Fractional statistics is one of the most intriguing features of topological phases in 2D. In particular, the so-called non-Abelian statistics plays a crucial role towards realizing universal topological quantum computation. Recently, the study of topological phases has been extended to 3D and it has been proposed that loop-like extensive objects can also carry fractional statistics. In this work, we systematically study the so-called three-loop braiding statistics for 3D interacting fermion systems. Most surprisingly, we discovered new types of non-Abelian three-loop braiding statistics that can only be realized in fermionic systems (or equivalently bosonic systems with emergent fermionic particles). The simplest example of such non-Abelian braiding statistics can be realized in interacting fermionic systems with a gauge group $\mathbb{Z}_2 \times \mathbb{Z}_8$ or $\mathbb{Z}_4 \times \mathbb{Z}_4$, and the physical origin of non-Abelian statistics can be viewed as attaching an open Majorana chain onto a pair of linked loops, which will be naturally reduced to the well known Ising non-Abelian anyons via the standard dimension reduction scheme. Moreover, due to the correspondence between gauge theories with fermionic particles and classifying fermionic symmetry-protected topological (FSPT) phases with unitary symmetries, our study also gives rise to an alternative way to classify FSPT phases. We further compare the classification results for FSPT phases with arbitrary Abelian unitary total symmetry G^f and find systematical agreement with previous studies using other methods. We believe that the proposed framework of understanding three-loop braiding statistics (including both Abelian and non-Abelian cases) in interacting fermion systems applies for generic fermionic topological phases in 3D.

I. INTRODUCTION

Topological phases of quantum matter are new kind of quantum phases beyond Landau's paradigm. Since the discovery of fractional quantum Hall effect (FQHE), fractionalized statistics of point-like excitations in topological phases has been intensively studied in 2D strongly correlated electron systems. In the past decade, the theoretical prediction and experimental discovery of topological insulator and topological superconductor in 3D systems have further extended our knowledge of topological phases into higher dimensions. As a unique feature, the excitations of 3D topological phases not only contain point-like excitations, but also contain loop-like excitations. Therefore, the fundamental braiding process is not only limited to particle-particle braiding, but is also extended to particle-loop braiding and loop-loop braiding. It is well known that due to topological reasons, point-like excitations in 3D can only be bosons or fermions. In addition, particle-loop braiding can be understood in terms of Aharonov-Bohm effect and loop-loop braiding is equivalent to particle-loop braiding (one can always shrink one of the loops into a point-like excitation). As a result, for long time people thought there was no interesting fractional statistics in 3D beyond the Aharonov-Bohm effect. Surprisingly, a recent breakthrough pointed out that loop-like excitations can indeed carry interesting fractional statistics via the so-called three-loop braiding process¹⁻³: braiding a loop α around another loop β , while both are linked to a third loop γ , as shown in Fig. 1. Apparently, such kind of braiding process can not be reduced to the particle-loop braiding due to the linking with a third loop. So far, it has been believed that

the three-loop braiding process is the most elementary loop braiding process in 3D.

Another natural question would be: Whether we can use three-loop braiding process to characterize and classify all possible topological phases for interacting fermion systems in 3D? Recent studies on the classification of topological phases for interacting bosonic and fermionic systems in 3D suggests a positive answer to the above question. Basically, it has been conjectured that all topological phases in 3D can be realized by “gauging” certain underlying symmetry-protected topological (SPT) phases^{4,5}. For bosonic systems, the “gauged” SPT states are known as Dijkgraaf-Witten gauge theory, and it has been shown (at least for Abelian gauge groups) that three-loop braiding process of their corresponding flux lines can uniquely characterize and exhaust all Dijkgraaf-Witten gauge theories⁶. For fermionic systems, some particular examples with Abelian three-loop braiding process are also studied recently⁷. However, it is still unclear how to understand general cases.

In this work, we attempt to systematically understand the three-loop braiding statistics for gauged interacting fermionic SPT (FSPT) systems with general Abelian unitary symmetries. In particular, we discover new types of non-Abelian three-loop braiding statistics that can be only realized in the presence of fermionic particles (accordingly beyond Dijkgraaf-Witten theories). The simplest symmetry group supporting such kind of non-Abelian three-loop braiding process is $\mathbb{Z}_2 \times \mathbb{Z}_8$ or $\mathbb{Z}_4 \times \mathbb{Z}_4$. (More precisely, the corresponding total groups are $G^f = \mathbb{Z}_2^f \times \mathbb{Z}_2 \times \mathbb{Z}_8$ or $\mathbb{Z}_2^f \times \mathbb{Z}_4 \times \mathbb{Z}_4$ if we include the total fermion parity symmetry $\mathbb{Z}_2^f$.) A simple physical picture describing the corresponding non-Abelian statis-

FIG. 1. The so-called three-loop braiding process, that is, braiding one loop α around another loop β , while both of them are linked to a third loop γ

FIG. 2. Attaching an open Majorana chain onto a pair of linked loops realizes the so-called Ising non-Abelian three-loop braiding process.

tics can be viewed as attaching an open Kitaev's Majorana chain onto a pair of linked flux lines ($\mathbb{Z}_2$ and $\mathbb{Z}_8$ unit flux lines for the former case and two different $\mathbb{Z}_4$ unit flux lines for the latter case).

In 1D, it has been shown that a Majorana chain will carry two protected Majorana zero modes on its open ends⁸. In 2D, it is also well known the vortex(anti-vortex) of a p+ip topological superconductor can carry a single topological Majorana zero mode. Thus, it is very natural to ask if flux lines in 3D can also carry topological Majorana zero mode or not. Surprisingly, we find that flux lines carrying topological Majorana zero modes must be linked to each other, as shown in Fig. 2. In contrast, if the loops are unlinked, they can never carry Majorana zero modes, this is because one can always smoothly shrink the flux loops into a point like excitation with a single Majorana zero mode on it. However, as a point like object in 3D can only be boson or fermion, and it is impossible to be an anyon with Ising non-Abelian statistics.

