Abstract

Background Gram-positive spectrum antibiotics such as vancomycin, teicoplanin, daptomycin ,and linezolid are frequently used in empirical treatment combinations in critically ill patients Although they are included in the national antibiotic restriction program, thought to be inappropriate, unnecessary and suboptimal use is high due to their widespread use. In our study, in addition to their widespread use, gram-positive spectrum antibiotics were evaluated due to their use in more limited and clear clinical indications. This study aims to determine the frequency of inappropriate uses of gram-positive spectrum antibiotics and risk factors for inappropriate use according to different quality parameters.

Methods This clinical study was conducted prospectively between 01.10.2018 and 01.10.2019 in the medical and surgical ICUs of Gazi University Faculty of Medicine Hospital with a total bed capacity of 55. Patients older than 18 years of age onset of gram-positive spectrum antibiotics (vancomycin, teicoplanin, linezolid ,and daptomycin) were included. Patients under the age of eighteen or immunosuppressed (neutropenic, HIV-infected patients with hematologic or solid organ malignancies) were not included in the study. The demographic and clinical features of the patients were recorded. The treatment was also evaluated and recorded by 2 infectious diseases specialists and 2 clinical pharmacists except for the clinical staff at 24-hour intervals from the first day to the last day of treatment. SPSS software for Windows, version 17 (IBM, Armonk, NY) was used to analyze the data. Categorical variables are presented as number and percentage, and non-categorical variables are presented as mean $\pm$ standard deviation.

Results In the use of antibiotics, the incidence of non-compliance with at least one of the determined quality parameters was 83%. Multivariate analysis was performed to evaluate risk factors for inappropriate antibiotic use, and creatine values were found to increase the risk of inappropriate antibiotic use.

Conclusions In spite of the restricted antibiotic program, inappropriate antibiotic use in ICUs is quite common. In particular, it is necessary to establish local guidelines in collaboration with different disciplines for the determination and follow-up of de-escalation and optimal treatment doses
Keywords:Antibiotic stewardship, rational antibiotic use, antibiotic resistance, gram positive microorganism, inappropriate use of antibiotics

1.background

Infection development is an important cause of morbidity and mortality in intensive care units (ICU), leading to the widespread use of antibiotic [1]. It is reported that 41–85% of ICU patients use at least one antibiotic and antibiotic consumption is 10 times higher in ICUs compared to other units [2]. This widespread use increases the unnecessary and inappropriate use of antibiotics and causes an increase in antimicrobial resistance [3]. It is stated that approximately 20–50% of hospitalized patients and 30–60%

of patients in ICU use unnecessary, inappropriate or suboptimal antibiotic treatment [2–5]. Antibiotic stewardship programs are widely used to optimize antibiotic use in hospitals [6, 7].

To develop an effective program, it is necessary to determine the priority targets by evaluating inappropriate antibiotic use [6].

Gram-positive spectrum antibiotics such as vancomycin, teicoplanin, daptomycin, and linezolid are frequently used in empirical treatment combinations in critically ill patients [8]. In our country, after beta-lactams and fluoroquinolones are reported to be the most commonly used antibiotics in ICUs [2]. Although they are included in the national antibiotic restriction program, thought to be inappropriate, unnecessary and suboptimal use is high due to their widespread use. In our study, in addition to their widespread use, gram-positive spectrum antibiotics were evaluated due to their use in more limited and clear clinical indications.

This study aims to determine the frequency of inappropriate uses of gram-positive spectrum antibiotics and risk factors for inappropriate use according to different quality parameters.

2. Methods

This clinical study was conducted prospectively between 01.10.2018 and 01.10.2019 in the medical and surgical ICUs of Gazi University Faculty of Medicine Hospital with a total bed capacity of 55. Patients older than 18 years of age onset of gram-positive spectrum antibiotics (vancomycin, teicoplanin, linezolid, and daptomycin) were included. Patients under the age of eighteen or immunosuppressed (neutropenic, HIV-infected patients with hematologic or solid organ malignancies) were not included in the study.

