## **Keywords:**

ER $\alpha$ , ER $\beta$ , Kelp, Astaxanthin, Saw Palmetto, Tocotrienols, Resveratrol, Curcumin,  
Ashwagandha

## **Abbreviations:**

ER = estrogen receptor, SERM = selective estrogen receptor modulator, TAM = tamoxifen,  
E2 = 17 $\beta$ -estradiol, K=Kelp, Ast=Astaxanthin, SP=Saw Palmetto, T=Tocotrienols, M=Maca,  
H=Horsetail, R=Resveratrol, C= Curcumin, Ash= Ashwagandha, AC=Alternative Curcumin,  
MRR = mitochondrial retrograde response, NAM = nucleus associated mitochondria, ERB-  
041 = ER $\beta$  agonist, PPT = ER $\alpha$  agonist

## **Abstract**

### **Background:**

Hair loss/thinning is a common side effect of tamoxifen in estrogen receptor (ER) positive breast cancer therapy. Some nutraceuticals known to promote hair growth are avoided during breast cancer therapy for fear of phytoestrogenic activity. However, not all botanical ingredients have similarities to estrogens, and in fact, no information exists as to the true interaction of these ingredients with tamoxifen. Therefore, this study sought to ascertain the effect of nutraceuticals (+/- estrogen/tamoxifen), on proliferation of breast cancer cells and the relative expression of ER $\alpha$ / $\beta$ .

### **Methods:**

Kelp, Astaxanthin, Saw Palmetto, Tocotrienols, Maca, Horsetail, Resveratrol, Curcumin and Ashwagandha were assessed on proliferation of MCF7, T-47D and BT483 breast cancer cell lines +/- 17 $\beta$ -estradiol and tamoxifen. Each extract was analysed by high performance liquid chromatography (HPLC) prior to use. Cellular ER $\alpha$  and ER $\beta$  expression was assessed by qRT-PCR and western blot. Changes in the cellular localisation of ER $\alpha$ :ER $\beta$  and their ratio following incubation with the nutraceuticals was confirmed by immunocytochemistry.

### **Results:**

Estradiol stimulated DNA synthesis in three different breast cancer cell lines: MCF-7, T-47D and BT483, which was inhibited by tamoxifen; this was mirrored by a specific ER $\alpha$  agonist in TD47 and BT483 cells. Nutraceuticals did not interfere with tamoxifen inhibition of estrogen; some even induced further inhibition when combined with tamoxifen. The ER $\alpha$ :ER $\beta$  ratio was higher at mRNA and protein level in all cell lines. However, incubation with nutraceuticals induced a shift to higher ER $\beta$  expression and a localization of ERs around the nuclear periphery.

### **Conclusions:**

As ER $\alpha$  is the key driver of estrogen-dependent breast cancer, if nutraceuticals have a higher affinity for ER $\beta$  they may offer a protective effect, particularly if they synergize and augment

the actions of tamoxifen. Since ER $\beta$  is the predominant ER in the hair follicle, further studies confirming whether nutraceuticals can shift the ratio towards ER $\beta$  in hair follicle cells would support a role for them in hair growth. Although more research is needed to assess safety and efficacy, this promising data suggests the potential of nutraceuticals as adjuvant therapy for hair loss in breast cancer patients receiving endocrine therapy.

## Introduction

For women the lifetime risk of developing breast cancer is 1 in 8. Breast cancer is a heterogeneous disease, with several subtypes classified by specific molecular characteristics. Approximately 80% of all breast cancers express the estrogen receptor (ER) [1]. While there are two different nuclear ERs, namely ER $\alpha$  and ER $\beta$ , the principal driver of ER-positive breast cancers is ER $\alpha$ . Tumours positive for ER $\alpha$  comprise two main molecular classifications; luminal A (HER2 negative) with low Ki67 expression, or luminal B, (HER2 positive or negative), with high Ki67 expression. For these subtypes, therapies to block ER $\alpha$  signaling are key to endocrine treatment, hence tamoxifen, an agonist of ER $\alpha$  remains the gold standard treatment [1]. Currently, ER $\beta$  is not a diagnostic marker, or targeted in breast cancer management. However *in vitro* studies point to an inhibitory role for ER $\beta$  in terms of cell proliferation, migration, and invasiveness [2,3], and induction of autophagy [4,5].

Cell lines established from breast tumours, continue to provide the principal experimental model for cancer research, although significant differences exist between *in vitro* cell lines and tissue samples [6]. The MCF7 cell line has been propagated for almost 50 years and used extensively in breast cancer research [7]. It is a luminal A breast cancer cell line, isolated from the pleural effusion of a 69-year-old woman with metastatic disease [8] and is ER and progesterone receptor (PR) positive, and HER2 negative. Similarly, BT483 and T47D are also luminal A, ER and PR positive, HER2 negative cell lines [9]. T47D was established from the pleural effusion of a 54-year-old woman with ductal breast carcinoma