The non-Abelian nature of the new type three-loop braiding process we discovered can be understood as the two-fold degeneracy carried by a pair of linked flux lines, and the braiding statistics between two loops that linked with a third loop should be characterized by a unitary 2 by 2 matrix instead of a simple $U(1)$ phase factor. An alternative way to understand the non-Abelian nature of the three-loop braiding statistics is to use the standard dimension reduction method to deform the 3D lattice model into a 2D lattice model⁹, i.e., by shrinking the z-direction to single lattice spacing such that the

flux line along the z-direction can be regarded as a 2D particle which is exactly the Ising non-Abelian anyon¹⁰ with quantum dimension $\sqrt{2}$. Finally, by explicitly working out all the algebraic constraints of three-loop braiding process for fermionic systems(or equivalently, bosonic systems with emergent fermionic particles), not only we uncover new types of Ising non-Abelian three-loop braiding, but we also derive a completely classification of 3D FSPT phases with Abelian unitary symmetry.

II. OVERVIEW

A. Classification of SPT phases in 3D interacting fermion systems with unitary symmetries

A gapped quantum many-body system is said to be in an SPT phase when the ground state is short-range entangled and does not break any global symmetries. That is, the ground state can be connected to a trivial product state via finite depth local unitary (LU) transformations when the symmetries are broken¹¹. Two states belong to the same SPT phase if they can be connected by finite depth symmetric local unitary (SLU) transformations without closing the energy gap. In low dimensions (up to 3D), the group cohomology theory¹²⁻¹⁴ gives rise to a complete classification of bosonic symmetry-protected topological (BSPT) phases for arbitrary finite unitary symmetry groups. In this classification, BSPT phases have a one-to-one correspondence to the elements in the cohomology group $H^{d+1}(G, U(1))$, where G is the symmetry group and d is the spatial dimension of the system. The group multiplication law in $H^{d+1}(G, U(1))$ corresponds to how the BSPT phases compose under stacking operation. The classification can be generalized to fermionic symmetry-protected topological (FSPT) phases by more advanced constructions¹⁵⁻²⁴. One of these attempts is the so-called (general) group super-cohomology theory, including the incomplete special version proposed in Ref. 15 and the complete scheme that is recently proposed in Refs. 22 and 23.

On the other hand, by gauging the global symmetries in the group G_f of FSPT phases, the gauged system will contain two types of topological excitations: charge excitations which are point-like, and vortex excitations which are point-like in 2D and loop-like in 3D. These excitations obey nontrivial braiding statistics. That is, they are *anyons*¹⁰. Topological invariants that distinguish the original FSPT phases can be defined through the braiding statistics of the charge and vortex excitations. A one-to-one mapping between the classification inferred from braiding statistics and the group super-cohomology classification has been studied explicitly in 2D for general finite Abelian unitary groups²⁵. For 3D FSPT phases, braiding statistics has been studied in Ref. 7 in the case that the loops are Abelian. This paper aims to generalize the study of 3D FSPT phases to the case that there exist non-Abelian loop-like excitations. It is expected that the

same classification as Ref. 23 can be obtained from loop braiding statistics and the associated topological invariants. Indeed, we will show that the two classifications agree for finite Abelian unitary symmetry groups.

Here we briefly summarize the main results of Refs. 22 and 23. We will not consider anti-unitary symmetries such as time reversal, as the braiding statistics method is only applicable to unitary symmetries so far. The (general) group super-cohomology theory is a *layer* construction of fixed-point wave functions of FSPT states. For 3D systems with unitary symmetries, it contains three layers: (1) a BSPT layer described by a $U(1)$ -valued 4-cochain $\nu_4 \in C^4(G_b, U(1))$; (2) a complex fermion layer described by a $\mathbb{Z}_2$ -valued 3-cochain $n_3 \in C^3(G_b, \mathbb{Z}_2)$; (3) A Kitaev-chain layer described by a $\mathbb{Z}_2$ -valued 2-cochain $n_2 \in C^2(G_b, \mathbb{Z}_2)$. In our notation, the total symmetry group G_f is a central extension of the group G_b by

the fermion parity group $\mathbb{Z}_2^f$, through the short exact sequence

$$1 \rightarrow \mathbb{Z}_2^f \rightarrow G_f \rightarrow G_b \rightarrow 1 \quad (1)$$

where inequivalent classes of central extensions are classified by inequivalent 2-cocycles $\omega_2 \in H^2(G_b, \mathbb{Z}_2)$. However, not every choice of (ν_4, n_3, n_2) corresponds to a valid construction of FSPT phase. A valid construction should be both *obstruction-free* and *trivialization-free*.

The (general) group super-cohomology theory is mathematically very solid. However, the computation of obstruction and trivialization is not very handy. The stacking group structure of FSPT phases is not very explicit either. On the other hand, the braiding statistics approach that we will describe gives explicit classification of FSPT phases.

Stacking Group	Cases	Classification
A	If m is odd	$\mathbb{Z}_1$
	If m is even	$\mathbb{Z}_1$
B_i	If m is odd	$\mathbb{Z}_1$
	If m is even	$\mathbb{Z}_{\gcd\{N_0/2, 2N_i\}} \times \mathbb{Z}_{\gcd\{N_0/2, N_i\}}/2$
C_{ij}	If m is odd and $N_i = N_j = 2$	$\mathbb{Z}_2 \times \mathbb{Z}_2$
	If m is odd and $N_i = 2, N_j = 4$	$\mathbb{Z}_4 \times \mathbb{Z}_2$
	If m is odd and $N_i = 2, N_j \geq 8$	$\mathbb{Z}_8 \times \mathbb{Z}_2$
	If m is odd and $4 \leq N_i \leq N_j$	$\mathbb{Z}_{\gcd\{2N_i, N_j\}} \times \mathbb{Z}_{\gcd\{2N_j, N_i\}} \times \mathbb{Z}_2$
	If m is even	$\mathbb{Z}_{\gcd\{2N_i, N_j\}} \times \mathbb{Z}_{\gcd\{2N_j, N_i\}} \times \mathbb{Z}_{\gcd\{N_0/2, N_{ij}\}} \times \mathbb{Z}_{N_{0ij}/2}$
D_{ijk}	If m is odd and $N_i = N_j = N_k = 2$	$\mathbb{Z}_2 \times \mathbb{Z}_2$
	If m is odd, $N_i = N_j = 2$ and $N_k \geq 4$	$\mathbb{Z}_4 \times \mathbb{Z}_2$
	If m is odd and otherwise	$\mathbb{Z}_{N_{ijk}} \times \mathbb{Z}_{N_{ijk}} \times \mathbb{Z}_2$
	If m is even	$\mathbb{Z}_{N_{ijk}} \times \mathbb{Z}_{N_{ijk}} \times \mathbb{Z}_{0ijk}$
E_{ijkl}	If m is odd	$\mathbb{Z}_{N_{ijkl}}$
	If m is even	$\mathbb{Z}_{N_{ijkl}}$