The demographic and clinical features of the patients were recorded. The treatment was also evaluated and recorded by 2 infectious diseases specialists and 2 clinical pharmacists except for the clinical staff at 24-hour intervals from the first day to the last day of treatment. Demographic data of patients (age, sex, body mass index, etc.), comorbid diseases, Charlson comorbidity indices, indications for antibiotic treatment, presence of sepsis or septic shock, clinical and laboratory findings (microbiological samples and results, creatine values, calculated with Cockcroft formula, GFR) were recorded. This study was approved by the Institutional Review Board of Gazi University School of Medicine and was conducted according to the Helsinki Declaration and good clinical practice. (No:02)

2.a. Definitions

The quality parameters evaluated for inappropriate use in the study are given in Table 1.

Inappropriate antibiotic use; It is defined as non-compliance with at least one of the above quality parameters (Documented antibiotic indication, appropriate microbiological sampling, appropriate dose, de-escalation and duration of treatment).

3. Statistical Method

SPSS software for Windows, version 17 (IBM, Armonk, NY) was used to analyze the data. Categorical variables are presented as number and percentage, and non-categorical variables are presented as mean $\pm$ standard deviation. A Chi-square test was used to compare categorical variables. The suitability of the non-categorical variables to the normal distribution was evaluated by Shapiro - Wilk test. Mann - Whitney U test was used for comparison of non - normally distributed variables and Student -T test was used for comparison of normally distributed variables. In the univariate analysis, variables with a p-value < 0.20 and not correlated with each other were included in the logistic regression model. Charlson comorbidity index, central catheter, treatment approach, CRP, sepsis, procalcitonin ,and creatine levels were included in the logistic regression model. The cases where the type-1 error level is below 5% are statistically significant.

4. Results

During the study, 200 treatments were evaluated in 169 patients. The Clinical features of the patients were evaluated and presented in Table 2.

In the use of antibiotics, the incidence of non-compliance with at least one of the determined quality parameters was 83%. The frequency of inappropriate use of gram-positive spectrum antibiotic was evaluated for each quality parameters and presented in Table 3.

Reasons for inappropriate use of antibiotics were evaluated and presented in Fig. 1.

Risk factors for inappropriate use of antibiotics were analyzed and presented in Table 4.

Multivariate analysis was performed to evaluate risk factors for inappropriate antibiotic use, and creatine values were found to increase the risk of inappropriate antibiotic use (Table 5).

5. Discussion

In this study, 83% of the gram-positive spectrum antibiotics used in ICUs were found to be inappropriate. Compliance with the evaluation of de-escalation was very low in our ICUs. Renal failure was caused inappropriate use and increased the frequency of inappropriate use of antibiotics by about 2-fold.

In Turkey, 71.3% of patients in the ICU are treated with antibiotics[2]. This widespread using leads to unnecessary and inappropriate use. It is recommended to use different quality parameters to evaluate inappropriate antibiotics used. Dresser et al. recommend that uncertainty of indication, the continuation of empirical treatment without evidence of infection, and the presence of unnecessary prophylaxis and drug contraindications as quality criteria for the evaluation of inappropriate antibiotic use [9]. For the same evaluation, Kallen et al. recommend that appropriate microbiological sampling, therapeutic drug monitoring for vancomycin and aminoglycoside, taking surveillance cultures and periodically sharing

local resistance data [1]. The incidence of inappropriate empirical antibiotic use in ICUs varies between 14.1–78.9% due to differences in evaluation criteria [4, 20]. In Turkey, this incidence ranges from 30% to 50%. [21–23]. Our incidence of inappropriate antibiotic use was found to be high compared with the literature [6]. This is thought to be related to the evaluation of different clinical indications and the evaluation of empirical treatments as well as the agents' specific treatment processes.

Since 2003, a national antibiotic restriction program has been implemented in Turkey. Previous studies have been shown that these programs reduce nosocomial infection, length of hospital stay, mortality and microbial resistance rates. They have a positive effect on health expenditures [3, 24, 25]. However, several studies were shown that increased prescriptions of non-restricted antibiotics may be eliminated these positive effects [2, 3]. In our study, it was shown that antibiotics, all of which are under a restricted antibiotic program, are used inappropriately with high frequency. This indicates that inappropriate antibiotic use in ICUs can not be prevented by restriction programs alone and that the system should be supported by audit and feedback mechanisms. The results of an intervention study conducted by Güçlü et al. was shown that antibiotic restriction programs can be activated by supporting prospective control and feedback mechanisms [3].

