Abstract

Background

Tick-Borne Encephalitis (TBE) is a viral infection of the Central Nervous System (CNS) caused by Tick-Borne Encephalitis Virus (TBEV). It might take several clinical courses such as: meningitis, meningoencephalitis or meningoencephalomyelitis. The aim this study was to compare the YKL-40 concentration in cerebrospinal fluid (CSF) of patients with different clinical presentations of TBE and patients with excluded meningitis (control group).

Methods

The concentration of YKL-40 in CSF was determined using Fujirebio tests (Ghent, Belgium) in 32 patients with TBE: group I—patients with meningoencephalitis (n = 16); group II—patients with meningitis (n = 16). The control group (CG) consisted of 17 patients in whom inflammatory process in central nervous system was excluded.

Results

The concentration of YKL-40 was significantly higher in encephalitis group than in CG after 7 days from the last dose of treatment. The concentration in patients with neuroinflammation had significantly different concentration of YKL-40 compared to patients with no neuroinflammation control groups. ROC curve analysis indicates that: CSF YKL-40 concentration at cut off 783.87 differentiated TBE patients from CG with 100% specificity and 70% sensitivity and CSF YKL-40 concentration at cut off 980.11 differentiated meningitis from meningoencephalitis with 87.5% specificity and 62.5% sensitivity.

Conclusions

YKL-40 takes part in TBE pathogenesis, its concentration is the highest at the early stage of Central Nervous System involvement and decreases in the convalescent period. As YKL-40 is significantly higher in meningitis than in meningoencephalitis, it might be used as biomarker in differentiation of these clinical forms of TBE.

Introduction

Tick-Borne Encephalitis (TBE) is a viral infection of the Central Nervous System (CNS) caused by Tick-Borne Encephalitis Virus (TBEV) transmitted by *Ixodide* tick bite that might lead to severe sequelae [1, 2]. The annual incidence of TBE in Poland is 200–300 with 90% of them are from two regions of the two northeastern provinces of the country [3]. In years 2000–2015, 3662 cases were reported in Poland at

country level where 45% of them were from the Podlaskie province (the place where this study is conducted) [4].

The clinical features of TBE elapse from asymptomatic to cognitive and neurologic impairments. It could appear as meningitis, meningoencephalitis, and meningoencephalomyelitis [5]. According to various reports 20–58% of patients may develop sequelae after TBE (mild, moderate or severe) while others completely recover from their illness without indications of sequelae [6, 7].

It has been proven that some neurodegenerative diseases such as Alzheimer's Disease (AD) might be induced by infectious diseases [8, 9]. In two previous studies conducted in the same institution we have observed that Neuron Specific Enolase (NSE) and tau protein were increased in cerebrospinal fluid (CSF) [10, 11] which suggested that TBE may lead to neurodegeneration.

Therefore we wanted to assess whether other markers of neurodegeneration also take part in the pathogenesis of TBE. We decided to choose YKL-40 (chitinase-3 like-1 [CHI3L1]) a member of the family 18 glycosyl hydrolases, secreted by activated neutrophils and macrophages. In the central nervous system (CNS), YKL-40 is mostly expressed by microglia, especially when responding to acute and chronic inflammation [12, 13, 14].

The aim of this study was to assess the YKL-40 concentration in CSF of patients with different encephalitis and meningitis associated with TBE.

This study has the following specific objectives:

- Evaluation of YKL-40 concentration in patients with TBE in cerebrospinal fluid before and after treatment
- Comparison of YKL-40 concentration in patients with TBE and patients with excluded meningitis
- Comparison of YKL-40 concentration in patients with meningoencephalitis and meningitis
- Comparison of YKL-40 concentration in patients with and without sequelae

Material And Methods

The concentration of YKL-40 in CSF was measured among patients treated for TBE in the department of Infectious Diseases and Neuroinfections of Medical University of Białystok.

All patients treated during the time of the study were analyzed and divided into two groups based on their clinical diagnosis:

- Group I: patients with meningoencephalitis (n = 16; 7 women, 9 men, mean age 54.5 ± 8.93 years). Meningoencephalitis was diagnosed when the inflammatory parameters in CSF, altered consciousness and focal neurological symptoms were present.

- Group II: Patients with meningitis (n = 16: 6 women and 10 men, mean age 56.7 ± 10.46 years). Meningitis was diagnosed on the basis of inflammatory parameters in CSF with no focal neurological symptoms.

During this study, no patient was hospitalized due to meningoencephalomyelitis.

None of the participants were vaccinated for TBE. TBE was diagnosed based on the clinical picture, presence of inflammatory parameters in the CSF, and specific antibodies present in serum and CSF. TBE antibody titer was measured with Enzygnost Anti-TBE/FSME Virus (IgG, IgM) Siemens test. A case of TBE was diagnosed according to EAN rules [15]. No patient had a history of any neurodegenerative disorder that could have effect to the result of the study. Patients were treated with 0.25 g/kg 15% Mannitol per dose 2–4 times a day and, if needed, NSAIDs (ketoprofenum) was also administered. The treatment lasted for 4–7 days and the effect of treatment on the study was considered by collecting sample 1 before treatment initiated and sample 2 taken after seven days after drug withdrawal.