Table I. Classification of 3D FSPT phases with finite unitary Abelian symmetry groups (For simplicity, we only consider symmetry groups $\mathbb{Z}_{N_\mu}$ with N_μ being power of 2, and we assume $N_i \leq N_j \leq N_k \leq N_l$ without loss of generality), where $m = N_0/2$ and "gcd" means the greatest common divisor.

B. Main results

The main purpose of this work is to study non-Abelian loop braiding statistics in three-loop braiding processes of gauged FSPT phases, and to obtain a classification of 3D FSPT phases. We focus on finite Abelian groups of unitary symmetries, which can generally be written as

$$G_f = \mathbb{Z}_{N_0}^f \times \prod_{i=1}^K \mathbb{Z}_{N_i} \quad (2)$$

where a detailed description of the symmetry group is given in Sec. III A.

We start by defining a set of 3D topological invariants $\{\Theta_{\mu,\sigma}, \Theta_{\mu\nu,\sigma}, \Theta_{\mu\nu\lambda,\sigma}\}$ through the three-loop braiding processes (Sec. IV). Our definitions are very similar to those for 2D FSPTs given in Ref. 25, which actually can be related by dimension reduction⁶. Next, we find 14 constraints on $\{\Theta_{\mu,\sigma}, \Theta_{\mu\nu,\sigma}, \Theta_{\mu\nu\lambda,\sigma}\}$, listed in Sec. IV B. Out of these constraints, seven follow directly from 2D constraints²⁵, while the other seven are intrinsically 3D. All intrinsically 3D constraints can be traced back to either the 3D Abelian case⁷ or 3D non-Abelian bosonic case⁶. Unfortunately, we are not able to prove all the constraints; those we can prove are discussed in Supple-

mentary Material. Finally, by solving the constraints, we obtain a classification of 3D FSPT phases in Table I. The classification group H_{stack} under the stacking operation has the following general form,

$$H_{stack} = A \times \prod_i B_i \times \prod_{i < j} C_{ij} \times \prod_{i < j < k} D_{ijk} \times \prod_{i < j < k < l} E_{ijkl} \quad (3)$$

where i, j, k, l take values in $1, 2, \dots, K$, and $A, B_i, C_{ij}, D_{ijk}, E_{ijkl}$ are finite Abelian groups. This classification is one of the main results. While it is obtained from a set of partially conjectured constraints, it agrees with all previously known examples. This justifies the validity of the classification.

At the same time, our exploration uncovers several new kinds of non-Abelian loop braiding statistics, in particular the new kind that involves Majorana zero modes (Fig. 2), which we have briefly mentioned in the introduction. In fact, the correspondence between the layer construction in Refs. 22 and 23 and the three-loop braiding statistics data can be extracted. More explicitly, we pick out several special topological invariants, named *statistics-type indicators*, to indicate non-Abelian loop braiding statistics with different origins:

1. $\Theta_{00i,j} = \pi$ indicates that the original FSPT phase carries the Kitaev-chain layer. That is, the type- i and type- j unit vortices carry unpaired Majorana modes when they are linked. Note that $\Theta_{00i,j} = \pi$ occurs only when m is odd.
2. We define two indicators $\Theta_{fi,j} \equiv \frac{N_{0i}}{\gcd(2, N_i)} \Theta_{0i,j}$ and $\Theta_{fij,k} \equiv \Theta_{ij,k} = m \Theta_{0ij,k}$. (The indicator $\Theta_{fi,j}$ was first introduced in Ref. 7.) When either of them does not vanish, the original FSPT phase contains the complex fermion layer. Moreover, when $\Theta_{fij,k} \neq 0$, the complex-fermion layer exhibits non-Abelian three-loop braiding statistics.
3. When $\Theta_{ijk,l} \neq 0$ or $\{\Theta_{fij,k} = 0, \Theta_{0ij,k} \neq 0\}$, it indicates that non-Abelian three-loop statistics originates from the BSPT layer.

By checking the linear dependence among the topological invariants, we can also determine relations between the three layers, i.e., simply stacked or absorbed. Furthermore, invoking the known model construction for 2D FSPT phases²⁵ and by the fact that quantum dimensions are invariant under dimension reduction, we can find the quantum dimensions of loop-like excitations linked to certain base loops. From the quantum dimensions, we further show that the non-Abelian statistics resulting from the Kitaev-chain layer is due to the unpaired Majorana modes attached to linked loops.

III. PRELIMINARIES

In this section, we first discuss the basics of symmetries in fermionic systems and loop braiding statistics in gauged 3D FSPT phase.

A. Symmetries in interacting fermion systems

Fermionic systems have a fundamental symmetry—the conservation of fermion parity: $P_f = (-1)^{N_f}$, where N_f is the total number of fermions. The corresponding symmetry group is denoted as $\mathbb{Z}_2^f = \{1, P_f\}$. In the presence of other global on-site symmetries, the total symmetry group G_f is the central extension of the bosonic symmetry group G_b by the fermion parity $\mathbb{Z}_2^f$, determined by the short exact sequence Eq. (1) or equivalently by the 2-cocycle $\omega_2 \in H^2(G_b, \mathbb{Z}_2)$. In this work, we consider a general Abelian unitary symmetry group of the following form denoted as:

$$G_f = \mathbb{Z}_{N_0}^f \times \prod_{i=1}^K \mathbb{Z}_{N_i}$$

where $N_0 = 2m$ is an even integer. One can show that any finite Abelian symmetry group in fermionic systems can be written in this form, after a proper isomorphic transformation. Throughout the paper, we use the convention that $\mu, \nu, \lambda, \sigma = 0, 1, 2, \dots, K$, and $i, j, k, l = 1, 2, \dots, K$.

