Abstract

Background: Although the influenza vaccine has been proven to be effective, this common disease has high morbidity and mortality rates. Moreover, adults with diabetes are at a high risk of influenza-mediated morbidity and mortality. With the increasing prevalence of diabetes and the efficacy of vaccination in preventing influenza, the aim of this study was to investigate the factors associated with influenza vaccination coverage in patients with diabetes.

Methods: Cross-sectional data were obtained from the Korea National Health and Nutrition Examination Survey (2016–2018). We analyzed whether sociodemographic, health-related, and medical factors are associated with influenza vaccination coverage in patients with diabetes. A complex sample logistic regression analysis was performed and odds ratios (ORs) were estimated by adjusting for statistically significant factors.

Results: The number of survey subjects was 18553. The vaccination coverage rate among patients with diabetes was 60.6%. In the univariate analysis, gender, educational level, smoking, exercise, drinking, marital status, private health insurance, activity limit, economic activity, age, and EuroQol-5 Dimension scores were associated with vaccination coverage. In the multivariate analysis, only age and economic activity were associated with vaccination coverage. The vaccination coverage rate was higher for people who did not undertake economic activities and who were older (OR 1.512 (1.087–2.105), OR 2.212 (1.822–2.686), respectively, $p < 0.001$).

Conclusions: National interventions involving public health centers are necessary to encourage influenza immunization for patients with diabetes, especially younger patients and those who are working or undertaking economic activities.

1. Background

Despite the proven effectiveness of the influenza vaccine, this common disease still has high morbidity and mortality rates [1]. Vaccination is the most cost-effective way of reducing the risk of influenza and its complications, especially in older adults and patients with chronic diseases [1–3]. Seasonal influenza pandemics are disastrous for public health, especially during winter [1]. Further, adults with diabetes are at a high risk of influenza-mediated morbidity and mortality [4, 5]. A recent study of morbidity and mortality among patients with coronavirus disease 2019 (COVID-19) found that the disease is more severe in patients with diabetes [6, 7]. Among the fatalities caused by COVID-19, research demonstrates that diabetes was the second-most common comorbidity after hypertension [7]. Indeed, diabetes has been found to increase patient vulnerability in all viral diseases.

In a Canadian study, patients with diabetes, even those aged under 65 years, were found to be susceptible to influenza and had higher rates of influenza-attributable all-cause hospitalization [4]. The reason for the increased vulnerability to influenza in patients with diabetes is their impaired immune response; they have abnormal CD4/CD8 ratios, and their natural killer cells and monocytes do not function well [8, 9].

For effective prevention against influenza, the World Health Organization (WHO) recommends a vaccination coverage rate (VCR) of at least 75% in vulnerable populations [10]. However, recent data demonstrate that the recommended influenza VCR is not being achieved in most countries [11–13].

In 2011, 366 million patients worldwide were recorded as having diabetes, and according to the International Diabetes Federation, this number is expected to increase by 50% by 2030 [14]. As the prevalence of diabetes increases and people with diabetes remain vulnerable to infection [15, 16], it is important to examine the influenza VCR in this population. In South Korea, national support for the influenza VCR is very high, and it contributes to various indicators, including influenza-related outpatient consultations, hospitalization and excess mortality, quality-adjusted life years, and the incremental cost-effectiveness ratio [17].

Despite this support for the influenza VCR and the existence of related research in South Korea, existing studies have focused only on chronic obstructive pulmonary disease [18], other chronic diseases [19, 20], or older adults [21–23]. Thus, the aim of this study is to evaluate the socioeconomic, personal, and environmental factors associated with the influenza VCR among people with diabetes, who are very vulnerable to infection.

2. Methods

2.1. Data source

This study was conducted using cross-sectional data obtained from the 2016–2018 Korea National Health and Nutrition Examination Survey (KNHANES). The KNHANES is annually conducted to assess the health and nutritional status of the non-institutionalized civilian population in South Korea. These investigations, which include a health interview survey, a health examination survey, and a nutrition survey, are conducted by trained investigators. In the present study, a clustered and stratified random sampling method based on national census data was used. Participants below the age of 19, as well as those who did not faithfully complete the test, were excluded from the study.

