# Abstract

**Background** To explore the predictive value of quick Sequential Organ Failure Assessment (qSOFA) score for death in emergency department (ED) resuscitation room among adult trauma patients.

**Methods** During the period November 1, 2016 to November 30, 2019, we retrospectively collected data of adult trauma patients triaged to ED resuscitation room of the First Affiliated Hospital of Soochow University. Take death occurred in ED resuscitation room as the study endpoint. Univariate and multivariate analyses were performed to explore the association between qSOFA score and death. Receiver operating characteristic (ROC) curve analysis was also performed for death.

**Results** A total of 1739 trauma victims were admitted, including 1695 survivors and 44 non-survivors. The death proportion raised with qSOFA score: 0.60% for qSOFA=0, 3.28% for qSOFA=1, 12.06% for qSOFA=2, and 15.38% for qSOFA=3,  $p < 0.001$ . Subgroup of qSOFA = 0 was used as a reference. In univariate analysis, crude OR for death with qSOFA = 1 was 5.65 [95% CI 2.25 to 14.24,  $p < 0.001$ ], qSOFA = 2 was 22.85 [95% CI 8.84 to 59.04,  $p < 0.001$ ], and qSOFA = 3 was 30.30 [95% CI 5.50 to 167.05,  $p < 0.001$ ]. In multivariate analysis, with an adjusted OR (aOR) of 2.87 (95% CI 0.84 to 9.87,  $p = 0.094$ ) for qSOFA=1, aOR 6.80 (95% CI 1.79 to 25.90,  $p = 0.005$ ) for qSOFA=2, and aOR 24.42 (95% CI 3.67 to 162.27,  $p = 0.001$ ) for qSOFA=3. The Area Under the Curve (AUC) for predicting death in ED resuscitation room among trauma patients was 0.78 [95% CI, 0.72–0.85].

**Conclusions** qSOFA score can assess the severity of emergency trauma patients and has good predictive value for death in ED resuscitation room.

## Background

Trauma continues to be an important public health problem worldwide, including in China. With the increase of Chinese economy, severe and mass traumas caused by high-energy factors such as road traffic and high falling have an increasing tendency. Officially reported rate of road traffic injuries, disability and deaths increased significantly with rapid motorization beginning in the late 1980s, road traffic injuries and corresponding deaths take a significant threat on China's population health [1].

The World Health Organization data showed that the incidence of road traffic fatality (18.8/100 000 population) in China was higher than the average for developed and developing countries (9.2 and 18.4 deaths per 100 000, respectively) [2]. Globally, road traffic accidents are the leading cause of death among young people, particularly among young people aged 15–29 years [2].

An appropriate score to predict the mortality risk in trauma cases is necessary. In the last 40 years, a variety of Anatomical Scoring Systems, Physiological Scoring Systems, Combination of Anatomic and Physiological Scoring Systems, represented respectively by Injury Severity Score (ISS), Revised Trauma Score (RTS), Trauma and Injury Severity Scores (TRISS), had been developed to indicate severity of trauma, assess the prognosis and guide the therapeutic strategy among trauma victims [3–5].

Experts and scholars are still innovating to bring up with other scoring systems, such as Mechanism, Glasgow Coma Scale, Age, and Arterial Pressure (MGAP), Glasgow Coma Scale, Age, and Systolic Blood Pressure score (GAP), New Trauma Score (NTS) and Trauma Rating Index in Age, Glasgow Coma Scale, Respiratory rate and Systolic blood pressure score (TRIAGES) [6–10].

The qSOFA score was recently recommended as a simple and quick tool to estimate risk of complications in patients outside the Intensive Care Unit (ICU) with suspected infection [11–13]. The qSOFA score has also been utilized to predict mortality risk in patients without suspected infection [14–18].

The intention of this study was to investigate the correlation between qSOFA score and death in ED resuscitation room among trauma patients. We hypothesized that qSOFA score would be associated with injury severity among trauma patients and could be used as a good predictor for mortality.

