hypoxia-induced pathologies through reducing apoptosis via the Bax/Bcl2/caspase3 pathway.

Recently, inflammasomes have been reported to be associated with the progression of neurodegenerative disorders^[47, 73–75]. Inflammasomes are large polyprotein complexes that mediate the innate immune response to infectious microorganisms. At present, researchers have found a variety of inflammasomes, such as NLRP1, NLRP3, NLRP6, NLRP7, NLRC4, and AIM2^[76]. Among them, the NLRP3 inflammasome is the best characterized and includes a sensor (NLRP3), an adaptor protein (ASC), and an effector protein (caspase1)^[77, 78]. After activation, the NLRP3 inflammasome contributes to the conversion of pro-caspase1 into active caspase1, resulting in the production of proinflammatory cytokines (e.g., IL-18 and IL-1 β), thereby activating NLRP3 signaling that aggravates neuroinflammation and can promote the progression of neurodegenerative diseases^[79, 80]. Additionally, active caspase1 can induce pyroptosis via cleavage of GSDMD. As a protein substrate of caspase1, GSDMD has been identified as a key substrate of the inflammasome proteolytic pathway and the main driver of NLRP3-dependent pyroptosis^[81]. After cleavage of GSDMD, there is an N-terminal cleavage product that remains, which is sufficient to form membranous cores^[82]. Therefore, pyroptosis is distinct from apoptosis since it is characterized by membrane rupture that causes the release of cytosolic contents to further aggravate inflammatory responses. A recent study has found that NLRP3/caspase1/GSDMD signaling is overactivated in PD^[74]. In our present study, we detected the expression of NLRP3-signaling-associated proteins *in vivo* and *in vitro*. Our results *in vivo* showed that curcumin effectively suppressed DM/CCH-induced overexpression of NLRP3, ASC, cleaved-caspase1, IL-18, and cleavage of GSDMD. Similar results were found in microglia exposed to high glucose combined with hypoxia *in vitro*. Taken together, these findings suggest that the beneficial effects of curcumin involve modulation on NLRP3-induced pyroptosis. However, the specific mechanism of curcumin suppressing pyroptosis requires further investigation.

Conclusions

We demonstrated that curcumin attenuated DM/CCH-induced cognitive deficits and hippocampal neuronal damage in rats, and that its underlying mechanisms were associated with inhibiting neuroinflammation, regulating the TREM2/TLR4/NF- κ B pathway, suppressing excessive apoptosis, and mitigating NLRP3-dependent pyroptosis. These findings suggest that curcumin may be useful as a pharmacological strategy for ameliorating DM/CCH-induced memory deficits.

Declarations

8.1. Ethics approval and consent to participate

All the animal experiments were approved by the Institutional Animal Care and Use Committee of Shanghai Jiao Tong University.

8.2. Consent for publication

Written informed consent for publication was obtained from all participants.

8.3. Availability of data and materials

All data generated or analyzed during this work are included in this article.

8.4. Competing interests

The authors declare that they have no competing interests

8.5. Funding

This study was supported by the Project of National Natural Science Foundation of China (No. 81871103, No.81672243). This study was supported by grants-in-aid from Shanghai Municipal Commission of Science and Technology (Grant No.18DZ1160200)

8.6. Authors' contributions

ZYL, ZJW, LY and FJL designed the research. ZYL and ZJW performed the experiments. ZYL, ZJW, ZY and ZYX analyzed the data. ZYL and ZXJ contributed to the production of the manuscript. All authors read

and approved the final manuscript.

8.7. Acknowledgements

We thank Guan Jian for their technical assistance.