[10], while in contrast, the BT483 line was isolated from a solid, invasive, ductal breast carcinoma of a 23-year-old woman [11]. All three cell lines have been reported to express high levels of ER $\alpha$  protein, while BT483 and T47D also express high levels of prolactin [12]. Endocrine therapy in the form of tamoxifen, which is a selective estrogen receptor modulator (SERM), is prescribed for premenopausal women with ER $\alpha$ -positive breast cancer. Data from the Adjuvant Tamoxifen: Longer Against Shorter (ATLAS) Collaborative Group suggest that 10 years of tamoxifen treatment, as opposed to 5 years, reduces breast cancer mortality by 50% during the second decade after diagnosis [13]. Therefore, many women are prescribed treatment for up to 10 years. Estrogen modulates many non-reproductive tissues, including the hair follicle [14]. However, in women undergoing anti-estrogen treatment, scalp hair loss/thinning is a reported side effect [15,16]. Patterned hair loss comparable to androgenetic alopecia, or male pattern hair loss was reported in a clinical study of 112 women undergoing treatment for breast cancer [17]. A larger study of 19,430 patients with endocrine-related cancers in 35 clinical trials found the highest incidence of alopecia (25.4%) was in women undergoing tamoxifen treatment in a phase II clinical trial [18]. For many women, endocrine therapy induced hair loss is significant, negatively impacting sociocultural status and quality of life. It can lead to non-compliance of therapy and therefore poses a therapeutic challenge in patients with breast cancer.

Nutritional factors play an important role in hair growth and shedding, with current adjuvant therapies for hair thinning encompassing vitamin supplementation e.g., vitamin D, E, C, folic acid [19], or omega-3 fatty acids, which improve hair density, reducing the percentage of resting hair follicles [20]. There is increasing evidence that a plethora of plant-derived nutraceuticals including resveratrol, saw palmetto, maca, curcumin, tocotrienols, ashwagandha, horsetail, astaxanthin, kelp, annurca apple fruits, safflower and ginseng, can have beneficial effects on hair growth [21-24]. Some e.g., saw palmetto are competitive, nonselective inhibitors of 5 $\alpha$ -reductase [25], the key enzyme required in the development of androgenetic alopecia [26]. These polyphenols exhibit anti-inflammatory and antioxidant

activity, and it may be that their mode of action is a protective one, by reducing oxidative stress in the hair follicle.

While nutraceuticals are available without prescription, physicians are often reluctant to endorse them since potential interactions with endocrine therapy has not been fully elucidated. One prospective study suggests antioxidants taken during chemotherapy, as well as iron and vitamin B12, may increase the risk of recurrence (27), yet there are no randomised studies confirming the outcome of antioxidant supplements in breast cancer patients.

However, there are wide-ranging reports that nutraceuticals with beneficial effects on hair growth, including curcumin, tocotrienols, kelp and resveratrol, also exert an anti-proliferative effect on breast cancer cells [23]. Whether this is due to tissue selectivity, e.g., antagonistic SERM in breast cancer cells, or due to a higher affinity for ER $\beta$  remains to be established.

The predominant ER in the human hair follicle is ER $\beta$  [28, 29], while in breast cancer cells it is ER $\alpha$ , therefore the relative expression and affinity for ER $\alpha$  and ER $\beta$  is of significance.

There is some evidence that some plant polyphenol nutraceuticals can downregulate ER $\alpha$  while stabilizing the anti-proliferative ER $\beta$ , resulting in an altered ER $\alpha$ :ER $\beta$  ratio [30].

The most important aspect of supplements that can improve endocrine therapy induced hair loss for women undergoing breast cancer treatment is that they should not mimic the stimulatory effect of estrogen on breast cancer cell proliferation, or that they compete with the antagonistic action of tamoxifen. Therefore, understanding their mechanism of action is key since many women will be prescribed endocrine-directed therapy in the form of tamoxifen. A recent study has correlated breast cancer cell lines with tumours using 4 different molecular datasets, namely, gene expression, copy number variation, DNA exome sequencing mutation, and protein phosphorylation expression, to identify which commonly used cell lines have the highest similarity to breast tumours [9]. By using the total similarity score from these correlations with molecular profiles, this study identified BT483 and T47D as the breast cancer cell lines with the highest similarity to tumours, while MCF7 ranked 17<sup>th</sup>.

Therefore, the aim of this study was to compare the effect of nine different nutraceuticals on the MCF7 ER-positive breast cancer cell line, along with two other ER-positive breast cancer cell lines that display the highest similarity to tumours *in vivo*. Breast cancer cell proliferation was assessed in the presence of each nutraceutical, and compared with the effect of 17 $\beta$ -estradiol, a specific ER $\alpha$  agonist, and a specific ER $\beta$  agonist. Any ability to interfere with the inhibitory effect of tamoxifen on 17 $\beta$ -estradiol-stimulated proliferation in each of the cell lines was also evaluated. In addition, changes in the relative expression and cellular localization of ER $\alpha$  and ER $\beta$  in the presence of the combined nutraceuticals was established in each cell line.

## **Methods**

### **Cell Culture**

The cell lines were obtained from European Collection of Authenticated Cell Cultures (MCF7 and T47D) and American Type Culture Collection (BT483). The cell lines were all routinely cultured in complete RPMI containing 2% FBS (MCF7 and T47D) or 10% FBS (BT483) in a humidified incubator at 37°C, 5% CO<sub>2</sub>.