## Methods

### Study design, setting

The retrospective study was performed in the First Affiliated Hospital of Soochow University, Suzhou, China. Take death occurred in ED resuscitation room as the study endpoint. We explored the validity of qSOFA score for predicting death in ED resuscitation room among trauma cases.

### Selection of participants and data collection

Adult patients who underwent traumas and triaged to ED resuscitation room between November 1, 2016 and November 30, 2019 were included. Trauma patients triaged to consulting room and without complete information that the study required were excluded.

From the Meehealth emergency information system, we collected demographic data (age, sex), initial vital signs (systolic blood pressure (SBP), respiratory rate (RR), pulse rate, temperature, and oximetry), level of consciousness and Glasgow Coma Scale scores (GCS) at presentation, death time in ED resuscitation room.

The qSOFA score (range, 0–3 points) consists of three elements, assigning one point each to: SBP of 100 mmHg or less, RR of 22/min or greater, and altered mentation [11, 13]. RTS as a tool for evaluation of trauma outcome is calculated by adding the coded values of GCS, SBP and RR [4].

### Statistical analysis

Continuous variables were tested for normality using Shapiro–Wilk test. All of the continuous variables failed to conform to normality were expressed as median (IQR) and compared using Mann-Whitney test. Categorical variables were expressed as frequencies and percentages and compared using Likelihood-ratio Chi squared test. Spearman correlation was used to evaluate relationships of variables. Logistic regression models were performed to calculate the odds ratios (ORs) of variables for death. ROC curve was performed to evaluate the AUC of predictor for death. Statistical analyses and graphics were completed with STATA 15.0. Two-tailed  $P < 0.05$  was considered to be statistically significant.

# Results

Demographic and clinical data are shown in Table 1. During the study period, there were 1739 admissions. There were no significant differences in sex and age between the survivor and non-survivor group ( $P > 0.05$ ). Significant difference was found in the length of stay in ED resuscitation room between two groups ( $P < 0.001$ ). In correlation analysis, qSOFA score was negatively associated with RTS ( $r = -0.38$ ,  $p = 0.001$ ).

**Table 1. Baseline characteristics**

Variables	Survivor 1695 (97.47%)	Non-survivor 44 (2.53%)	P value
<b>Sex</b>			0.532
Female	457 (26.96%)	10 (22.73%)	
Male	1238 (73.04%)	34 (77.27%)	
<b>Age (years)</b>	51 (25)	50 (20)	0.757
<b>RTS</b>	12 (0)	8 (6)	$< 0.001$
<b>qSOFA</b>	0 (1)	1 (1)	$< 0.001$
<b>Hours in the ED</b>	4 (13)	13 (30)	$< 0.001$

Continuous variables were expressed as median (IQR); categorical variables were expressed as n/percentage; P values were calculated by Mann-Whitney test.

Patients were divided into four subgroups according to qSOFA scores at presentation to ED resuscitation room. Of the 1739 study objects, 1006 (57.85%) had a qSOFA score of 0, 579 (33.29%) had a score of 1, 141 (8.11%) had a score of 2, and 13 (0.75%) had a score of 3. An analysis of qSOFA score associated with death proportion is illustrated in Fig 1. The death proportion raised with qSOFA score: 0.60% (6/1006) for qSOFA=0, 3.28% (19/579) for qSOFA=1, 12.06% (17/141) for qSOFA=2, and 15.38% (2/13) for qSOFA=3,  $p < 0.001$ .

**Fig 1. Barchart for the death proportions of qSOFA subgroups**

The death proportions of the four qSOFA subgroups were significantly different (0.60%, 3.28%, 12.06% and 15.38%,  $p < 0.001$ ).