The bosonic symmetry group is expressed as

$$G_b = G_f / \mathbb{Z}_2^f = \mathbb{Z}_{N_0/2} \times \prod_{i=1}^K \mathbb{Z}_{N_i} \quad (4)$$

For simplicity, we will mainly consider the case that m and all N_i are powers of 2, i.e.,

$$N_\mu = 2^{n_\mu}, \quad m = 2^{n_0-1} \quad (5)$$

where $n_0 \geq 1$. When $n_0 = 1$ (i.e. $m = 1$), the central extension of G_b is trivial; when $n_0 \geq 2$, the central extension of G_b is nontrivial. This simplification does not exclude any interesting FSPT phases because odd factors of each N_μ can be factored out. Moreover, n_2 and n_3 are always trivial if all N_i 's are odd integers. Accordingly, neglecting the odd factors, we only lose some BSPT phases, whose classification and characterization are well studied¹².

B. Quasiparticle Excitations and Three-Loop Braiding

To study FSPT phases with symmetry group G_f , we will gauge the full symmetry. That is, we introduce a gauge field of gauge group G_f and couple it to the FSPT system through the minimal coupling procedure (see Refs. 4 and 6 for details of the procedure). The resulting gauged system is guaranteed to be gapped through that procedure, which is actually topologically ordered. It contains two types of topological excitations:

(i) Point-like excitations that carry gauge charge. We label them by a vector $q = (q_0, \dots, q_K)$, where q_μ is an integer defined modulo N_μ . We will use q to denote both

the excitation and its gauge charge. This is legitimate because gauge charge uniquely determines charge excitations. Charge excitations are Abelian anyons. Fusing two charge excitations q_1 and q_2 , we obtain a unique charge excitation $q = q_1 + q_2$.

(ii) Loop-like excitations that carry gauge flux. We call them vortices, vortex loops or simply loops, and label them by $\alpha, \beta, \dots$. The gauge flux carried by loop α is denoted by $\phi_\alpha = (\frac{2\pi}{N_0}a_0, \dots, \frac{2\pi}{N_K}a_K)$, where a_μ is an integer defined modulo N_μ . There exist many loops that carry the same gauge flux, which differ from each other by attaching charges. Unlinked loops are Abelian, however they may become non-Abelian when they are linked with other loops. Hence, fusion of vortex loops depend on whether they are linked or not. Nevertheless, regardless Abelian or non-Abelian, gauge flux always adds up. General vortex excitations are not limited to simple loops. For example, they may be knots or even more complicated structure. In this work, we only consider simple loops and links of them. So far, properties of loops are enough to characterize gauged FSPT systems.

We need to consider three types of braiding statistics between the loops and charges¹:

First, charge-charge exchange statistics. A charge is either a boson or fermion, depending on the gauge charge it carries. More explicitly, the exchange statistics of charge q is given by

$$\theta_q = \pi q_0 \quad (6)$$

That is, when q_0 is odd, it is a fermion. Otherwise, it is a boson. Mutual statistics between charges are always trivial.

Second, charge-loop braiding statistics, which is the Aharonov-Bohm phase given by

$$\theta_{q,\alpha} = q \cdot \phi_\alpha \quad (7)$$

where “ $\cdot$ ” is the vector dot product. We single out a special class of vortex loops, those carrying the fermion parity gauge flux $\phi = (\pi, 0, \dots, 0)$. We denote these *fermion-parity loops* as ξ_f . The mutual statistics between charges and fermion-parity loops are simply given by²⁵:

$$\theta_{q,\xi_f} = q \cdot \phi_{\xi_f} = \pi q_0 \quad (8)$$

We notice that the self-exchange statistics of a charge q is equal to Aharonov-Bohm phase θ_{q,ξ_f} , which is required by the very definition of fermion parity symmetry.

Third, loop-loop braiding statistics. It was shown in Ref. 1 that the fundamental braiding process between loops is the so-called three-loop braiding statistics (Fig. 1):

Let α, β, γ be three loop-like excitations. A three-loop braiding is a process that a loop α braids around loop β while both linked to a base loop γ .

On the other hand, if there is no base loop, the two-loop braiding process can always be reduced to charge-loop braiding statistics:¹

$$\theta_{\alpha\beta} = q_\alpha \cdot \phi_\beta + q_\beta \cdot \phi_\alpha \quad (9)$$

Here q_α is the absolute charge carried by loop α , which can be obtained by shrinking the loop to a point. Since charge-loop braiding statistics is universal for all FSPT phases with the same symmetry group G_f , two-loop braiding is not able to distinguish different FSPT phases. In the presence of a base loop γ , the notion of absolute charge is not well defined as shrinking loop α to a point will inevitably touch the base loop. Accordingly, three-loop braiding statistics can go beyond Aharonov-Bohm phases, as already demonstrated in many previous works.^{1,6,7}

While the gauge group G_f is Abelian, three-loop braiding process is not limited to be Abelian. As mentioned above, linked loops can be non-Abelian in general, and three-loop process involves linked loops. Let us consider loops α, β , which are linked to the base loop γ . The base loop γ carries gauge flux $\phi_\gamma = (\frac{2\pi}{N_0}, \dots, \frac{2\pi}{N_K}) \cdot c$, where c is an integer vector. Generally speaking, the fusion space between α and β , denoted as $V_{\alpha\beta,c}$, is multi-dimensional (we use this notation because the fusion and braiding process only depend on the gauge flux of the base loop). More explicitly,

$$V_{\alpha\beta,c} = \bigoplus_{\delta} V_{\alpha\beta,c}^{\delta} \quad (10)$$

where loop δ are the possible fusion channels of α and β . Braiding between α and β is a unitary transformation in the fusion space, which in general is not just a phase, but a matrix, leading to non-Abelian three-loop braiding statistics. Similarly to anyons in 2D, one can define fusion multiplicities $N_{\alpha\beta,c}^{\delta}$, F - and R -matrices to describe the loop fusion and braiding properties.⁶ We give more detailed description in Supplementary Material.