Figures

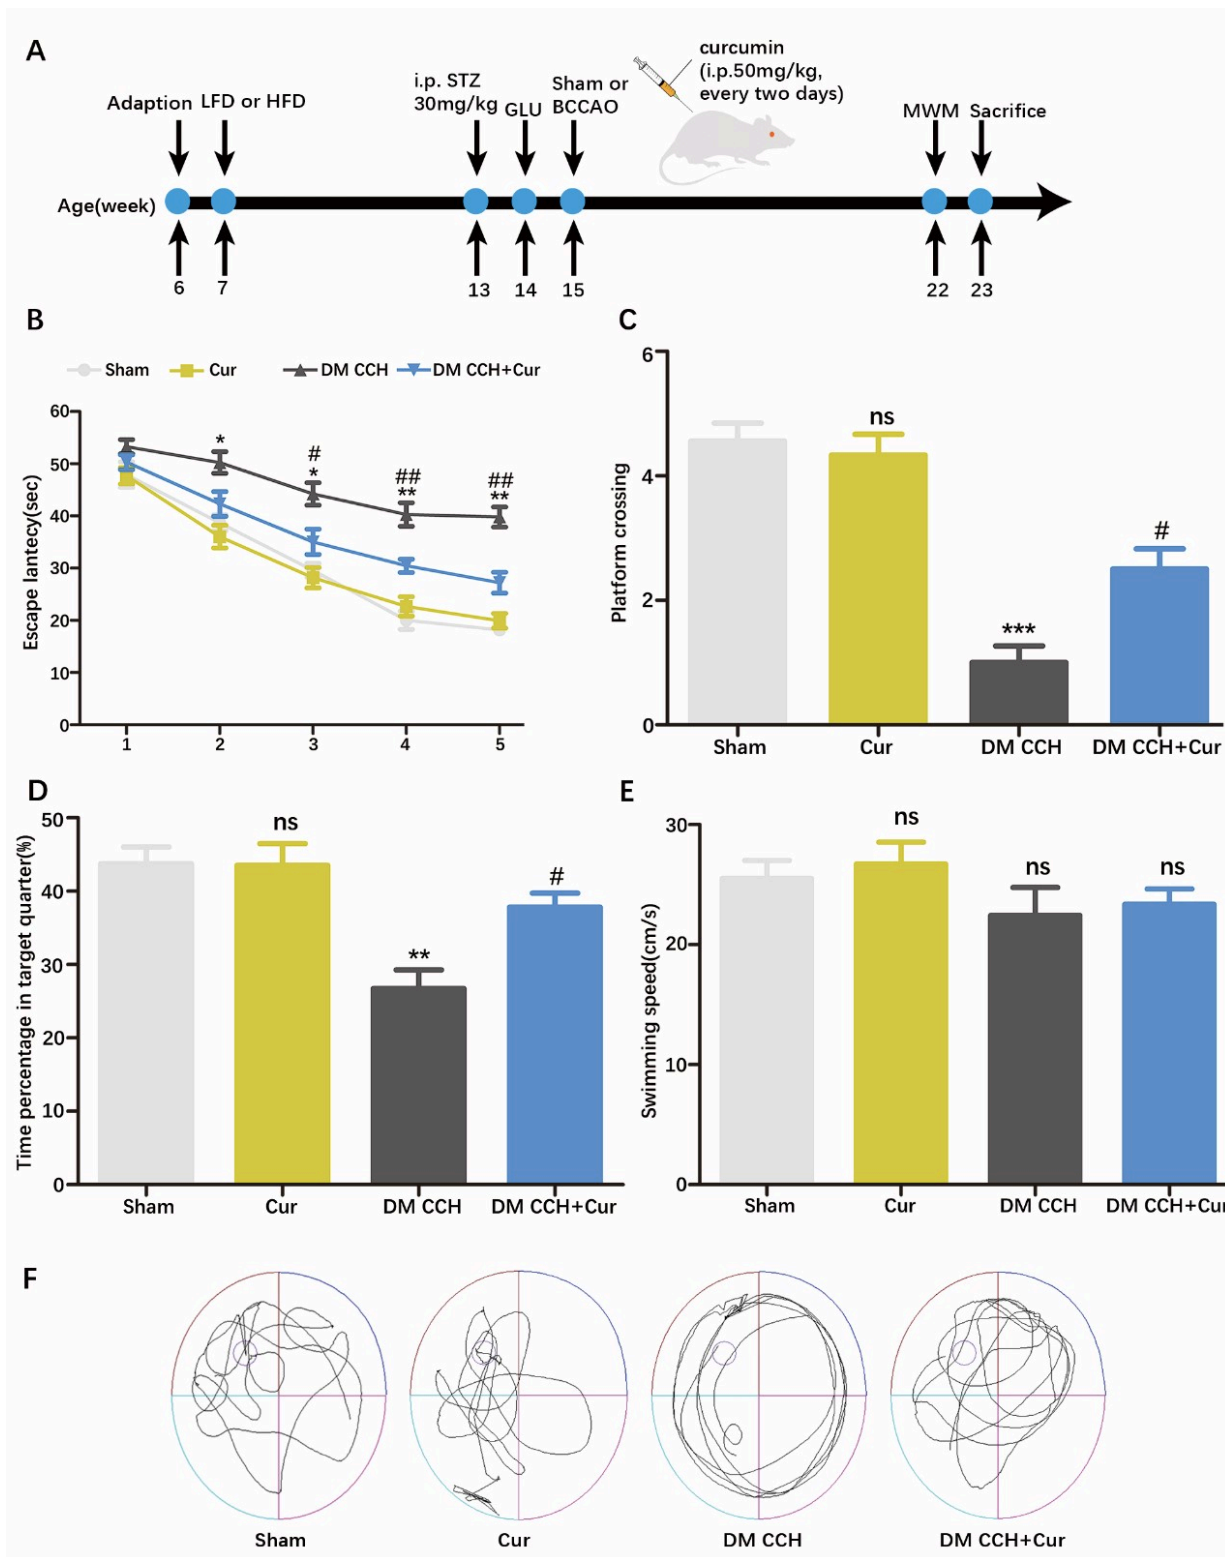

Figure 1

Curcumin alleviates DM/CCH-induced impairments in spatial learning and memory. A Schematic diagram of the experimental scheme of the MWM. B Escape latencies of rats in the hidden platform task. C The number of crossings across the previous location of the platform in the probe test. D Time spent in the target quadrant during the probe trial. E Swimming speed in the probe trial. F Trajectories of rats in

the MWM. Values are expressed as the mean \pm SEM (n = 9/8). *P < 0.05; **P < 0.01, ***P < 0.001 vs. Sham; #P < 0.05; ##P < 0.01 DM/CCH vs. DM/CCH + Cur. Cur, Curcumin

Figure 2

Curcumin attenuates neuronal death in DM/CCH rats. A, B Hippocampal sections of the CA1, CA3, and DG regions were obtained and stained with HE and NeuN (magnification 40 \times or 200 \times , scale bar = 200 μ m)