The control group (CG) consisted of 17 patients (6 women, 11 men, mean age 50.1 ± 10.39 years). These group of patients were admitted to the hospital with a complaint of headache with a ruled out CSF inflammatory process (mean cytosis – $3,4 \pm 1.804$ cells/ μ L; protein concentration – $36,67 \pm 10.66$ mg/dL). They also had no history of neurodegenerative disorders.

The concentration of YKL-40 (ng/ml) in CSF was determined using Fujirebio test (Ghent, Belgium). YKL-40 concentration in CSF was measured on admission (Sample 1) and 14 days after admission or seven days after drug withdrawal (Sample 2). The ratio of sample 2 against sample 1 (YKL 2/YKL 1) was also calculated to identify the effect of treatment on YKL-40. As a follow up, patients were examined for the presence of sequelae in the outpatients department.

Patients voluntarily agreed to participate in the study and gave their written informed consent.

The study was approved by the Local Bioethics Committee of the Medical University of Bialystok.

The statistical analysis was performed using STATISTICA 10. Groups were compared with Mann-Whitney U test, Wilcoxon-matched pair test and receiver operating characteristic curve (ROC) tests. Correlations were measured by the Spearman rank test.

Results

The main complains reported by TBE patients were headache 30/32 patients, fever 29/32 patients, nausea 12/32 patients, vertigo 8/32 patients, vomits 3/32 patients.

Patients diagnosed with meningitis had no focal neurological symptoms. All patients diagnosed with meningoencephalitis presented with consciousness disturbances. The main neurological symptoms in this group were: ataxia 6/16 patients, tremor 5/16 patients, paresis 4/16 patients, pyramidal symptoms 1/16 patients.

The laboratory parameters of patients are presented in Table 1.

Table 1
The laboratory parameters of patients included to the study

Variable	Encephalitis		Meningitis	
	Mean	SD	Mean	SD
WBC (x 10 ⁹ /per microliter)	8.48	3.5	9.18	3.007
CRP (mg/dl)	5.35	6.125	5.51	8.424
AST (IU/L)	26.93	12.929	24.75	17.613
ALT (IU/L)	46.93	42.433	34.33	28.404
CSF I – cytosis (cells/μL)	137.63	147.872	115.93	83.244
CSF I – polynuclear cells (cells/μL)	69.25	151.195	54.4	60.422
CSF I – protein (mg/dL)	60.19	22.466	73.94	28.707
CSF II – cytosis (cells/μL)	23.71	21.670	44.25	24.981
CSF II – polynuclear cells (cells/μL)	3.0	3.549	3.4	4.623
CSF II – protein (mg/dL)	67.64	54.272	75.09	41.965

8/32 patients developed sequelae – mild cognitive disorders and persistent headache – 4 patients, paresis – 4 patients.

Mean YKL-40 concentration in CSF in sample 1 was significantly higher in both examined groups (Group I and II) than in CG ($p < 0.05$). It was also significantly higher in Group II than in Group I ($p < 0.05$) (Table 2).

Table 2

Concentration of YKL-40 in serum and CSF of patients with TBE in the form of encephalitis (Group I) and meningitis (Group II) before (Sample 1) and after treatment (Sample 2)

	Sample 1 Mean \pm SD YKL-40 (ng/ml)		Sample 2 Mean \pm SD YKL-40 (ng/ml)		p Sample 1 vs Sample 2	
	serum	CSF	serum	CSF	serum	CSF
TBE	102.38 \pm 63.2	1475.37 \pm 913.86	100.73 \pm 84.96	827.68 \pm 529.71	s	< 0.05
Group I	103.22 \pm 80.95	1190.58 \pm 982.51	99.99 \pm 112.09	774.5 \pm 632.5	ns	ns
Group II	101.54 \pm 41.24	1760.149 \pm 766.545	101.48 \pm 48.5	880.87 \pm 416.91	ns	< 0.05
CG	91.39 \pm 62.43	311.53 \pm 240.59				
p Group I vs. Group II	ns	< 0.05	ns	ns		
p Group I vs. CG	ns	< 0.05				
P Group II vs. CG	ns	< 0.05				

ROC curve analysis indicates that YKL-40 protein concentration in CSF differentiates TBE patients from CG. At the cut-off at 783.87 ng/ml specificity is 100% and sensitivity 75%. AUC = 0.915, $p < 0.05$ (Fig. 1).

ROC curve analysis indicates that YKL-40 protein concentration in CSF differentiates meningitis and meningoencephalitis. At the cut-off 980.11 ng/ml specificity is 87.5% and sensitivity 62.5% AUC = 0.711, $p < 0.05$ (Fig. 2).

Serum concentration of YKL-40 did not differ in Sample 1 and 2 neither in meningitis nor in meningoencephalitis group.