IV. TOPOLOGICAL INVARIANTS

In this section, we define the topological invariants $\{\Theta_{\mu,\sigma}, \Theta_{\mu\nu,\sigma}, \Theta_{\mu\nu\lambda,\sigma}\}$ through the three-loop braiding statistics. Then, we discuss the 14 constraints on the topological invariants.

A. Definitions

Generally speaking, the full set of braiding statistics among particles and loops is very complicated, in particular when the braiding statistics are non-Abelian. Here, we define a subset of the braiding statistics data, which we call *topological invariants*. They are Abelian phase factors associated with certain composite three-loop braiding processes, and thereby are easier to deal with. Yet, this subset still contains enough information to distinguish all different FSPT phases, as we will show later.

We will define three types of topological invariants, denoted by $\Theta_{\mu,\sigma}$, $\Theta_{\mu\nu,\sigma}$ and $\Theta_{\mu\nu\lambda,\sigma}$ respectively. The

definitions are straightforward generalizations of the 2D counterparts given in Ref. 25. To do that, we introduce a notation. Let ξ_μ be a loop that carries the type- μ unit flux, i.e., $\phi_{\xi_\mu} = \frac{2\pi}{N_\mu} e_\mu$, where $e_\mu = (0, \dots, 1, \dots, 0)$ with the μ -th entry being 1 and all other entries being 0. Then, we define $\Theta_{\mu,\sigma}$, $\Theta_{\mu\nu,\sigma}$, and $\Theta_{\mu\nu\lambda,\sigma}$ as follows. These definitions work for all N_μ , not limited to the special values in Eq. (5).

(i) We define

$$\Theta_{\mu,\sigma} = \tilde{N}_\mu \theta_{\xi_\mu, e_\sigma} \quad (11)$$

where

$$\tilde{N}_0 = \begin{cases} 2m, & \text{if } m \text{ is even} \\ m, & \text{if } m \text{ is odd} \end{cases}$$

$$\tilde{N}_i = \begin{cases} N_i, & \text{if } N_i \text{ is even} \\ 2N_i, & \text{if } N_i \text{ is odd} \end{cases}$$

The quantity $\theta_{\xi_\mu, e_\sigma}$ is the topological spin of the loop ξ_μ , when it is linked to another loop ξ_σ . It is defined as¹⁰:

$$e^{i\theta_{\xi_\mu, e_\sigma}} = \frac{1}{d_{\xi_\mu, e_\sigma}} \sum_\delta d_{\delta, e_\sigma} \text{tr}(R_{\xi_\mu \xi_\mu, e_\sigma}^\delta) \quad (12)$$

where $R_{\xi_\mu \xi_\mu, e_\sigma}^\delta$ is the R -matrix between two ξ_μ loops in the δ fusion channel, and all loops are linked to ξ_σ (see Supplementary Material for details).

(ii) We define $\Theta_{\mu\nu,\sigma}$ as the phase associated with braiding ξ_μ around ξ_ν for $N^{\mu\nu}$ times, when both are linked to the base loop ξ_σ . Here, $N^{\mu\nu}$ is the least common multiple of N_μ and N_ν . In terms of formulas, we have the following expression

$$e^{i\Theta_{\mu\nu,\sigma}} I = (B_{\xi_\mu \xi_\nu, e_\sigma})^{N^{\mu\nu}} \quad (13)$$

where $B_{\xi_\mu \xi_\nu, e_\sigma}$ denotes the unitary operator associated with braiding ξ_μ around ξ_ν only once, while both are linked to ξ_σ , and I is the identity operator. The operator $B_{\xi_\mu \xi_\nu, e_\sigma}$ can be expressed in term of R matrices, and F matrices if needed, once we choose a basis for the fusion spaces.

(iii) We define $\Theta_{\mu\nu\lambda,\sigma}$ as follows. Consider three loops $\xi_\mu, \xi_\nu, \xi_\lambda$ all linked to a base loop ξ_σ . Then, $\Theta_{\mu\nu\lambda,\sigma}$ is the phase associated with braiding ξ_μ around ξ_ν first, then around ξ_λ , then around ξ_ν in opposite direction and finally around ξ_λ in opposite direction.

For the topological invariants $\{\Theta_{\mu,\sigma}, \Theta_{\mu\nu,\sigma}, \Theta_{\mu\nu\lambda,\sigma}\}$ to be well-defined, we need to show that (1) The corresponding braiding processes indeed lead to Abelian phases and (2) the Abelian phases only depend on the gauge flux of the loops, i.e. independent of charge attachments. The proofs are the same as those for the 2D topological invariants $\{\Theta_\mu, \Theta_{\mu\nu}, \Theta_{\mu\nu\lambda}\}$, so we do not repeat them here and instead refer the readers to Ref. 25. (The only addition for 3D is that one needs to carry the base loop index σ in every step of the proofs). The reason that the proofs are identical is that the 3D invariants $\{\Theta_{\mu,\sigma}, \Theta_{\mu\nu,\sigma}, \Theta_{\mu\nu\lambda,\sigma}\}$ can be related to the 2D invariants $\{\Theta_\mu, \Theta_{\mu\nu}, \Theta_{\mu\nu\lambda}\}$ by dimension reduction.⁶

B. Constraints

The topological invariants $\{\Theta_{\mu,\sigma}, \Theta_{\mu\nu,\sigma}, \Theta_{\mu\nu\lambda,\sigma}\}$ should satisfy certain constraints. We claim that they satisfy the following 14 constraints, Eqs. (14)-(20) and Eqs. (25)-(31). While we are not able to prove all the constraints, we believe they are rather complete. At least, the solutions to these constraints are all realized in the layer construction of FSPT phases (see Supplementary Material). We divide 14 constraints into two groups.