### **Quantitative RT-PCR**

Triplicate confluent T75 flasks of each cell line were cultured in serum free RPMI for 48h before extraction of RNA using the Aurum™ Total RNA mini kit. RNA was quantified, normalised, and assessed for purity using a NanoPhotometer and cDNA was synthesised using the iScript™ Advanced cDNA Synthesis kit. A mastermix was prepared containing SsoAdvanced™ Universal SYBR® Green Supermix, cDNA and primers (PrimePCR SYBR Green Assay, Desalt 200R, human primers, ESR1 & ESR2 Bio-Rad, UK), before running on a StepOnePlus RT-PCR System (Applied BioSystems, US) under the following conditions: activation (95°C, 2 mins, 1 cycle), denaturation (95°C, 5 secs, 40 cycles), annealing /extension (60°C, 30 secs, 40 cycles), melt curve (65-95°C, 0.5°C increments, 5 secs/step, 1 cycle). Results were calculated as gene expression relative to the RPS18 housekeeping gene, calculated via the  $2^{-\Delta\Delta CT}$  (Livak) method in relation to a positive control primer for the gene of interest. A gDNA primer was also amplified to ensure the samples were free from contamination along with a reverse transcription (RT) control and PCR run efficiency control to ensure the RT and PCR reactions ran appropriately.

### **Western Blot**

Triplicate confluent T75 flasks of each cell line were cultured in serum free RPMI culture medium for 48h before protein extraction with RIPA Buffer, containing complete™ Protease Inhibitor Cocktail Tablets (Roche, UK). Cell lysates were briefly sonicated, centrifuged at 14000 rpm for 1min, the supernatant collected, and protein quantified using the BCA Assay Kit (Pierce, UK). Samples were standardised and diluted in 2x Laemmli Buffer and dH<sub>2</sub>O,

boiled for 5 minutes on a hot block and 30µg loaded onto a precast Any kd gel (Bio-Rad, UK) and SDS-PAGE performed at 120V for 90mins. The protein was transferred to LF-PVDF (Bio-Rad, UK) using the Standard SD program on a Transblot Turbo (Bio-Rad, UK). The LF-PVDF was blocked in 5% BSA/PBS for 90mins before the primary antibodies; mouse anti-estrogen receptor alpha antibody (Bio-Rad, UK) and estrogen receptor beta polyclonal antibody (Thermo Fisher, UK) were added at 1:1000, diluted in 1% BSA/PBS, and incubated overnight at 4°C. Membranes were washed in PBST for 5mins before washing 3X in PBS. Alexa Fluor Donkey Anti Mouse 488/Rabbit 647 secondary antibodies (Invitrogen, UK) were diluted 1:1000 in 1% BSA/PBS. hFAB Rhodamine Anti-GAPDH Primary Antibody (Bio-Rad, UK) was added to the antibody solution at 1:2500 and the membranes incubated in the solution for 90 minutes in the dark, at room temperature on a rocker. Membranes were washed once in PBST then 3X t in PBS and imaged on a Chemidoc MP Imager on 488/555/647 nm channels. Images were quantified using Image Lab.

### **Estrogen agonists and antagonists**

Tamoxifen, 17β-estradiol, were purchased from Sigma UK, and ERB-041 (ERβ agonist) and PPT (ERα agonist) from Tocris UK. They were dissolved in DMSO and diluted in serum free RPMI to their working dilutions tamoxifen (2µM), 17β-estradiol (10nM), ERB-041 (100nM) and PPT (100nM).

### **Extract Origin and Preparation**

Kelp powder extract (*Laminaria Digitata*) was sourced from Iceland (Thorvin, USA); Astaxanthin powder (*Haematococcus pluvialis*, 5% Astaxanthin), was sourced from China; Saw Palmetto powder (*Serenoa Repens Fruit*), was sourced from the USA; Tocotrienols liquid extract (*Elaeis Guineensis Palm Fruit*, 20% tocotrienols), was sourced from Indonesia; Resveratrol powder (*Polygonum Cuspidatum*, Resveratrol 50%), was sourced from China; HorseTail powder (*Equisetum Arvense*), was sourced from China; Ashwaghandha powder (*Withania Somnifera*) was sourced from India; Maca powder (*Lepidium meyenii*) was

sourced from Peru; Curcumin powder (Curcuma Longa Rhizome) and Alternative Curcumin powder (Encapsulated Curcumin, Curcuma Longa Rhizome) were sourced from India. Extracts were dissolved at 100 mg/ml in DMSO by gentle warming and agitation in a ThermoMixer. If the extract did not go into solution fully it was then sonicated, and then passed through a 0.22 µm sterile syringe filter. Extracts were HPLC-MS tested to validate the presence of active ingredients as indicated by manufacturer specification. For combined extract treatments, the top tolerated concentration for each extract, ascertained from the WST-1 cytotoxicity assay (see supplementary Table 1), was combined, and considered 100% for the purposes of further dilutions.

### **WST-1 Cytotoxicity Assay**

Cells were seeded into 96 well microplates at a density of  $5 \times 10^3$  cells/well in and incubated for 24h before incubating with each extract in serum free medium at 100, 50, 10, 1 and 0.1 µg/ml, or 0.1% DMSO (vehicle control) for 48 and 72 hours. Then the medium was removed, and cells were incubated in 100 µl WST-1 (Abcam, UK) diluted 1:10 in serum-free medium for 4 hours before measuring absorbance on a Tecan Infinite plate reader at 450 nm.

### **BrdU Incorporation Proliferation Assay**

Cells were seeded into 96 well microplates at a density of  $7 \times 10^3$  cells/well and incubated for 24h before incubating with extracts diluted in serum free medium, or 0.1% DMSO (vehicle control) for 24h, before 20µl of BrdU reagent (Sigma, UK) was added and they were incubated for a further 24h. The cells were fixed for 30mins using the FixDenat solution provided, before incubating for 90mins with the anti BrdU-POD solution at room temperature. The cells were washed 3X with PBS and once with dH<sub>2</sub>O and incubated with the substrate solution for 30mins before the absorbance was read on a plate reader (Infinite M200, Tecan, Switzerland) at 370 nm.