Subgroup of qSOFA = 0 was used as a reference. In univariate analysis (Fig 2), crude OR for death with qSOFA = 1 was 5.65 [95% CI 2.25 to 14.24,  $p < 0.001$ ], qSOFA = 2 was 22.85 [95% CI 8.84 to 59.04,  $p < 0.001$ ], and qSOFA = 3 was 30.30 [95% CI 5.50 to 167.05,  $p < 0.001$ ]. Given the association between elevated qSOFA scores and increased likelihood of death on univariate analyses, we determined if this association would also be present on multivariate analyses. In multivariate analysis (Fig 2), the qSOFA score  $\geq 2$  was significantly associated with death, with an Adjusted OR (aOR) of 2.87 (95% CI 0.84 to 9.87,  $p = 0.094$ ) for qSOFA=1, aOR 6.80 (95% CI 1.79 to 25.90,  $p = 0.005$ ) for qSOFA=2, and aOR 24.42 (95% CI

3.67 to 162.27,  $p = 0.001$ ) for qSOFA $\geq 3$ . qSOFA scores of 2 or more were significantly associated with death after adjustment for other factors (gender, age, RTS).

## Fig 2. Forestplot of crude ORs and adjusted ORs of qSOFA

OR, odds ratio; RTS, Revised Trauma Score; crude ORs were calculated by univariable logistic regression model; aORs were calculated by multivariable logistic regression of qSOFA, sex, age and RTS.

We used a ROC curve to determine predictive capacity of qSOFA score for death (Fig 3). The AUC for predicting death in ED resuscitation room among trauma patients was 0.78 [95% CI, 0.72-0.85] (moderate predictive ability).

## Fig 3. Receiver operating characteristic curve of qSOFA predicting death

## Discussion

Predicting risk of death in ED resuscitation room among trauma patients is the focus of clinical practice. A prediction tool that is accurate and easy-to-use is expected by clinicians.

qSOFA, as a simple novel prediction score, is used to predict in-hospital mortality in non-ICU patients with suspected infection [11]. Studies have also verified the validity of qSOFA in predicting outcome of ED patients with and without suspected infections [18], as well as patients with burn, cancer, pesticide poisoning, and blunt trauma [14-17].

We performed a single center, retrospective study of adult trauma patients triaged to ED resuscitation room. In the current study, our purpose was to explore the predictive validity of qSOFA for death in ED resuscitation room among trauma patients. This study demonstrates that qSOFA score has good correlation with death, higher qSOFA score means higher risk of death.

RTS has been developed for use in triage and outcome prediction among injury patients [4]. High score of RTS indicates high survival probability [4]; but high score of qSOFA means low survival probability. qSOFA score was negatively correlated with RTS ( $r = -0.38$ ,  $p < 0.001$ ). This result was also confirmed by R.S. Jawa et al. [17], supporting our result. These data further suggest that high qSOFA score is indicative of a risk of an unfavorable prognosis following trauma.

In the present study, patients with a qSOFA score of 0 had a 0.6% incidence rate of death. As the qSOFA score increased from 1 to 3, the rate of death significantly increased from 3.28% to 15.38%. The death proportions were significantly higher in patients with qSOFA of 2 or more. We found that elevated qSOFA scores were directly associated with increased death proportion in Likelihood-ratio Chi squared test. This tendency was in concordance with those reported by Singer AJ et al. [18] and R.S. Jawa et al. [17]. In the research by Singer AJ et al., qSOFA score were associated with mortality (0 [0.6%], 1 [2.8%], 2 [12.8%], and 3 [25.0%]). While in the research by R.S. Jawa et al., qSOFA scores were associated with in-hospital mortality (1.7% with qSOFA equals to 0; 8.7% with qSOFA equals to 1; 22.4% with qSOFA equals to 2;

23.1% with qSOFA equals to 3;  $p < 0.001$ ). SilvioA et al. [15] revealed that for patients with qSOFA score  $\geq 2$  vs qSOFA score  $\geq 2$ , the hospital mortality rate was 7.36% vs 35.7% (28.3%; 95% CI, 13%-47.7%,  $p < 0.001$ ). But an interesting result was reported by A. Prasad, et al. [14], the highest mortality rate was in the group of qSOFA score = 2 (12.2%), with none in the group of score = 3, which is inconsistent with our finding, but this result was not discussed by authors.