CSF concentration of YKL-40 measured in sample 2 was significantly lower ($p < 0.05$) than in sample 1 in meningitis group while in meningoencephalitis group the result was nonsignificant.

The serum YKL-40 ratio in Group I was 1.23 ± 0.62 ng/ml and in Group II 1.11 ± 0.4 ng/ml. The result was non-significant.

The CSF YKL-40 ratio in Group I was significantly lower than in Group II (2.1 ± 2.13 vs 2.2 ± 0.79 ng/ml $p < 0.05$).

Comparison of sequelae group and other TBE patients did not show any statistically significant difference as far as YKL-40 concentrations in serum and CSF are concerned.

In the whole TBE group correlation between YKL-40 concentration and CSF protein concentration was observed (Sample 1: $R = 0.39$ $p < 0.05$, Sample 2 – $R = 0.59$ $p < 0.05$). Also YKL-40 serum concentration in Sample I correlated with WBC count at admission ($R = 0.41$ $p < 0.05$). YKL-40 CSF concentration correlated with neutrophils count in Sample 1 (Sample 1: $R = 0.57$ $p < 0.05$) and lymphocyte count in both samples (Sample 1: $R = 0.62$, Sample 2: $R = 0.46$ $p < 0.05$).

Discussion

In our previous studies we reported that TBE may lead to neurodegeneration. First of all we observed that patients with a history of TBE in MRI present with cerebral atrophic lesions that cannot be explained by age [16]. Also we found out that several neurodegeneration markers are increased in TBE patients. Neuron-specific enolase (NSE) concentration in CSF of patients with meningoencephalitis was significantly higher than in controls and in patients with meningitis. What is more NSE concentration in the CSF was higher in sample 2 than in sample 1 which implied that neurodegenerative processes were ongoing even after clinical recovery [11].

The same phenomenon was stated in our another study concerning Tau protein in the CSF of TBE patients. Additionally we observed that Tau protein concentration might be a predictor of sequelae development in the course of TBE [10].

In the current study we evaluated the usefulness of another well-known neurodegeneration biomarker – YKL-40 protein. Contrary to NSE and Tau protein, YKL-40 concentration was the highest at the beginning of the disease and decreased in the recovery phase. What is even more interesting it was significantly higher in the meningitis group, usually associated with mild course of the disease.

YKL-40 seems not very useful for prognosis of sequelae development as both serum and CSF concentrations were comparable in patients who recovered completely and those who presented with persisting symptoms.

This is in disagreement to most reports that associate YKL-40 concentration increase with unfavorable course of many diseases.

According to the literature YKL-40 proved to be a promising biomarker in various diseases.

High concentrations of YKL-40 in serum are correlated to morbidity of such different diseases as community-acquired pneumonia, active rheumatoid arthritis, and ongoing hepatic fibrosis, as well as to mortality of recurrent breast cancer and colorectal cancer [12, 17, 18, 19, 20, 21]. It has been proven that this protein takes part in Alzheimer disease development and can be used in prediction of dementia development risk among cognitively normal subjects [13] and for prognosis in NMDR encephalitis [14].

Østergaard et al. reported that increased concentrations of YKL-40 were found in patients with purulent meningitis [12]. The authors did not find any clear correlations with severe outcome or mortality. However they observed that YKL-40 CSF concentration correlated with neutrophils and lymphocyte count. This is in accordance with our study. In TBE neutrophils number in CSF is usually elevated at the early stage of CNS infection while at the later stage of the disease lymphocytes predominate.

Neutrophils migrate into CSF of patients with TBE independently of the lymphocyte influx and BBB disruption. Of chemokines attracting neutrophils at least IL-8 and CXCL1 create chemotactic gradients towards CSF and may be responsible for neutrophil recruitment, and CXCL1 concentration correlates with CSF neutrophil count and with encephalitic presentation [22]. This would partially explain the increased concentration of YKL-40 in CSF Sample 1. However as the neutrophil count was higher in meningoencephalitis group, some other mechanisms of YKL-40 release to CSF have to be involved. Also the connection between lymphocytes and YKL-40 is unknown.

The results of our study should be interpreted with special care. The examined group was relatively small and no patients with the most severe form of TBE – meningoencephalomyelitis were hospitalized at the time of the study. Also limited funding of the study did not allow us to correlate YKL-40 concentrations with other markers of neurodegeneration.

Conclusions

YKL-40 takes part in TBE pathogenesis, its concentration is the highest at the early stage of Central Nervous System involvement and decreases in the convalescent period.

As YKL-40 is significantly higher in meningitis than in meningoencephalitis, it might be used as biomarker in differentiation of these clinical forms of TBE.

Declarations

Ethical Approval and Consent to participate: Patients voluntarily agreed to participate in the study and gave their written informed consent. The study was approved by Local Ethical Committee.

Consent for publication: All authors declare their consent for publication.

Availability of supporting data: Yes

Competing interests: Authors declare no conflict of interests.