### **Alamar Blue Proliferation Assay**

Cells were seeded into 96 well microplates at a density of  $5 \times 10^3$  cells/well and incubated for 24h, before incubating with extracts diluted in serum free medium or 0.1% DMSO (vehicle control) for 48h. The medium was removed, and the cells were incubated in 100µl

Alamar Blue (Invitrogen, UK) diluted 1:10 in serum-free medium for 4h in the dark before the fluorescence was read on a Tecan Infinite plate reader at excitation 560 nm, emission 590nm.

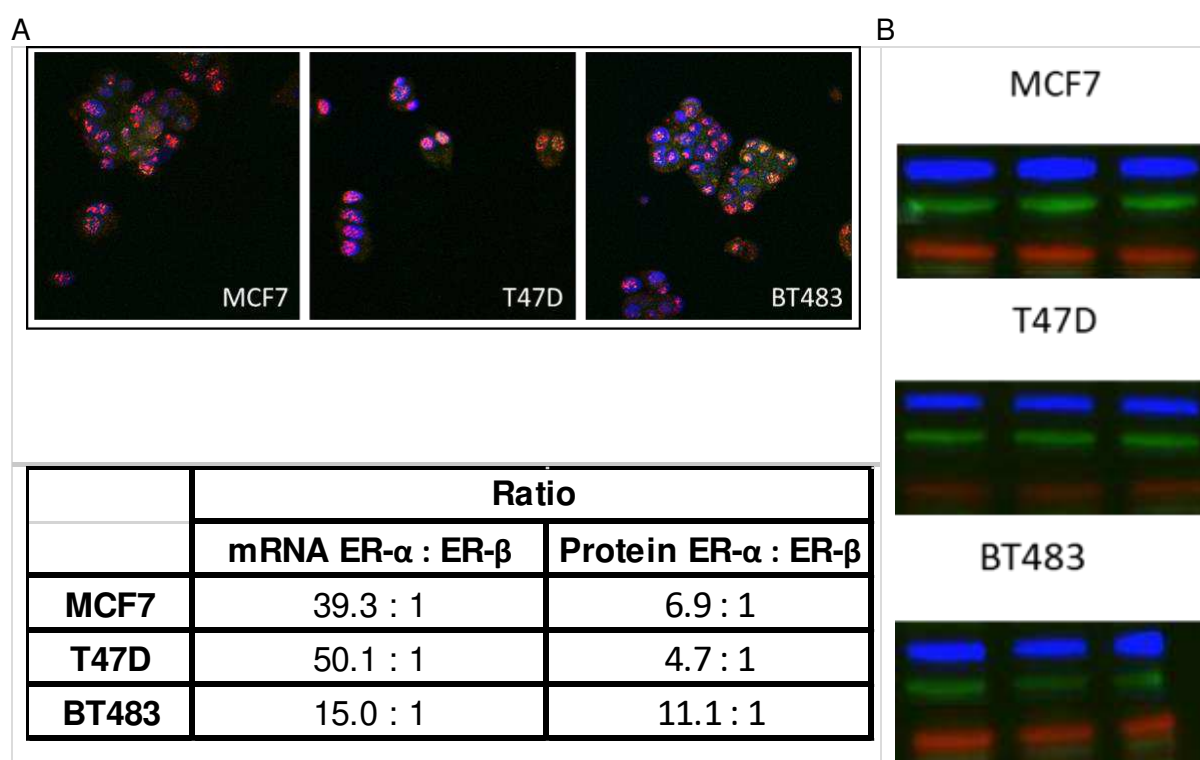

### **Immunocytochemistry**

Cells were seeded into 8 well chamber slides at a density of  $1 \times 10^4$  cells/well and cultured for 24h and then transferred to serum free medium for 48h before fixing in ice-cold methanol for 15 minutes. To assess changes in estrogen receptor expression cells were incubated with the combined extracts diluted in serum free medium for 4h and 24h before fixing. Cells were air dried, blocked with 10% donkey serum in phosphate buffered saline (PBS) for 1h before incubating with the primary antibody recombinant anti-estrogen receptor alpha antibody and anti- estrogen receptor beta antibody (Abcam, UK), both diluted 1:200 in 1% donkey serum, overnight at 4°C. Cells were washed 3X in PBS before incubating with donkey anti-rabbit alexa fluor 488 and donkey anti-mouse alexa fluor 594 (Invitrogen, UK) secondary antibodies, diluted 1:200 in 1% donkey serum at room temperature for 90mins. Cells were washed 3X in PBS before mounting with Vectashield Mounting Medium (Vector Labs, UK). The slides were imaged on a Zeiss LSM 510 Confocal Microscope. 10 images were then quantified using Image J. Nuclei were outlined using thresholding and region of interest (ROI) and the staining intensity quantified in total and within nuclei, on a pixels per cell basis

## Results

### *All cell lines expressed higher levels of ER $\alpha$ compared to ER $\beta$*

All cell lines expressed ER $\alpha$  and ER $\beta$  at the transcript and protein level (Figure 1). However, both mRNA and protein expression of ER $\alpha$  was considerably higher in all three cell lines compared to ER $\beta$ , although the ratio differed between the cell lines. The ER $\alpha$ :ER $\beta$  mRNA ratio was highest in the T-47D cells (50:1) and lowest in BT483 (15:1). The difference in protein levels was not as striking, although ER $\alpha$  was still the predominant receptor. In this instance ER $\alpha$  was more highly expressed in the BT483 cell line (11:1) and the lowest in the T-47D cell line (4.7:1).