As higher qSOFA scores were more correlated with death on univariate analysis, we examined its performance by multivariate analysis. Using the multivariate logistic regression (after adjustment for sex, age, RTS), we found qSOFA scores of 2 and 3 were independently associated with death. We cautiously suggest that clinicians should pay more attention and give more frequent monitoring to trauma patients with qSOFA scores of 2 or more at presentation.

Among patients with suspected infection in non-ICU, the AUC of qSOFA for predicting in-hospital mortality was 0.81 (95% CI, 0.80-0.82) [13]. While in our study, the AUC of qSOFA for predicting death was 0.78 [95% CI, 0.72-0.85]. The two predictive values are close. The performance of the qSOFA in the current study was also similar to that reported by Singer AJ et al. [18]. In which, the AUC for predicting mortality among patients with and without suspected infection were 0.75 (95% CI 0.71 to 0.78) and 0.70 (95% CI 0.65 to 0.74), respectively.

In addition, our objects were confined to trauma patients triaged to ED resuscitation room. Trauma victims triaged to consulting room were excluded, they were usually less severely ill and generally at lower risk of death. And our study endpoint was death occurred in ED resuscitation room. Death after leaving the ED resuscitation room was not covered by this study. These might lead to an underestimation of total death toll, and an over- or underestimation of death proportion, even an over- or underestimation of predictive capacity of qSOFA for death.

Several limitations exist in our study. This was a retrospective study from a single center, which is subject to selection bias. The results may not be representative. In the future, large, multi-center retrospective reviews as well as prospective researches may be required to determine whether the qSOFA scores can accurately predict death in ED resuscitation room among trauma patients.

## Conclusions

qSOFA score can assess the severity of emergency trauma patients and has good predictive value for death in ED resuscitation room.

## List Of Abbreviations

qSOFA: quick Sequential Organ Failure Assessment; ED: emergency department; ROC: Receiver operating characteristic; aOR: adjusted OR; AUC: Area Under the Curve; ISS: Injury Severity Score; RTS: Revised Trauma Score; TRISS: Trauma and Injury Severity Scores; MGAP: Mechanism, Glasgow Coma Scale, Age, and Arterial Pressure; GAP: Glasgow Coma Scale, Age, and Systolic Blood Pressure score; NTS: New

Trauma Score; TRIAGES: Trauma Rating Index in Age, Glasgow Coma Scale, Respiratory rate and Systolic blood pressure score; ICU: Intensive Care Unit; SBP: systolic blood pressure; RR: respiratory rate; GCS: Glasgow Coma Scale scores; ORs: odds ratios

## Declarations

**Ethics approval and consent to participate:** This study was approved by the Ethics Committee of the First Affiliated Hospital of Soochow University. The approval number is 2020117. All patient records were anonymized and de-identified and the Ethics Committee waived the need for informed consent before analysis due to the retrospective nature of the data. This study conforms to the principles outlined in the Declaration of Helsinki.

**Consent for publication:** All patient records were anonymized and de-identified and the Ethics Committee waived the need for informed consent for publication due to the retrospective nature of the data.

**Availability of data and materials:** All data generated or analysed during this study are included in this article and its supplementary information files.

**Competing interests:** The authors declare that they have no competing interests.

**Funding:** There are no sources of funding for the research.

**Authors' contributions:** DC conceived the study. DC and PY collected and analysed the data. WJH drafted the manuscript. WJH and DC contributed substantially to its revision. FX supervised the conduct of the study and data collection. All authors read and approved the final manuscript.