Group I: Seven constraints that follow from the 2D counterparts:

$$\Theta_{\mu\nu,\sigma} = \Theta_{\nu\nu\mu,\sigma} = m\Theta_{0\mu\nu,\sigma} \quad (14)$$

$$\Theta_{\mu\nu,\sigma} = \Theta_{\nu\mu,\sigma} \quad (15)$$

$$N_{\mu\nu}\Theta_{\mu\nu,\sigma} = \mathcal{F}(N^{\mu\nu})\Theta_{\mu\nu,\sigma} \quad (16)$$

$$\frac{N_i}{2}\Theta_{ii,\sigma} = \frac{N_{0i}}{2}\Theta_{0i,\sigma} + \left[\frac{N_i}{2}\mathcal{F}(m) + m\mathcal{F}\left(\frac{N_i}{2}\right)\right]\Theta_{00i,\sigma} \quad (N_i \text{ is even}) \quad (17)$$

$$\Theta_{ii,\sigma} = \begin{cases} 2\Theta_{i,\sigma} + \mathcal{F}(N_i)\Theta_{iii,\sigma}, & \text{if } N_i \text{ is even} \\ \Theta_{i,\sigma}, & \text{if } N_i \text{ is odd} \end{cases} \quad (18)$$

$$\Theta_{00,\sigma} = \begin{cases} 2\Theta_{0,\sigma}, & \text{if } m \text{ is even} \\ 4\Theta_{0,\sigma} + \Theta_{000,\sigma}, & \text{if } m \text{ is odd} \end{cases} \quad (19)$$

$$\begin{cases} \frac{m}{2}\Theta_{0,\sigma} = 0, & \text{if } m \text{ is even} \\ m\Theta_{0,\sigma} + \frac{m^2-1}{8}\Theta_{000,\sigma} = 0, & \text{if } m \text{ is odd} \end{cases} \quad (20)$$

where $\mathcal{F}(N) = \frac{1}{2}N(N-1)$.

The constraints (14) to (20) are exactly the 2D fermionic constraints in Ref. 25 with a base loop inserted. Since the 3D topological invariants $\{\Theta_{\mu,\sigma}, \Theta_{\mu\nu,\sigma}, \Theta_{\mu\nu\lambda,\sigma}\}$ are related to the 2D ones $\{\Theta_\mu, \Theta_{\mu\nu}, \Theta_{\mu\nu\lambda}\}$ by dimension reduction, the 3D topological invariants satisfy all the 2D constraints.

We briefly explain the meaning of the above constraints. For constraint (14), firstly we notice a fact that N copies of the topological invariant $\Theta_{\mu\nu\lambda,\sigma}$ is equivalent to do the braiding process for N copies the type- μ loop, or type- ν , type- λ loop, expressed as:

$$N\Theta_{\mu\nu\lambda,\sigma} = \Theta_{[N\xi_\mu]\nu\lambda,\sigma} = \Theta_{\mu[N\xi_\nu]\lambda,\sigma} = \Theta_{\mu\nu[N\xi_\lambda],\sigma} \quad (21)$$

where $[N\xi_\mu]$ means N copies the type- μ loop, which can be obtained directly by the definition of $\Theta_{\mu\nu\lambda,\sigma}$. Then by this fact, the expression $m\Theta_{0\mu\nu,\sigma}$ can be rewritten as²⁵:

$$e^{im\Theta_{0\mu\nu,\sigma}} = e^{i\Theta_{[m\xi_0]\mu\nu,\sigma}} = e^{i\Theta_{f\mu\nu,\sigma}} \quad (22)$$

where f is the fermion-parity loop. And constraint (14) illustrates an equivalence $\Theta_{f\mu\nu,\sigma} = \Theta_{\mu\mu\nu,\sigma}$, explicitly proved in the appendix of Ref. 25. Moreover, as the positions of type- μ and type- ν loops are symmetric in $\Theta_{f\mu\nu,\sigma}$, the equality can be extended to $\Theta_{\nu\nu\mu,\sigma}$. The constraint (15) simply points out that the type- μ and type- ν loops are symmetric in a three-loop braiding process. The constraints (16) and (17) are obtained by rearranging the order of certain braiding processes, where the rearrangements give rise to the non-Abelian phase factors $\Theta_{\mu\mu\nu,\sigma}$ and $\Theta_{00i,\sigma}$. For constraints (18) and (19), there are two corollaries relating the type- μ loop and its anti-loop²⁵:

$$\Theta_{\mu\mu,\sigma} + \Theta_{\mu\bar{\mu},\sigma} = \mathcal{F}(N_\mu)\Theta_{\mu\mu\mu,\sigma} \quad (23)$$

$$\Theta_{\mu\bar{\mu},\sigma} = -2N_\mu\theta_{\xi_\mu,e_\sigma} \quad (24)$$

where $\bar{\mu}$ denotes for the anti-loop $\bar{\xi}_\mu$ with gauge flux $\phi_{\bar{\xi}_\mu} = -\phi_{\xi_\mu}$. Combining the two corollaries and inducing the definition of $\Theta_{\mu,\sigma}$ exactly give constraints (18) and (19). And the constraint (20) is obtained by demanding the chiral central charge vanishes for FSPT phases.

Group II: Seven constraints that are intrinsically 3D:

$$\Theta_{\mu\nu\lambda,\sigma} = \text{sgn}(\hat{p})\Theta_{\hat{p}(\mu)\hat{p}(\nu)\hat{p}(\lambda),\hat{p}(\sigma)} \quad (25)$$

$$N_{\mu\nu\lambda\sigma}\Theta_{\mu\nu\lambda,\sigma} = 0 \quad (26)$$

$$N_\sigma\Theta_{\mu\nu,\sigma} = 0 \quad (27)$$

$$N_\sigma\Theta_{\mu,\sigma} = 0 \quad (28)$$

$$\Theta_{\mu,\mu} = 0 \quad (29)$$

$$\frac{N^{\mu\nu\sigma}}{N^{\mu\nu}}\Theta_{\mu\nu,\sigma} + \frac{N^{\mu\nu\sigma}}{N^{\nu\sigma\mu}}\Theta_{\nu\sigma,\mu} + \frac{N^{\mu\nu\sigma}}{N^{\sigma\mu\nu}}\Theta_{\sigma\mu,\nu} = 0 \quad (30)$$

$$\frac{N^{\mu\sigma}}{\tilde{N}_\mu}\Theta_{\mu,\sigma} + \Theta_{\mu\sigma,\mu} = 0 \quad (N^{\mu\sigma} \text{ is even}) \quad (31)$$

where $\text{sgn}(\hat{p}) = (-1)^{N(\hat{p})}$ and $N(\hat{p})$ is the number of permutations for the four indices $\mu, \nu, \lambda, \sigma$.