**Figure 1.**

**Cellular localization of ER $\alpha$ :ER $\beta$  and quantification of ER $\alpha$ :ER $\beta$  mRNA and protein expression in MCF-7, T47D & BT483 cells**

(A) Immunocytochemistry: ER $\alpha$ =green, ER $\beta$ =red, DAPI=blue, co-localisation = yellow (B) Western blots: ER $\alpha$ =blue, ER $\beta$ =green, GAPDH=red. (C) Quantification of mRNA transcripts by qRT-PCR (n=3 per cell line) and protein expression by quantification of Western blot band density (n=3 per cell line).

### ***Estrogen stimulation of breast cancer cell proliferation is inhibited by tamoxifen***

Incubation with 10nM 17 $\beta$ -estradiol significantly stimulated cell proliferation in all three cell lines. The most responsive was the BT483 cell line (101%,  $p < 0.0001$ ), followed by T-47D (34%,  $p < 0.0001$ ) and then MCF-7 (17%,  $p < 0.0001$ ). Stimulation was inhibited by tamoxifen (2-5 $\mu$ M), and although the degree of inhibition was variable between the three cell lines, proliferation was significantly ( $p < 0.0001$ ) reduced when compared to the effect of 17 $\beta$ -estradiol (Figure 2). In MCF-7 cells, tamoxifen reduced 17 $\beta$ -estradiol stimulation back down to control levels, while only a partial, yet significant, inhibition, was seen in the BT483 cells. Tamoxifen alone appeared to have an inhibitory effect on the T-47D cells. The ER- $\alpha$  agonist stimulated a similar response to 17 $\beta$ -estradiol in T47D and BT483 cells, which was similarly negated by tamoxifen. The ER- $\beta$  agonist had no effect on MCF7 or BT483 cells, although induced a slight stimulation in T47D cells. This was negated in the presence of tamoxifen. Interestingly, tamoxifen in the presence of the ER $\beta$  agonist significantly reduced proliferation to below basal levels in the BT483 cell line (Figure 2). Similar responses were also seen when repeated with the Alamar Blue assay (data not shown).

**Figure 2.**  
**Cell proliferation is stimulated by 17 $\beta$ -estradiol and an ER $\alpha$  agonist which is negated by tamoxifen:**

Incorporation of BrdU by breast cancer cells MCF-7, T47D and BT483 as a percentage of the vehicle control ( $\pm$  SEM of 3 separate assays with 8 experimental replicates). CON = vehicle control (0.1% DMSO); E2 = 17 $\beta$ -estradiol (10nM); TAM = tamoxifen (2 $\mu$ M); PPT (100nM), ERB=ERB-041 (100nM) Cells were incubated for 48 hours. ANOVA (Dunnett's multiple comparison) statistical significance is displayed on the graph above the bars (\* denotes significance vs CON. # denotes significance vs E2.). \* $p \leq 0.05$ , \*\* $p \leq 0.01$ , \*\*\* $p \leq 0.001$ , \*\*\*\* $p \leq 0.0001$ , ns non-significant.

### ***Confirmation of nutraceutical purity and non-toxic concentrations in vitro***

HPLC-MS analysis of the extracts diluted in DMSO confirmed the presence of the active ingredients as indicated by the manufacturer in their specifications (data not shown).

A cytotoxicity dose response assay on each of the three different cell lines confirmed the maximum tolerated dose for each individual nutraceutical (supplementary table 1). All were generally well tolerated by all the cell lines with cytotoxicity only observed at the highest concentrations. The bioavailability and pharmacokinetic data for these extracts is limited. However, all appear to have low bioavailability e.g., a 500mg daily supplement of resveratrol results in plasma levels of 70ng/ml [31] while circulating levels of tocotrienols are approximately 1 µg/l following oral supplementation with 400mg [32]. Therefore, since the highest tolerated dose is likely to be supraphysiological we reduced the dose for both resveratrol and tocotrienol to the nanomolar range of 100ng/ml (0.1 µg/ml), which was 100-fold lower. To be consistent we used a dose of 100-fold lower of the maximum tolerated dose for all the other extracts to avoid using supraphysiological concentrations. The concentrations for each extract are indicated in supplementary table 1 and used for all subsequent assays.

### ***Nutraceuticals did not stimulate breast cancer cell proliferation***

The ability of the following nutraceuticals: kelp, astaxanthin, saw palmetto, tocotrienol, maca, horsetail, resveratrol, curcumin, ashwagandha, alternative curcumin, to stimulate proliferation of all three breast cancer cell lines was assessed either on an individual basis, or in combination; extract 1 (all nutraceuticals except alternative curcumin), extract 2 (all nutraceuticals except curcumin). None of the nutraceuticals stimulated cell proliferation, when assessed by the incorporation of BrdU (figure 3), or with the Alamar Blue assay (data not shown). Alternative Curcumin inhibited DNA synthesis in MCF7 cells, while the combined nutraceuticals inhibited it in BT483 cells,

### Figure 3. Nutraceuticals do not stimulate breast cancer cell proliferation:

Incorporation of BrdU by breast cells MCF7, T47D, BT483 as a percentage of the vehicle control CON = vehicle control (0.1% DMSO), K=Kelp (0.5µg/ml), Ast=Astaxanthin (0.1µg/ml), SP=Saw Palmetto (0.5µg/ml), T=Tocotrienols (0.1µg/ml), M=Maca (1µg/ml), H=Horsetail (1µg/ml), R=Resveratrol (0.1µg/ml), C= Curcumin (0.01µg/ml), Ash= Ashwagandha (1µg/ml), AC=Alternative Curcumin (0.1µg/ml) EXT1=All extracts combined except AC (1%), EXT2=All extracts combined except C (1%). Cells were incubated with the nutraceuticals for 48 hours. ANOVA (Dunnett's multiple comparison) statistical significance is displayed on the graph above the bars (\* denotes significance vs vehicle control.) \*p ≤ 0.05, \*\*p ≤ 0.01, \*\*\*p ≤ 0.001, ns non-significant.