Further, diabetes was the only disease included in the survey; all other chronic diseases, such as cardiovascular disease, respiratory disease, liver disease, and cancer, were excluded.

2.2. Ethical considerations

The study was approved by the Clinical Trial Screening Committee of W Hospital, and the requirement of informed consent was waived (institutional review board approval number: 2020-03-013). Detailed information on the KNHANES is available for reference on the website [24]. The present study complies with the principles laid down in the amended Declaration of Helsinki.

2.3. Sociodemographic factors

The following sociodemographic factors were considered: age, gender, educational level, economic activity, marital status, and cohabitation status. Educational level was classified into four groups: elementary school graduates, middle school graduates, high school graduates, and university graduates. Marital status was divided into two groups: married and unmarried. Cohabitation status was divided into four groups: cohabiting, separated, bereaved, and divorced. Non-employment was divided into two groups: unemployed and non-economically active.

2.4. Health behavior and medical factors

Subjective health status and disease were investigated as medical factors. Subjective health status was classified into five groups: very good, good, average, bad, and very bad. The participants' usually perceived level of stress was investigated through the following statements: 1) "I feel a great deal of stress," 2) "I feel much stress," 3) "I feel a little stress," 4) "I hardly feel stress," 5) "Not applicable," and 6) "Unknown."

Choosing statement 1 or 2 indicated that participants experienced much stress, while choosing statement 3 or 4 indicated that they experienced less stress. A stress-sensitive participant was marked 1, and a less stress-sensitive participant was marked 0. The average value was recorded as the stress recognition rate.

The EuroQol-5 Dimension (EQ-5D) is a comprehensive index used to assess health-related quality of life (HRQoL) through five dimensions: exercise ability, self-management, daily activities, pain/discomfort, and anxiety/depression. The closer the score is to 1, the higher the HRQoL [25].

Regarding smoking status, participants were classified as either smokers or non-smokers. People who smoked at the time of data collection or had smoked more than 100 cigarettes throughout their lives were defined as smokers. Alcohol consumption was investigated by calculating the amount of alcohol consumed by a participant per week in grams. The International Physical Activity Questionnaire was used to measure the extent of physical exercise; "regular exercise" was defined as exercising at least five times a week for 30 minutes per session, or participation in vigorous physical activity three times a week for more than 20 minutes per session.

The participants' blood samples were randomly collected after an eight-hour fast and subjected to laboratory testing. The samples were immediately processed, refrigerated, and transported to the central laboratory (Neodin Medical Institute, Seoul, South Korea).

2.5. Statistical analysis

SPSS for Windows version 21.0 (IBM Corp., Armonk, NY, USA) was used for statistical analysis, and statistical significance was set at $p < 0.05$. Owing to the complexity of KNHANES data, a complex sample analysis was conducted considering weights. Weights were applied according to the Centers for Disease Control and Prevention's guidelines for using KNHANES raw data.

For the overall results, a frequency analysis was performed using the Complex Samples Frequencies procedure. The complex sample Rao-Scott adjusted chi-square test and complex sample generalized

linear model were used to compare differences in the general characteristics of patients with and without diabetes. A complex sample logistic regression test was used to analyze the factors associated with influenza vaccination among patients with diabetes.

3. Results

3.1. General characteristics and diabetes prevalence (Table 1)

There were two groups—patients with and without diabetes. Among patients with diabetes, there were more people with an educational level of primary school or lower than those who had a college degree or higher (36% vs. 15%). Further, in this group, 18.3% were smokers, 33.4% engaged in aerobic exercise, and 44.3% drank monthly. The average stress perception rate was 23.5%, 96.6% were married, 72.1% were living with someone, 58.6% had private health insurance, and 16% performed limited physical activity. When evaluating their subjective health, the proportions of participants with diabetes who answered “very good” (1.4%) and “good” (10.8%) were low. Further, 46.9% were not employed and had lower EQ-5D scores than people not living with diabetes (0.90 ± 0.004 vs. 0.96 ± 0.001 ; $p < 0.0001$).