The constraints (25) to (31) are newly involved 3D constraints (Specially (26) is a 2D constraint $N_{\mu\nu\lambda}\Theta_{\mu\nu\lambda,\sigma} = 0$ combined with a 3D constraint $N_\sigma\Theta_{\mu\nu\lambda,\sigma} = 0$), which can be traced from 3D bosonic non-Abelian case⁶ and 3D fermionic Abelian case⁷. However, we need to prove that these 3D constraints still hold in 3D fermionic non-Abelian case.

Firstly, we argue that the constraints (30)(31) proved in Abelian case still hold in non-Abelian case. The constraint (30) is called the cyclic relation. Imagining that we create $N^{\mu\nu\sigma}$ identical three-loop systems with identical fusion channel and identical total charge. By anyon

charge conservation, after braiding and fusion, the total charge should still be $N^{\mu\nu\sigma}Q_{link}$, where Q_{link} is the total charge for a single three-loop system. Then the next step of the proof is similar to the Abelian case⁷, where the difference is that the "vertical" fusions may have multiple fusion channels (differ only by charges). But we do not need to care about the charges attached on the resultant loop after fusion, as finally the total charge should still be $N^{\mu\nu\sigma}Q_{link}$, by which we fall into the same result as the proof in Ref⁷. And constraint (31) is actually the cyclic relation (30) divided by half on both sides (mod 2π), which then involves fermionic statistics and hence an intrinsic fermionic constraint. It can be argued that it holds in non-Abelian case in a similar manner.

Then we can rigorously prove the constraints (26) to (28). The prerequisite to prove them is to assume a 3D "vertical" fusion rule, which naturally gives the linear properties of the topological invariants, explicitly shown in Supplementary Material.

However, the constraints (25) and (29) are left unproven. For constraint (25), it is a generalization of the 2D constraint $\Theta_{\mu\nu\lambda} = \text{sgn}(\hat{p})\Theta_{\hat{p}(\mu)\hat{p}(\nu)\hat{p}(\lambda)}$, where the 2D version can be easily proved by a Borromean ring configuration⁶. While here we generalize the totally anti-symmetric property for the indices of $\Theta_{\mu\nu\lambda,\sigma}$ to the base loop. And the constraint (29) is simply a conjecture, which means that the topological invariant $\Theta_{\mu,\sigma}$ vanishes if the two linked loops fall into the same type.

V. CLASSIFICATION

We believe the the topological invariants are complete for characterizing FSPT phases with Abelian symmetry group G_f , and the constraints are complete so that all solutions are physical. Both completenesses are justified by an comparison with the general group super-cohomology method in Supplementary Material.

A. Stacking Group of FSPT Phases

We divide the topological invariants into five categories, such that the topological invariants in each category are independent of those in other categories, i.e. the constraints only relate topological invariants inside each category. The five categories are:

- (A) $\Theta_{0,0}, \Theta_{00,0}, \Theta_{000,0}$
- (B) (B1) $\Theta_{0,i}, \Theta_{00,i}, \Theta_{000,i}$
 (B2) $\Theta_{i,0}, \Theta_{0i,0}, \Theta_{ii,0}, \Theta_{00i,0}, \Theta_{0ii,0}, \Theta_{iii,0}$
 (B3) $\Theta_{i,i}, \Theta_{0i,i}, \Theta_{ii,i}, \Theta_{00i,i}, \Theta_{0ii,i}, \Theta_{iii,i}$
- (C) (C1) $\Theta_{ij,0}, \Theta_{0ij,0}, \Theta_{iij,0}, \Theta_{jjj,0}$
 (C2) $\Theta_{ij,i}, \Theta_{0ij,i}, \Theta_{iij,i}, \Theta_{jjj,i}$
 (C3) $\Theta_{ij,j}, \Theta_{0ij,j}, \Theta_{iij,j}, \Theta_{jjj,j}$
 (C4) $\Theta_{i,j}, \Theta_{0i,j}, \Theta_{ii,j}, \Theta_{00i,j}, \Theta_{0ii,j}, \Theta_{iii,j}$
 (C5) $\Theta_{j,i}, \Theta_{0j,i}, \Theta_{jj,i}, \Theta_{00j,i}, \Theta_{0jj,i}, \Theta_{jjj,i}$

FIG. 3. The diagram expression of $\tilde{B}_{\xi_\nu \xi_\mu \xi_\lambda, e_\sigma}^\eta$ in the standard basis.

- (D) (D1) $\Theta_{ij,k}, \Theta_{0ij,k}, \Theta_{ijj,k}, \Theta_{jjj,k}$
 (D2) $\Theta_{jk,i}, \Theta_{0jk,i}, \Theta_{jjk,i}, \Theta_{kkj,i}$
 (D3) $\Theta_{ki,j}, \Theta_{0ki,j}, \Theta_{kki,j}, \Theta_{iik,j}$
 (D4) $\Theta_{ijk,0}, \Theta_{ijk,i}, \Theta_{ijk,j}, \Theta_{ijk,k}$
 (E) $\Theta_{ijk,l}, \Theta_{jkl,i}, \Theta_{kli,j}, \Theta_{lij,k}$

Accordingly the stacking group to classify 3D FSPT phases has the form:

$$H_{stack} = A \times \prod_i B_i \times \prod_{i<j} C_{ij} \times \prod_{i<j<k} D_{ijk} \times \prod_{i<j<k<l} E_{ijkl} \quad (32)$$

where A is the classification group protected by the symmetry group $\mathbb{Z}_{N_0}^f$, B_i is protected by $\mathbb{Z}_{N_0}^f$ and $\mathbb{Z}_{N_i}$, C_{ij} is protected by $\mathbb{Z}_{N_0}^f, \mathbb{Z}_{N_i}, \mathbb{Z}_{N_j}$, D_{ijk} is protected by $\mathbb{Z}_{N_0}^f, \mathbb{Z}_{N_i}, \mathbb{Z}_{N_j}, \mathbb{Z}_{N_k}$, and E_{ijkl} is protected by $\mathbb{Z}_{N_i}, \mathbb{Z}_{N_j}, \mathbb{Z}_{N_k}, \mathbb{Z}_{N_l}$.