In our study, the most common reason for inappropriateness was the continuation of antibiotics without microbiological evidence. In ICU, the de-escalation algorithm reduces the duration of treatment and the frequency of microbial resistance without increasing mortality [3, 26–28]. In studies conducted in Turkey, it is stated that the necessity of de-escalation was 10% [23]. On the other hand, the necessity of de-escalation in ICUs was shown to be higher. Mutters et al study was shown that compliance with the evaluation of therapy discontinuation or de-escalation was 2.4-8% [29]. In our study, the compliance of the early period (3 days) de-escalation was found to be quite low. The frequency of de-escalation was found to be slightly higher in the late period (5 days). Considering the high frequency of appropriate microbiological sampling, this may be related to late results of blood culture due to the long incubation period. Despite the increase compared to the early period, the frequency of late de-escalation was found to be low. The most important reason for this is thought to be the unwillingness of clinicians to discontinue treatment despite the culture results. It appears that the restricted antibacterial program alone does not seem to be sufficient for proper de-escalation in ICUs. There is a need to develop an effective de-escalation strategy supported by local treatment guides.

Another important reason for inappropriateness in our study was the lack of proper antibiotic dose adjustment according to the glomerular filtration rate. Renal failure and renal replacement therapies cause plasma concentration changes and affect drug concentrations [5]. Renal replacement therapies (RRT), especially continuous RRT, have also been shown to cause significant pharmacokinetic changes on the antibiotic groups we evaluated [30–32]. Therefore, antibiotic doses may remain suboptimal in ICU patients when compared to the normal population. [5, 33, 34]. In our study, the frequency of RRT was 21.7%. And also, 6.7% of all patients received continuous RRT during the study. Also, elevation in serum level was found to be the determining major risk factor for the inappropriate use of antibiotics. Therefore, creatine clearance changes need to be periodically evaluated to determine appropriate doses of

antibiotics in collaboration with clinical pharmacists, infectious diseases specialists and clinical staff in ICUs [5].

Single-centered and evaluation of antibiotics with only gram positive effects are limitations of this study.

6.conclusion

In spite of the restricted antibiotic program, inappropriate antibiotic use in ICUs is quite common. Appropriate use of antibiotics should be audited with predetermined quality parameters. In particular, it is necessary to establish local guidelines in collaboration with different disciplines for the determination and follow-up of de-escalation and optimal treatment doses. In patients undergoing renal replacement therapy with increased risk of suboptimal concentration, antibacterial treatment doses should be individualized and closely monitored.

Declarations

Ethics approval and consent to participate

This study was approved by the Institutional Review Board of Gazi University School of Medicine, Ankara/Turkey and was conducted according to the Helsinki Declaration and good clinical practice. (No:02/14.01.2019). Written informed consent was obtained from adults (> 18 years old).

Consent for publication

Not applicable.

Availability of data and materials

All data generated or analysed during this study are included in this published article.

Competing interests

The authors declare that they have no competing interests.

Funding

The funding body had no role in the study design, analysis and interpretation of results nor in writing the manuscript.

Authors' contributions

HSO and KH designed the study, DMF KE and AA collected datas, HSO interpreted the results, and wrote the manuscript. All of writers read and approved the final manuscript.

Acknowledgements

We would like to thank both reviewers of this article for valuable suggestions.

CRP, mean $\pm$ SD	133 $\pm$ 92.8	156 $\pm$ 112	.041
Procalcitonin, mean $\pm$ SD	18.7 $\pm$ 85.5	14.9 $\pm$ 68.5	.013

Abbreviations; SD, standart deviation; BMI, Body mass index; CCI, Charslon comorbidity index; ICU, Intensive care unit; WBC, White blood cell; PLT; Platelet; GFR, Glomerular filtration rate; Cr, Creatinine, CRP, C-reactive protein

Table 5. Risk Factors for Inappropriate Antibiotic Use in Multivariate Analysis

	B	S.E	Sig.	O.R	% 95 C.I
CCI	-.042	.093	.650	.959	.799-1.150
Sepsis	-.552	.776	.477	.576	.126-2.635
Antibiotic tretament approach	-.504	.442	.255	.604	.254-1.438
Central venous catheter	.322	.415	.438	1.380	.612-3.112
CRP	-.003	.002	.136	.997	.993-1.001
Prokalsitonin	.000	.002	.889	1.00	.995-1.005
Creatinine	.685	.258	.008	1.985	1.196-3.292

Abbreviations: B, unstandardized regression weight; CI, confidence interval; OR, odds ratio; SE, standard error; CCI, Charslon comorbidity index; CRP,C-reactive protein
