Abstract

Background: Evidence linking homocysteine (Hcy) with cardiovascular diseases (CVD) or its risk factors are insufficient in a Sub-Saharan black population.

Objective: We set out to evaluate the association between Hcy and hypertension and other CVD risk factors in a population of adult Nigerians.

Methods: Data of 156 adults aged 18-70years was accessed from the North Central study site of the REmoving the MAsk on Hypertension (REMAH) study. Homocysteine, blood glucose and lipid profile in whole blood/serum were measured using standard laboratory methods. Hypertension was diagnosed if average of 5 consecutive blood pressure (BP) measurements obtained using a mercury sphygmomanometer was equal to or higher than 140 systolic and/or 90 mmHg diastolic or the individual is on antihypertensive medication. Hyperhomocysteinemia (HHcy) was defined as Hcy>10 μ mol/L.

Results: Of the 156 participants, 72 (43.5%) were hypertensive, of whom 18 had HHcy. Subjects with HHcy were significantly ($p<0.05$) older (41.5 vs 40.6yrs), had lower HDL-cholesterol (0.6 vs 0.8mmol/L) and higher systolic (145.5 vs 126.0mmHg) and diastolic BP (92.9 vs 79.6mmHg), compared to those without HHcy. Intake of alcohol and a 1yr increase in age were respectively and significantly ($p<0.05$) associated with a 1.54 and 0.10 μ mol/L increase in Hcy. In a multivariable model adjusted for age, sex and body mass index, a 1 μ mol/L increase in Hcy, was associated with a 1.69 mmHg and 1.34 mmHg increase in systolic and diastolic pressure ($p< 0.0001$) respectively; and a 0.01mmol/L decrease in HDL-cholesterol ($p<0.05$).

Conclusion: HHcy occurs among hypertensive Nigerians and it is independently associated with age, HDL-cholesterol, systolic and diastolic BP.

Key Words: ■ Hyperhomocysteinemia ■ High-Density Lipoprotein ■ Blood Pressure ■ Cardiovascular Diseases Risk Factors

Introduction

Hypertension is a global health challenge increasingly responsible for most deaths worldwide. According to the Global Disease Burden survey¹, cardiovascular diseases (CVD) account for nearly 17 million deaths annually, of which more than 50% are due to hypertension related complications².

In its effort to tackle the rising burden of hypertension globally, the World Health Organisation recommends increase in physical activity, avoidance of unhealthy diet, reduction in salt intake and abstinence from tobacco use and harmful intake of alcohol. Despite adopting these recommendations at population and individual levels, the burden of hypertension and other CVDs remains inadequately addressed, thus underscoring the need to explore other risk factors such as homocysteine.

Homocysteine is an intermediary metabolite of methionine whose amount in excess of 10 μ mol/L (otherwise known as hyperhomocysteinemia) increases the risk of CVD in people with hypertension³. Compelling evidence from large-scale observational⁴ and longitudinal studies⁵ indicate that the risk of stroke in subjects suffering from hypertension accompanied by HHcy is higher compared to those with neither/either of the two conditions. Epidemiological data from United States of America, China and Europe indicate that among hypertensive subjects, prevalence of HHcy are 39%, 75%, and 19% respectively. Although the role of homocysteine is well-established in the development of vascular diseases^{6,7}, efforts to use it as a therapeutic target of hypertension or CVD has suffered major setbacks^{8,9}. Hypothesis stimulated by recent evidence¹⁰ indicates that the therapeutic benefit of homocysteine lowering may be affected by its interaction with other risk factors of hypertension or CVD, hence may

vary from population to population. ¹¹In Nigeria, 38% of its adult population are hypertensive, of whom control of blood pressure is achieved only in 12% and knowledge of the burden of hyperhomocysteinemia is uncertain. The present study was aimed at evaluating the burden of hyperhomocysteinemia among adult Nigerians and also to assess the relation of homocysteine with hypertension and established risk factors of CVD.