Table 1
General characteristics and diabetes prevalence

		N = 18553	Normal	Diabetes	p-value
Gender	Men	8127 (49.8)	7240 (49.6)	885 (52.3)	0.058
	Women	10426 (50.2)	9496 (50.4)	924 (47.7)	
Educational level	≤ Elementary school	3656 (13.9)	2907 (12.1)	749 (36)	< 0.0001
	Middle school	1782 (8.3)	1490 (7.7)	292 (15.7)	
	High school	5617 (33.2)	5184 (33.7)	433 (27.4)	
	≥ College	6530 (39.1)	6296 (41.1)	234 (15)	
Smoking		3338 (21.3)	3044 (21.6)	293 (18.3)	< 0.0001
Exercise		7554 (43.8)	7008 (44.6)	546 (33.4)	< 0.0001
Drinking		9888 (58.1)	9158 (59.2)	729 (44.3)	< 0.0001
Stress recognition		4903 (28.1)	4503 (28.5)	398 (23.5)	< 0.0001
Marital status	Married	15477 (76.8)	13708 (75.1)	1761 (96.6)	< 0.0001

Cohabitation status	Cohabiting	12837 (65.6)	11560 (65.1)	1271 (72.1)	< 0.0001
	Separated	116 (0.6)	100 (0.5)	16 (0.9)	
	Bereaved	1705 (6.6)	1333 (5.6)	371 (18.4)	
	Divorced	812 (3.9)	708 (3.8)	103 (5.3)	
Private health insurance		14172 (80.7)	13227 (82.6)	944 (58.6)	< 0.0001
Activity limit		1514 (6.5)	1211 (5.8)	303 (16)	< 0.0001
Subjective health	Very good	799 (4.5)	774 (4.7)	25 (1.4)	< 0.0001

		N = 18553	Normal	Diabetes	p-value
	Good	4164 (23.9)	3962 (25)	201 (10.8)	
	Average	9203 (49.6)	8402 (50)	801 (45.5)	
	Bad	2769 (14)	2290 (12.9)	479 (26.7)	
	Very bad	765 (3.1)	9 (16.1)	216 (10.7)	
Economic activity	Employed	10677 (61.1)	9906 (62.3)	771 (47.3)	< 0.0001
	Non-employed	6918 (33.5)	5980 (32.4)	938 (46.9)	
Influenza vaccination	Yes	7750 (35.4)	6557 (33.3)	1193 (60.6)	< 0.0001
	No	9900 (59.5)	9373 (61.6)	527 (34.1)	
Frequency of vaccination	1	7675 (35.1)	6493 (33)	1182 (60.1)	< 0.0001
	2	75 (0.3)	64 (0.3)	11 (0.5)	
Place of vaccination	Public health center	2239 (24.5)	1796 (23)	443 (34.9)	< 0.0001
	Hospital,	5210 (70.4)	4484 (71.6)	726 (62.8)	
	Others	295 (5.0)	272 (5.4)	23 (2.2)	
Age, years		40.87 ± 0.27	45.89 ± 0.23	63.60 ± 0.36	< 0.0001
EQ-5D		0.95 ± 0.001	0.96 ± 0.001	0.90 ± 0.004	< 0.0001
HbA1c		5.61 ± 0.008	5.51 ± 0.01	7.21 ± 0.04	< 0.0001

Smoking: the percentage of people who had smoked more than five packets of cigarettes (100 cigarettes) in their lifetime or who smoked at the time of the survey; alcohol: percentage of participants who had an alcohol intake of more than once a month in the last year; non-employed: unemployed and non-economically active population; stress: percentage of stress in everyday life; EQ-5D: EuroQol-5 Dimension; HbA1c: hemoglobin A1c.

Values are presented as number (%) or mean \pm standard deviation.

^a The *p*-value was calculated using the complex sample Rao-Scott adjusted chi-square test and complex sample generalized linear model t-test.

People with diabetes had higher influenza VCRs compared with those who did not have diabetes (60.6% vs. 34.1%). People with diabetes were rarely inoculated twice a year and were more likely to be vaccinated in hospitals or clinics than in public health centers (62.8% vs. 34.9%; $p < 0.0001$).

3.2. Factors associated with influenza vaccination among people with diabetes (Table 2)

A single analysis of factors associated with influenza vaccination among people with diabetes revealed that women had higher VCRs than men. Further, those with an educational level of primary school or lower had higher VCRs than those who had obtained a college degree or higher (odds ratio (OR) 1.928 (1.516–2.452), OR 4.215 (2.905–6.116), respectively; $p < 0.001$).