### ***Nutraceuticals did not interfere with the inhibitory effect of tamoxifen on 17β-estradiol stimulated breast cancer cell proliferation***

Nine different nutraceuticals were assessed individually or in combination on their ability to interfere with the tamoxifen inhibition of stimulation by 17β-estradiol, using two different methods for quantifying cell proliferation. The nutraceutical extracts were incubated in combination with 17β-estradiol and tamoxifen for 48h. None interfered with the inhibitory effect of tamoxifen on BrdU incorporation (figure 4). Several further augmented the tamoxifen induced inhibition, although this varied between the different cell lines. In MCF7 cells, kelp, astaxanthin and alternative curcumin acted synergistically with tamoxifen to significantly reduce proliferation compared to tamoxifen alone. Kelp and astaxanthin also had a synergistic effect in T-47D cells, along with saw palmetto, resveratrol, ashwagandha, and curcumin, although alternative-curcumin had no effect. Similar synergy was apparent in

the BT483 cell line, in the presence of kelp, astaxanthin, saw palmetto and alternative curcumin inducing further inhibition in the presence of tamoxifen (figure 4).

**Figure 4. Nutraceuticals do not interfere with the inhibitory effect of tamoxifen on cell proliferation stimulated by 17 $\beta$ -estradiol.** Incorporation of BrdU by breast cancer cells MCF7, T47D and BT483 as a percentage of the vehicle control (+/- SEM of 3 separate assays): CON = vehicle control (0.1%DMSO); E2 = 17 $\beta$ -estradiol (10nM); Tam = tamoxifen (2 $\mu$ M); K=Kelp (0.5 $\mu$ g/ml), Ast=Astaxanthin (0.1 $\mu$ g/ml), SP=Saw Palmetto (0.5 $\mu$ g/ml), T=Tocotrienols (0.1 $\mu$ g/ml), M=Maca (1 $\mu$ g/ml), H=Horsetail (1 $\mu$ g/ml), R=Resveratrol (0.1 $\mu$ g/ml), C= Curcumin (0.01 $\mu$ g/ml), Ash= Ashwagandha (1 $\mu$ g/ml), AC=Alternative Curcumin (0.1 $\mu$ g/ml) EXT1=All extracts combined except AC (1%), EXT2=All extracts combined except C (1%). Cells were incubated with the nutraceuticals for 48 hours in the presence of E2 and tamoxifen. ANOVA (Dunnett's multiple comparison) statistical significance is displayed on the graph above the bars (\* denotes significance vs E2 + TAM. # Denotes significance vs vehicle control. ^ Denotes significance vs E2 treated control). \*p ≤ 0.05, \*\*p ≤ 0.01, \*\*\*p ≤ 0.001.

### ***Nutraceuticals induced a shift in the ratio of ER $\alpha$ :ER $\beta$ in breast cancer cells reducing the relative expression of ER $\alpha$ and increasing the relative expression of ER $\beta$***

Incubation of breast cancer cells with the combined nutraceuticals, except acumin-curcumin (extract 1), induced a shift in the ratio of ER $\alpha$ :ER $\beta$  protein expression in favour of ER $\beta$  (Table 1). The biggest change was in BT483 cells where a concentration of 1% stimulated an increase in the ratio of ER $\beta$  to ER $\alpha$  by 159%. In contrast, incubation with the combined nutraceuticals without biocurcumin (extract 2) only increased the ratio of ER $\beta$  in MCF7 and BT483 cells. In the T47D cells the percentage change in the ratio of ER $\alpha$ :ER $\beta$  favoured an increased expression of ER $\alpha$  (Table 1).

Following incubation for 48h with combined extracts of the nutraceuticals (extract 1 and extract 2), a shift in the cellular localisation of both ERs from a general nuclear/cytoplasmic localisation to a specific area around the periphery of the nucleus was induced (figure 5).

This was observed in all three cell lines but was most prominent in MCF7 cells.

Percentage Reduction in ER $\alpha$ : ER $\beta$	MCF7	T47D	BT483
EXT 1 10%	75.9 %	129.1 %	49.2 %
EXT 1 1%	66.7 %	80.2 %	159.6 %
EXT 2 10%	82.4 %	-29.9 %	54.0 %
EXT 2 1%	72.8 %	-49.9 %	51.2 %

**Table 1. Shift in ratio of ER $\alpha$ :ER $\beta$  in the presence of combined nutraceuticals**

Percentage change in ER $\alpha$ :ER $\beta$  compared to the vehicle control when cells were treated for 48 hours with the combined extracts. The total amount of ER $\alpha$  & ER $\beta$  staining was quantified from randomly selected microscopic fields (n=5) and calculated as total staining present per nuclei. EXT1=All extracts combined except AC, EXT2=All extracts combined except C.