Methods

Participants:

Participants of the current study were of a sub-sample of adult Nigerians aged 18 years and above that participated in the Removing the Mask on Hypertension (REMAH) Study^{11,12}. REMAH was a nationwide study that surveyed hypertension and its risk factors in the six geopolitical zones of Nigeria. From each zone, subjects were drawn from two communities of a state including Anambra, Akwa-Ibom, Oyo, Zamfara, Gombe and FCT-Abuja using a multistaged sampling technique. Communities were sensitized and mobilised, following which houses systematically numbered, randomly selected and visited to issue invitations to eligible adults aged 18 years and above. Physical examinations were conducted on consenting participants further to which blood samples were collected for biochemical examinations. REMAH strictly complied with the Helsinki Guidelines¹³ for conducting research on human subjects. For the purpose of this homocysteine sub-study, a total of 156 subjects with complete data were selected from the FCT-Abuja study site using a systematic random technique. Subjects were excluded if they were on folic acid, vitamin B6, vitamin B12 supplementation or any lipid lowering medications.

Biochemical Examination

Non-fasting blood samples were collected and the resulting sera stored at -20°C until analysis. Homocysteine was estimated from blood serum using the sandwich enzyme-linked immunoabsorbent (ELISA) assay method of Engvall and Perlmann¹⁴. Random blood glucose was measured from whole blood using accucheck glucometer®. Other biochemical analytes including total cholesterol, high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C) and triacylglycerol (TAG) were estimated at the Circulatory Health Research Laboratory using Landwind c100® autochemistry analyser. Analyses were done using ready-to-use reagents obtained from Beijing Strong Biotechnologies incorporation, Haidan District, Beijing China in accordance with manufacturer's guide.

Blood Pressure Measurement: Blood pressure was obtained by trained observers using Accoson® mercury sphygmomanometer. Observers received training on blood pressure measurement using the British Hypertension Society Blood Pressure Measurement Educational Video¹⁵. They measured brachial blood pressure by auscultation of the Korotkoff sounds at the non-dominant arm in accordance with the 2013 guidelines of the European Society of Hypertension(ESH)/European Society of Cardiology (ESC)¹⁶. Participants were allowed to sit and rest for 5 minutes after which 5 BP readings are obtained at an interval of 30 to 60 seconds. Systolic and phase V diastolic blood pressures are determined to the nearest 2 mm Hg. Standard cuffs with 12 x 24 cm inflatable bladders are used for subjects whose arm circumference is less than 31cm, and 15 x 35cm for those with arm circumference greater than 31cm.

A participant's clinic BP was the average of the 5 consecutive BP measurements.

Definition of Terms:

Hypertension was defined according to the 2013 ESH/ESC guidelines¹⁶ as systolic blood pressure \geq 140 mm Hg and/or diastolic blood pressure \geq 90 mm Hg and/or self-reported treatment of hypertension using antihypertensive medications.

Hyperhomocysteinemia was defined according to the American Heart Association/American Stroke Association Council on Stroke as a serum homocysteine greater than 10 μ mol/L¹⁷.

Other measurements: Field officers measured weight and height in Kilogram and centimeter respectively, using a stadiometer. Waist and hip circumference were measured in centimeter using a non-stretchable tape. They also administered a modified WHO STEPs Questionnaire to collect information on relevant medical history, alcohol and cigarette consumption, and intake of medications.

Database management and statistical analysis

We used SAS software version 9.4 (SAS Institute, Cary, NC) for data management and statistical analysis. We used mean and standard deviation to respectively measure the central tendency and dispersion of continuous variables. Differences of means between binary groups were tested using student t-test. We used numbers and percentages to express categorical variables and differences in percentages were tested using chi-square. We regressed serum homocysteine on biochemical, anthropometric, socio-demographic and physiological characteristics to determine their associations. We further tested for Independent association of serum homocysteine with other variables in a multivariable model adjusted for age, sex and BMI. The null hypothesis was rejected for 2-sided values of $P < 0.05$.

Results

Characteristics of Study Participants

Table 1 shows the baseline characteristics of subjects stratified based on their hyperhomocysteinemia status. A total of 156 subjects with an average age of 41.5 years were included in this study. Of the entire subjects, 72 (46.2%) were women, 84(53.9%) were men and 18(11.5%) had hyperhomocysteinemia. In comparison to subjects without hyperhomocysteinemia, subjects with hyperhomocysteinemia had significantly higher ($p<0.05$) mean age (49.0 vs 35.0yrs), higher mean systolic (145.5 vs 126.0mmHg), higher mean diastolic blood pressure (92.9 vs 79.6mmHg) and lower HDL-C (0.6 vs 0.8mmol/L).