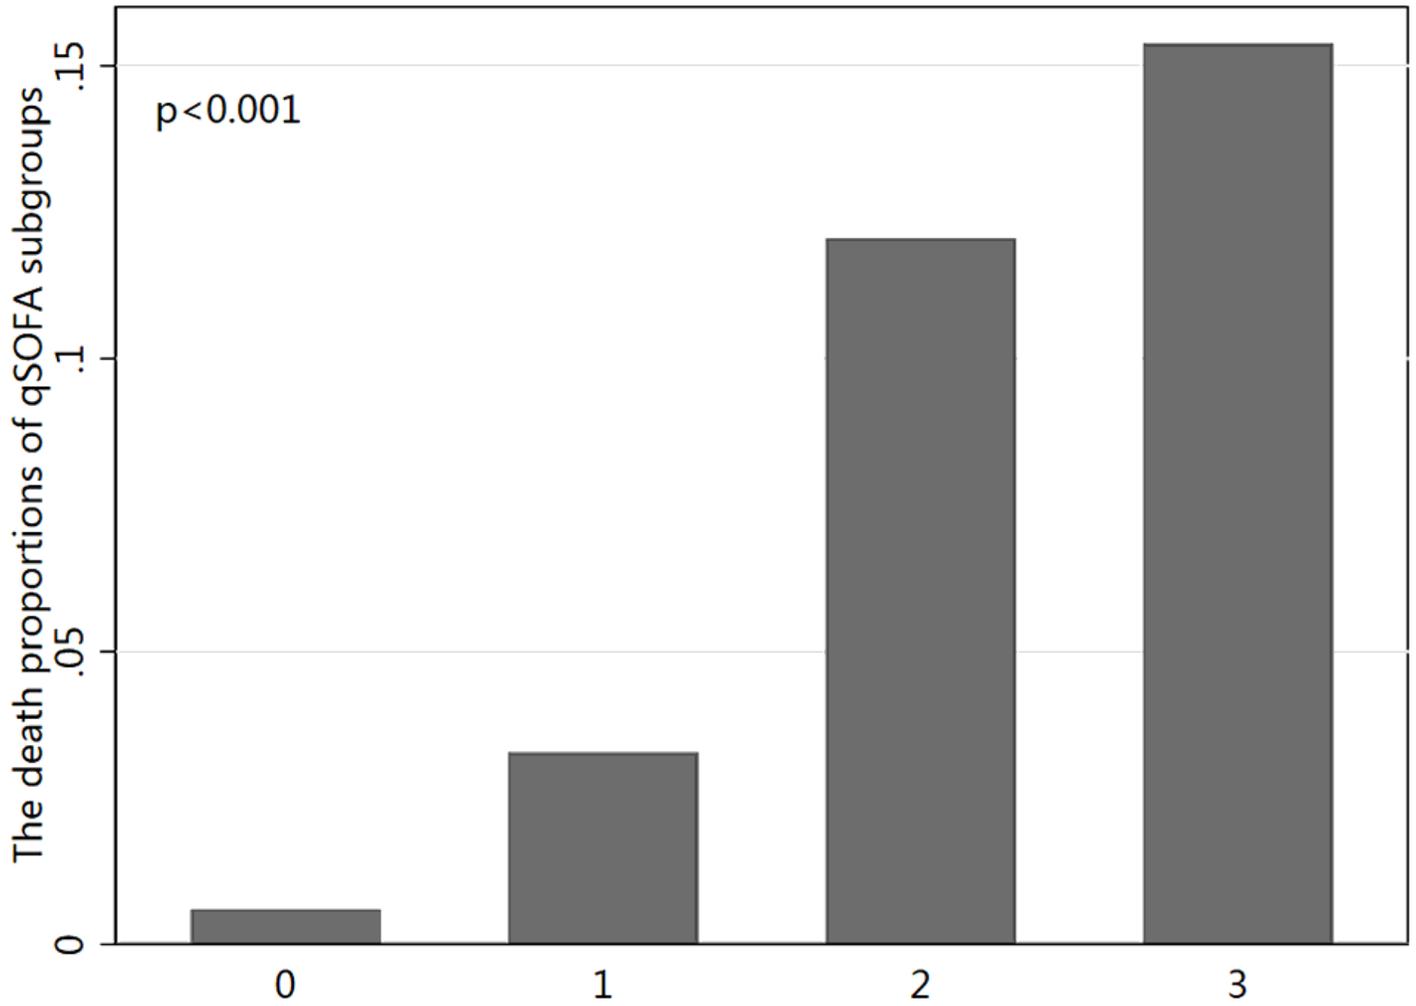

**Acknowledgements:** We would like to acknowledge the First Affiliated Hospital of Soochow University for providing database that supported this research.