**Figure 5. Cellular localization of ER $\alpha$ :ER $\beta$  in presence of combined nutraceuticals.**

Cellular localization of ER $\alpha$ :ER $\beta$  in presence of combined nutraceuticals. Note the distribution of ERs around the nuclear periphery. Left Panel shows MCF7 cells treated with 10% EXT2, middle panel shows BT483 cells treated with 10% EXT1, right panel shows T47D cells treated with 1% EXT1. ER $\alpha$ =green, ER $\beta$ =red, Magnification = x630.

## Discussion

Cell lines established from breast tumours, continue to provide the principal experimental model for cancer research, although significant differences exist between *in vitro* cell lines and tissue samples [6]. The ER positive MCF7 cell line has been propagated for almost 50 years and used extensively in breast cancer research [7]. A recent study correlating breast cancer cell lines with tumours using molecular datasets, have identified BT483 and T47D as the ER positive cell lines which have the highest similarity to breast tumours [9]. Our study has confirmed that all three cell lines have high ER $\alpha$  and low ER $\beta$  expression, although the ratio varies at both the transcriptome and protein level (figure 1). A previous study also reported much higher expression of ER $\alpha$  compared to ER $\beta$  in MCF7 (93:1) and T47D (23:1) cells by quantifying the proteins via mass spectrometry analysis of 2D-gel spots [33]. This study also compared the proteomic profile of T47D and MCF7 cells, highlighting over 164 proteins were differentially expressed. Proteins with functions in cell proliferation and anti-apoptosis were more highly expressed in T47D cells, while proteins involved in the repression of transcription and regulation of apoptosis were more dominant in MCF7 cells. Such differences further substantiate the heterogeneity of breast cancer and underpin the need to confirm responses in more than one cell line.

In terms of stimulation by 17 $\beta$ -estradiol, the BT483 cell line was the most responsive in our study. Following a 48h incubation with 10nM 17 $\beta$ -estradiol DNA synthesis had increased by 101%, (figure 2). In comparison, the stimulation of T47D and MCF7 cells by 17 $\beta$ -estradiol was more modest at 34% and 17% respectively, which is in line with previous studies [34].

Under basal conditions BT483 cells grow more slowly [12], so the greater response to 17 $\beta$ -estradiol observed in our study may be a result of their higher relative expression of ER $\alpha$  to ER $\beta$  protein. It may also be due having a molecular profile with a much higher similarity to *in vivo* tumours [9]. Many of the commonly used breast cancer cell lines are derived from pleural effusions, including MCF7 and T47D, whereas BT483 is derived from a solid breast carcinoma [11].

Incubation with PPT, which is a selective ER $\alpha$  modulator with no affinity for ER $\beta$  [35] significantly stimulated proliferation of both T47D and BT483 cells (figure 2), although it did not significantly increase MCF7 proliferation. Again, this may reflect the higher response of T47D and BT483 cells to 17 $\beta$ -estradiol and their greater similarity to breast tumours compared to MCF7 cells [9]. Incubation with ERB-104, a preferential modulator of ER $\beta$  with 220-fold selectivity for ER $\beta$  over ER $\alpha$  [36] did not stimulate proliferation of MCF7 or BT483 cells (figure 2), although there was a small stimulation in T47D cells. This may be attributed to ER $\alpha$ :ER $\beta$  expression, particularly since the T47D cells had the highest ratio at the transcriptional level and the lowest ratio at the protein level (figure 1). The concentration of ERB-104 used in the current study was 10-fold higher than that of 17 $\beta$ -estradiol. A study of botanical estrogens with a higher affinity and selectivity for ER $\beta$  reported that at high concentrations they were able to stimulate cell proliferation via ER $\alpha$ , highlighting that their concentration and the cellular ER $\alpha$ :ER $\beta$  ratio significantly modulated their subsequent biological effects [37].

Phytoestrogens share some structural similarities to 17 $\beta$ -estradiol, specifically a phenolic hydroxyl A ring. This structure is paramount for interaction with ER $\alpha$  and ER $\beta$  ligand binding domains, which permits them to simulate the effects of 17 $\beta$ -estradiol [38]. Since they can modulate agonistic or antagonistic responses, such polyphenolic compounds are deemed to be naturally occurring SERMs [39]. However, several studies have shown that phytoestrogens have a higher affinity for ER $\beta$  [40, 41]. To explore the response of human

breast tumours expressing different ratios of ER $\alpha$  and ER $\beta$ , Jiang *et al.* [37], compared their effects on MCF7 cells containing only ER $\alpha$ , only ER $\beta$ , or both ER $\alpha$  and ER $\beta$ . They identified that following preferential binding to ER $\beta$ , phytoestrogens induced co-activator recruitment and stimulated chromatin binding to enhance expression of ER $\beta$ -regulated genes, thereby demonstrating that ER $\alpha$ :ER $\beta$  selectivity and binding affinity of phytoestrogens is augmented at the epigenetic level.

In the current study, none of the nutraceuticals tested, either alone or in combination increased cell proliferation in any of the breast cancer cell lines (figure 3). In MCF7 cells alternative-curcumin inhibited proliferation while the combined nutraceuticals inhibited proliferation in BT483 cells. Of the three breast cancer cell lines examined, BT483 cells have the highest similarity to tumours *in vivo* [9]. In the present study, BT483 had the highest protein expression of ER $\alpha$  in relation to ER $\beta$  than the other cell lines (figure 1).