Prevalence of Hyperhomocysteinemia

Hyperhomocysteinemia (HHcy) was prevalent in 11.5% of the overall subjects; 13.1% in men, 9.7% in women and 23.6% in subjects with hypertension (Figure 1).

Association of Homocysteine with Sociodemographic Characteristics

According to table 2, homocysteine (Hcy) correlated positively with age and alcohol intake. Intake of alcohol and a 1year increase in age were significantly ($p<0.05$) associated with 1.54 and 0.10 $\mu\text{mol/L}$ increase in Hcy respectively. In a multivariable model, mutually adjusted for age, sex and BMI, the relationship remained the same only for age (Table 3).

Association of Homocysteine with Biochemical Characteristics

A 1 $\mu\text{mol/L}$ increase in Hcy associated positively with triacylglycerol ($\beta=0.03$, $p=0.0252$) and negatively with HDL-C ($\beta=-0.02$, $p=0.0166$). The relationship between Hcy and HDL-C remained the same after adjustment for age, sex and BMI.

Association of Homocysteine with Blood Pressure

Increasing Hcy by 1 $\mu\text{mol/L}$ was associated with a corresponding increase of 2.2mmHg in systolic blood pressure (SBP) and 1.7mmHg in diastolic blood pressure (DBP). Adjustment for age, sex and BMI did not alter the association of Hcy and systolic or diastolic BP.

Discussion

The main finding of this study is that hyperhomocysteinemia (HHcy) occurred in nearly one-eighth of the overall subjects and one-quarter of the hypertensive subjects. Homocysteine (Hcy) independently associated with age, high-density lipoprotein cholesterol (HDL-C), systolic and diastolic blood pressure.

Due to the use of different cut-offs for HHcy in different studies, it is difficult to discuss our findings in the light of those of other studies. Our decision to use the 10 $\mu\text{mol/L}$ threshold was driven by expert opinions¹⁸ which suggest that commencement of Hcy reduction at this level is more beneficial than at higher levels. Previous studies of HHcy among hypertensive Nigerians were hospital-based and were done using a threshold of 15 $\mu\text{mol/L}$. The prevalence of HHcy among hypertensive subjects in the current study (23.6%) was strikingly lower than the ¹⁹56.0% and ²⁰98.3% reported by the previous studies. It is highly probable that difference in study participants may account for this wide difference bearing that subjects of the current study were drawn from a semi-urban general population whose socio-economic status can afford them a vitamin-rich diet well known to protect against HHcy. Vitamin B6, B12 and folic acid are essential requirements of Hcy metabolism which when deficient, precipitates an elevation in plasma Hcy. Other reports across the globe had shown that among hypertensive populations, HHcy occurs 75.0% in China ²¹, 39.4% in the United States of America⁵ and 18.7% in Europe²². In addition to diet, other factors directly influencing plasma Hcy concentration are enzymes responsible for Hcy metabolism such as methylene tetrahydrofolate reductase (MTHFR)²³ and cystathionine beta synthase (CBS)²⁴ whose defective or variant forms could be

involved in geographical/racial with phenotypic variation of HHcy prevalence. In the Hordaland homocysteine study including over 18,000 adult Norwegians aged at least 40 years, low folate status accompanied by Hcy > 40 $\mu\text{mol/L}$ and attributable to the MTHFR 677C > T polymorphism was prevalent in over 78% of the study participants²⁵.

The relation of Hcy with lipid fractions remains largely inconsistent across various observational and experimental studies^{24,26,27}. Nevertheless, some of the earlier results were in concordance with our findings. Evidence from a cross-sectional survey of 4,660 Chinese subjects in Shijingshan district of Beijing, showed that increasing Hcy was associated with an increased risk of low HDL-C (AOR=1.41, 95%CI:1.14-1.73) and hypertriglyceridemia (AOR=1.29, 95%CI: 1.10-1.52). In 300 Indian patients with coronary heart disease, Mahalle and colleagues²⁸ reported that Hcy was directly proportional to TAG and VLDL but inversely proportional to HDL-C. Experimental studies involving the use of double knock-out mice model (CBS $-/-$ /apo-E $-/-$) with reduced CBS activity showed lower HDL-C (19.9mg/dl vs 24.4mg/dl) and higher Hcy (210 μM vs 3.8 μM) when compared with single knock-out (CBS $+/+$ /apo-E $-/-$)²⁴. The mechanism underlying the unfavourable association of Hcy with lipid fractions involves various transcription factors and enzymes of lipid metabolism including peroxisome proliferator-activated receptor alpha (PPAR α), lecithin-cholesterol acyl transferase (LCAT) and sterol regulatory element binding proteins (SREBPs). Hcy interrupts the transcriptional activities of PPAR α , thereby down regulating the production of apo-AI which is an indispensable component of HDL-C production and biological activity²⁹. It is also most probable Hcy interruption/disruption plays some significant roles in the co-regulation of some downstream retrotransposons such as,