VCRs were higher among non-smokers, those who did not practice aerobic exercise, and those who were not monthly drinkers (OR 2.437 (1.766–3.363), OR 1.339 (1.034–1.734), OR 2.180 (1.689–2.814), respectively; $p < 0.001$).

VCRs were low among unmarried participants and high among non-private health subscribers (OR 0.184 (0.081–0.418), OR 2.984 (2.323–3.835), respectively; $p < 0.001$). VCRs were also higher among those with limited physical activity and those who were not employed (OR 1.471 (1.048–2.065), OR 3.236 (2.473–4.235), respectively; $p < 0.001$).

The VCR increased as participants' age increased by 10 years, and as the EQ-5D score decreased by 1 (OR 2.586 (2.208–3.028), OR 10.939 (3.961–30.207), respectively; $p < 0.001$).

A multivariate analysis of the factors associated with influenza vaccination among people with diabetes demonstrated that VCRs were higher among those who were not employed, and that VCRs increased with age (OR 1.512 (1.087–2.105), OR 2.212 (1.822–2.686), respectively; $p < 0.001$).

Table 2
Factors associated with influenza vaccination among people with diabetes

		Univariate	Multivariate
		OR (95% CI)	OR (95% CI)
Gender	Men	1	1
	Women	1.928 (1.516–2.452)	1.095 (0.79–1.519)
Educational level	≤ Elementary	4.215 (2.905–6.116)	1.266 (0.785–2.042)
	Middle	2.406 (1.548–3.739)	1.462 (0.88–2.429)
	High	1.409 (0.947–2.096)	1.225 (0.766–1.961)
	≥ College	1	1
Smoking	No	2.437 (1.766–3.363)	1.319 (0.902–1.930)
Exercise	No	1.339 (1.034–1.734)	0.822 (0.607–1.112)
Drinking	No	2.180 (1.689–2.814)	1.134 (0.826–1.558)
Marital status	Married	1	1
	Single	0.184 (0.081–0.418)	0.566 (0.193–1.659)
Private health insurance	No	2.984 (2.323–3.835)	1.061 (0.774–1.456)
Activity limit	Yes	1.471 (1.048–2.065)	0.821 (0.531–1.271)
Economic activity	Employed	1	1
	Non-employed	3.236 (2.473–4.235)	1.512 (1.087–2.105)
Age	10-year increase	2.586 (2.208–3.028)	2.212 (1.822–2.686)
EQ-5D	-1	10.939 (3.961–30.207)	1.08 (0.365–3.193)

OR: odds ratio, CI: confidence interval.

Smoking: the percentage of people who had smoked more than five packets of cigarettes (100 cigarettes) in their lifetime or who smoked at the time of the survey; alcohol: percentage of participants who had an alcohol intake of more than once a month in the last year; non-employed: unemployed and non-economically active population; EQ-5D, EuroQol-5 Dimension.

Adjusted for gender, age, educational level, smoking, exercise, drinking, marital status, private health insurance, activity limit, economic activity, age, EQ-5D score.

^a OR and 95% CI were calculated using a complex sample logistic regression test.

4. Discussion

As previously discussed, people with diabetes are especially vulnerable to all infectious diseases, including influenza. Recently, people with diabetes were reported to have the second-highest mortality risk from COVID-19. Before highlighting the need for vaccination, however, it is necessary to evaluate the factors associated with the influenza VCR among people with diabetes. Previous South Korean studies that investigated the influenza VCR and associated factors have focused either on the general population [26, 27] or those with other chronic diseases [19, 20].

As people with diabetes are more susceptible to influenza and have a greater risk of medical complications from infection, the WHO and several National Immunization Technical Advisory Groups recommend annual influenza vaccination [28, 29].

A systematic review and meta-analysis of people with diabetes demonstrated that the effectiveness of the influenza vaccine differs slightly according to age [30]. Overall, the effectiveness of the influenza vaccine among working-age people (18–64 years old) was 58%. Although hospitalization due to influenza or pneumonia did not affect the overall mortality rate, it was found that vaccination for influenza decreased the hospitalization rate among people with diabetes of working age. In addition, vaccination for influenza among older adults (over 65 years old) has been demonstrated to reduce mortality rates from all causes, hospitalization rates from all causes, and hospitalization rates from influenza or pneumonia [30].