or 50 μm). Hippo, hippocampus; Cur, Curcumin

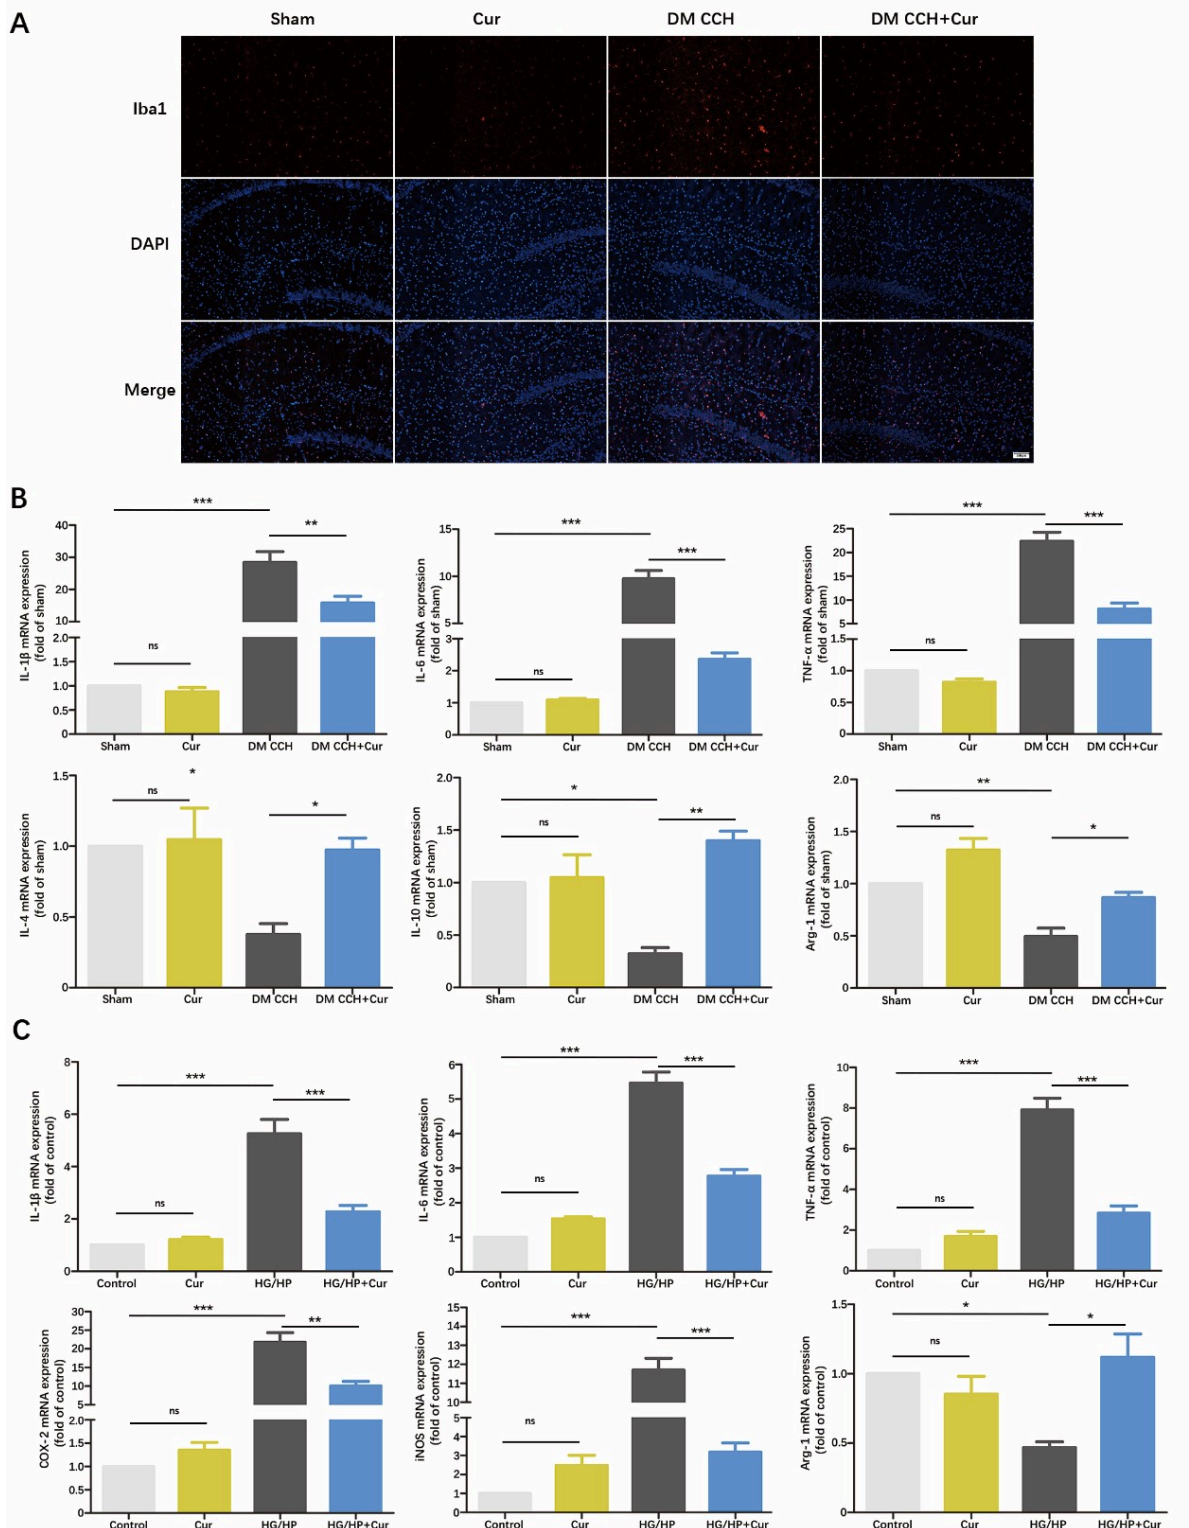

Figure 3

Curcumin inhibits DM/CCH-induced neuroinflammation in the rat hippocampus. A. Representative micrographs showing microglial activation in the CA1 region, using an anti-ionized calcium-binding adaptor protein 1 (Iba1) antibody (red) (magnification 100×, scale bar =100 μm). B, C mRNA levels of pro-inflammatory cytokines (IL-1β, IL-6, TNF-α, iNOS, and COX2) and anti-inflammatory cytokines (IL-4, IL-10, and Arg-1) were detected by qRT-PCR. Cur, Curcumin