transposable elements (TEs), repetitive sequences in mammalian genomes, which have been implicated in many of the same conditions for which PPAR agonists are therapeutic, including conditions such, neurodegeneration, schizophrenia, and drug addiction. Furthermore, Hcy also interferes with HDL-C production by inhibiting the activity of LCAT^{30,31} which is essential for reverse cholesterol transport. Conversely, Hcy enhances the expression of SREBPs, a membrane bound transcriptional factor of the endoplasmic reticulum which encodes enzymes of cholesterol/TAG metabolism and uptake³². These biochemical mechanisms explaining the interaction between Hcy and lipid metabolism are consistent with the results of this study.

Though there are mixed views concerning the link between Hcy and blood pressure^{10,25,33-35}, various mechanisms in support of a positive association have been put forward^{6,36,37}. Under conditions of HHcy, uptake and synthesis of cysteine (an essential precursor of glutathione) is reduced and antioxidant potential compromised thus leading to oxidative stress³⁸. Additionally, Hcy is also metabolised into Hcy-thiolactone, a reactive specie which when bound to collagen, inhibits its activity⁷. The resultant effect of these is endothelial damage, endothelium-myocyte uncoupling, hindered passage of nitric oxide through the matrix barrier, poor vasodilation, diastolic dysfunction and high blood pressure^{6,36}. Other possible mechanisms include increased arterial stiffness, increased arteriolar constriction, increased sodium reabsorption, poor elastic vascular wall and smooth cell proliferation⁶. In a case-controlled study involving 2,615 Chinese subjects, Yang and colleagues¹⁰ observed a strong positive correlation between Hcy and blood pressure ($P < 0.05$). Similarly, report from the third National Health

and Nutrition Examination Survey (NHANES III) including 7,612 United States residents aged 17 and above, showed that after adjusting for CVD risk factors, a 5 μ mol/L increase in Hcy was associated with a 0.7mmHg and 0.5mmHg increase in systolic and diastolic BP in men and a 1.2mmHg and 0.7mmHg increase in systolic and diastolic BP in women³⁹. Contrary to these, the Framingham Heart Survey, documented that after a median follow up 2,104 subjects for 4 years, the age and sex-adjusted odds of hypertension incidence due to Hcy was negative and non-significant³⁴.

Positive association of Hcy with age or alcohol intake have been widely reported^{20,25,27}. Though the mechanism underlying this association is vague, it is hypothesized that deficiency in folate, vitamin B12, metabolic changes, poor nutritional absorption and organ function associated with ageing or alcohol intake are possible causes of this anomaly⁴⁰⁻⁴².

In conclusion, HHcy occurs among adult Nigerians living with hypertension. Hcy associates independently with age, HDL-C, office systolic and diastolic BP. Our findings suggest that Hcy directly or indirect contributes to increasing blood pressure, possibly mediating some of these undesirable effects through disturbance of normal HDL-C and/ or TAG metabolism. These findings also support the need for future research to conduct a pre-assessment of study population with a view to discovering the presence of interaction effects of Hcy and conventional risk factors on hypertension or CVD.

Despite conflicting evidence regarding the CVD benefit of lowering plasma Hcy, which has hindered global adoption of Hcy guidelines in CVD care, routine assessment of Hcy in hypertensive subjects is necessary as emerging evidence⁴³

indicate that Hcy attenuates the efficacy of certain antihypertensive medications like angiotensin converting enzyme inhibitors.

Strengths and Limitations

Given the small size of our sample, caution may be required when translating our findings to the general adult population of Nigeria. However, our subjects were drawn from a well-delineated area of Abuja, a cosmopolitan city with ethnically diverse population that has a semblance of the general Nigerian population. Our study was cross-sectional in design, hence the cause-effect association of Hcy with other factors could not be ascertained.