The findings mentioned above prove that the influenza vaccine is important, regardless of age and comorbid diseases. Thus, efforts to increase the influenza VCR are required. VCRs vary from country to country, and the factors affecting the rate within each country are different [31]. Therefore, in this study, we sought to identify the factors associated with the influenza VCR in South Korea.

According to the most recent data, the influenza VCR among people with diabetes in South Korea was 60.6%. In a recent study, the goal was to increase the influenza VCR to 90% among people over 65, and 60% among high-risk groups aged 18–64 in the United States [32]. In comparison with these numbers, the VCR in South Korea has met the target rate. The high VCR can be attributed to the South Korean medical system. In South Korea, the National Health Insurance Service is mandatory for everyone. Under this program, people receive deductions for a significant portion of medical costs. They also receive benefits when utilizing health management services. The cost of influenza vaccination varies slightly depending on the type of vaccine and hospital, but does not exceed \$50. As per the national policy, people aged above 65 receive free immunization.

Although the VCR across risk groups and countries continues to increase, few countries are close to achieving the VCR target set by the WHO [28]. In the univariate analysis, many variables, such as gender, educational level, smoking, exercise, drinking, marital status, private health insurance, activity limit, economic activity, age, and EQ-5D score were found to be associated with the VCR. However, the multivariate analysis revealed that only age and economic activity were associated with the VCR. This

study demonstrates that there are only two individual patient factors that are associated with VCRs. Ultimately, national health programs are necessary to increase the VCR among patients with diabetes.

A study of 10 countries in Africa, Asia-Pacific, Eastern Europe, Latin America, and the Middle East demonstrated that the influenza VCR is not affected by patient factors [33]. This is similar to our findings and suggests that national programs are necessary to increase the influenza VCR [33]. Indeed, the UK has achieved its target VCR, and this is the result of active national support and health programs [34].

Although the rates were calculated in different years, a study conducted in five European countries demonstrated that the influenza VCRs among patients with chronic diseases, such as diabetes, were as follows: 59.4% in the UK, 29.8% in Germany, 36.7% in Italy, 34.4% in France, and 37.1% in Spain [35].

In a large-scale study in European countries conducted after the previously mentioned study, an increase in VCRs was observed [34]. However, they still did not reach the rate recommended by the WHO, indicating that management at the national level is necessary [34].

Contradictory to our results, some studies have suggested that several factors affect VCRs. A study in Singapore revealed that high income and high educational levels were associated with high VCR [36]. A study in Spain demonstrated that the following factors affect the influenza VCR: age, urban residence, income, marriage, health awareness, and caregivers [37]. A study of older adults in Brazil revealed that the factors that increase the influenza VCR include old age, being male, high income, high educational level, non-smoking, and solicitation [38]. In Canada, research demonstrated that higher education, higher income, smoking, increased levels of drinking, poor health perception, exercise, and city dwelling increased the influenza VCR [39]. A nationwide study in Spain revealed that old age, previous vaccination, chronic disease, and being female increased the influenza VCR among the vulnerable population [40]. In France, it was demonstrated that VCRs were higher in families with infants, higher educational levels, professional occupations, and previous influenza vaccination [40].

Influenza, which can be prevented through vaccination, causes significant economic losses. In the United States, the total annual cost related to influenza is €10,000–17,000 million [34]. French research estimates that the total cost related to influenza is over €1,796 million per year [34]. These economic losses highlight the importance of increasing the influenza VCR.

Based on the most recent data, the present study analyzed the factors associated with the influenza VCR among people with diabetes in South Korea. However, it does have limitations. First, owing to the use of cross-sectional data, causality cannot be established. Second, not all factors that could be associated with vaccination history were considered.

5. Conclusions

This study demonstrated that the influenza VCR is low in younger and employed people, possibly owing to time constraints. Overall, the influenza VCR is rarely associated with personal factors in people with

diabetes. The results suggest that owing to the governmental healthcare system's major impact on the VCR, and based on the fact that only two personal factors were associated with the influenza VCR, government intervention is necessary to increase the influenza VCR. Thus, it would be helpful to develop a national program that connects companies with public health centers with the joint goal of improving VCRs.