However, an important question to address with potential SERMs is whether they can they compete with another SERM, in this case tamoxifen. This is of particular significance for women that may be taking even non-phytoestrogenic nutraceuticals to prevent endocrine therapy induced hair loss [23]. Tamoxifen is a non-steroidal triphenylethylene prescribed to pre-menopausal women for the hormonal treatment of ER positive breast cancer. It interacts with both ERs although its affinity for ER $\alpha$  is approximately twice that of ER $\beta$  [42]. However, any competition with binding of tamoxifen to ERs in breast cancer cells would limit its therapeutic capability. Tamoxifen blocked the stimulation of 17 $\beta$ -estradiol-induced proliferation in all three cells lines demonstrating its effectiveness as an estrogen antagonist (figure 4). In MCF7 and T47D cells, tamoxifen reduced 17 $\beta$ -estradiol-induced DNA synthesis back to the basal level, while in BT483 cells, although significantly reduced, it was not fully lowered to basal levels. This is in line with other studies where tamoxifen only partially, but

significantly inhibited the stimulatory effect of 17 $\beta$ -estradiol on breast cancer cell lines, including MCF-7, T47D, ZR-75-1 and BT474 [43].

None of the nutraceuticals interfered with the inhibitory effect of tamoxifen on 17 $\beta$ -estradiol-induced proliferation in any of the cell lines (figure 4). Although variable, several of them further augmented the tamoxifen induced inhibition, reducing proliferation below basal levels indicating a synergistic effect with tamoxifen. Kelp and astaxanthin acted synergistically with tamoxifen to significantly reduce proliferation compared to tamoxifen alone in all three cell lines. Saw palmetto had a synergistic effect in T47D and BT483 cells, while alternative curcumin displayed synergy in MCF7 and BT483 cells, and curcumin in T47D cells. Resveratrol and ashwagandha were also effective in T47D cells (figure 4).

Previously it has been reported that tocotrienols inhibit the proliferation of MCF7 cells, and when combined with tamoxifen reduce proliferation even further [44]. Likewise, while synergy with tamoxifen has not been reported in breast cancer cells, curcumin synergises with tamoxifen in the recovery of H<sub>2</sub>O<sub>2</sub>-induced myocardial apoptosis in ventricular cardiomyocytes of neonatal rats [45]. More recently a study combining novel analogues of resveratrol with tamoxifen demonstrated a synergistic inhibition of the proliferation of breast cancer cell lines, including MCF7 and T47D [46]. Mechanistic studies revealed that in MCF-7 and T47D cells, this synergy was due to down regulation of ER $\alpha$  and the oncogene c-Myc.

Higher expression of ER $\beta$  is associated with improved 5-year disease free survival and overall survival in ER $\alpha$  breast cancer patients [47]. *In vitro* studies have shown that 17 $\beta$ -estradiol-induced T47D proliferation was no longer observed when ER $\beta$  expression was increased, demonstrating that the ability of estrogen-like compounds to stimulate cell proliferation are dependent on the cellular ratio of ER $\alpha$ /ER $\beta$  expression, and whether they have a higher affinity for ER $\alpha$  or ER $\beta$  [35]. In the current study incubation with the combined nutraceuticals induced a shift in the protein expression of ER $\alpha$ /ER $\beta$  in favour of ER $\beta$

(Table1), suggesting that their effect on reducing cell proliferation may be in part, induced by lower ER $\alpha$  and increased ER $\beta$  activity. An interesting observation was the change in the cellular localisation of ERs following incubation with combined nutraceuticals, to a specific area around the periphery of the nucleus (figure 5), which was observed in all three cell lines. Recently it has been demonstrated that cellular redistribution of mitochondria during the mitochondrial retrograde response (MRR) can be facilitated by contact sites with the nucleus; coined nucleus associated mitochondria (NAM) [48]. It has also been reported that mitochondria express ER $\alpha$  and ER $\beta$  that regulate oxidative stress originating in the mitochondria [49]. Furthermore, in MCF-7 cells, tamoxifen activates mitochondrial ER $\beta$  as an antagonist to inactivate manganese superoxide dismutase which upregulates superoxide-induced apoptosis [50]. Further mechanistic studies to determine the impact of nutraceuticals and their combinations on modifying the ER $\alpha$ /ER $\beta$  ratio, and their potential role in regulating mitochondrial function are required.

Many breast cancer patients are prescribed tamoxifen, but this may induce endocrine-therapy induced hair loss, which for many women is an unacceptable side-effect resulting in non-compliance of treatment. Several nutraceutical formulations have shown clinical efficacy in addressing hair loss and as such may be sought out by patients experiencing thinning on tamoxifen. The most important feature of supplements used in endocrine-therapy induced hair loss is that ingredients should not mimic 17 $\beta$ -estrogen or compete with the antagonistic action of tamoxifen. The ideal scenario would be an antagonist in breast cancer cells and an agonist in the hair follicle. ER $\beta$  is the predominant ER in the human hair follicle therefore their potential to shift the ER $\alpha$ /ER $\beta$  ratio in favour of ER $\beta$  in hair follicle cells may be of consequence and warrants further investigation. The hair follicle epidermal matrix cells are the second highest proliferative cells in the human body and susceptible to oxidative stress, therefore the antioxidant mechanism action of these nutraceuticals may also be an important contributing factor to their mechanism of action. While further studies are required to assess

safety and efficacy, this encouraging data supports the safety and potential for use of nutraceuticals as adjuvant therapy for hair loss or thinning in breast cancer patients receiving endocrine therapy.