B. Statistics-Type Indicators

We claim that there are several indicators for different statistics-types:

- (1) $\Theta_{00i,j} = \pi$ (m is odd) is the indicator of the non-Abelian statistics in the Kitaev-chain layer, which is generated by the loops carrying unpaired Majorana modes, and a loop carrying one Majorana mode is characterized by its quantum dimension $\sqrt{2}$.

- (2) $\Theta_{fi,j} = \frac{N_{0i}}{\gcd(2, N_i)} \Theta_{0i,j} \neq 0$ ($i \neq j$) is the indicator of the complex fermion layer, where "f" stands for the fermion-parity loop ξ_f with gauge flux $\phi_{\xi_f} = (\pi, 0, \dots)$.

- (3) $\Theta_{fij,k} = \Theta_{iij,k} = m\Theta_{0ij,k} \neq 0$ is the indicator of the non-Abelian statistics in the complex fermion layer, which is generated by degeneracies in the complex fermion layer and the relevant loops have integer quantum dimension.

- (4) $\Theta_{ijk,l} \neq 0$ or $\{\Theta_{fij,k} = 0, \Theta_{0ij,k} \neq 0\}$ is the indicator of the non-Abelian statistics in the BSPT layer, which is generated by degeneracies in the BSPT layer and the relevant loops have integer quantum dimension.

We then prove that the first statistics-type indicator $\Theta_{00i,j} = \pi$ (m is odd) uniquely indicates the Kitaev-chain layer. To proceed, we need to obtain an explicit expression of the topological invariant $\Theta_{\mu\nu\lambda,\sigma}$ as the following (The definitions we used below are introduced in Supplementary Material:

FIG. 4. The diagram expression of $B_{\xi_\mu \xi_\nu, e_\sigma}$ in the standard basis.

Consider three loops $\xi_\mu, \xi_\nu, \xi_\lambda$ all linked to a base loop ξ_σ . Mathematically, let the total fusion outcome η of the three loops $\xi_\mu, \xi_\nu, \xi_\lambda$ be fixed, and the standard basis is to let ξ_ν firstly fuse with ξ_μ , then their fusion channel again fuse with ξ_λ . We choose the basis of the first local fusion space $V_{\xi_\nu \xi_\mu, c}$ to be diagonalized under the braiding of ξ_μ around ξ_ν , and the braiding of ξ_μ around ξ_λ is then generally non-diagonalized under this basis, which is expressed as:

$$\tilde{B}_{\xi_\nu \xi_\mu \xi_\lambda, e_\sigma}^\eta = F_{\xi_\nu \xi_\mu \xi_\lambda, e_\sigma}^\eta B_{\xi_\mu \xi_\lambda, e_\sigma} (F_{\xi_\nu \xi_\mu \xi_\lambda, e_\sigma}^\eta)^{-1} : \bigoplus_\delta (V_{\xi_\nu \xi_\mu, c}^\delta \otimes V_{\delta \xi_\lambda, c}^\eta) \rightarrow \bigoplus_\rho (V_{\xi_\nu \xi_\mu, c}^\rho \otimes V_{\rho \xi_\lambda, c}^\eta) \quad (33)$$

where $\tilde{B}_{\xi_\nu \xi_\mu \xi_\lambda, e_\sigma}^\eta$ only braids ξ_μ around ξ_λ , while it depends on ξ_ν , as shown in Fig.3. And $B_{\xi_\mu \xi_\nu, e_\sigma}$ is redefined in the same basis as $\tilde{B}_{\xi_\nu \xi_\mu \xi_\lambda, e_\sigma}^\eta$:

$$B_{\xi_\mu \xi_\nu, e_\sigma} : \bigoplus_\delta (V_{\xi_\nu \xi_\mu, c}^\delta \otimes V_{\delta \xi_\lambda, c}^\eta) \rightarrow \bigoplus_\delta (V_{\xi_\nu \xi_\mu, c}^\delta \otimes V_{\delta \xi_\lambda, c}^\eta) \quad (34)$$

which has the same expression as $B_{\xi_\mu \xi_\nu, e_\sigma} : \bigoplus_\delta V_{\xi_\nu \xi_\mu, c}^\delta \rightarrow \bigoplus_\delta V_{\xi_\nu \xi_\mu, c}^\delta$, as though the fusion space is extended, the basis in the extended fusion space should keep diagonalized under the braiding of ξ_μ around ξ_ν , as shown in Fig.4.

Then $\Theta_{\mu\nu\lambda,\sigma}$ can be expressed through:

$$e^{i\Theta_{\mu\nu\lambda,\sigma}} I = (\tilde{B}_{\xi_\nu \xi_\mu \xi_\lambda, e_\sigma}^\eta)^{-1} (B_{\xi_\mu \xi_\nu, e_\sigma})^{-1} \tilde{B}_{\xi_\nu \xi_\mu \xi_\lambda, e_\sigma}^\eta B_{\xi_\mu \xi_\nu, e_\sigma} \quad (35)$$

where I is the identity matrix in the vector space $\bigoplus_\delta (V_{\xi_\nu \xi_\mu, c}^\delta \otimes V_{\delta \xi_\lambda, c}^\eta)$.

Now we are ready to go back to the proof. For simplicity we only consider $m = 1$. And from constraint (14), we have $\Theta_{00i,j} = \Theta_{iii,j}$. Firstly we show that the non-Abelian statistics in Kitaev-chain layer (i.e. the Ising type statistics) must have $\Theta_{00i,j} = \pi$: Do a dimension

reduction for the gauged Ising type FSPT system from 3D to 2D by choosing ξ_j as the base loop, and condense all the bosonic quasiparticles (as the Ising type statistics is irrelevant to the bosonic matter). The remaining 2D quasiparticles are exactly the Ising anyons: a vortex carrying one majorana mode σ , a fermion ψ and vacuum 1, which satisfies:

$$e^{i\Theta_{\sigma\sigma\sigma}} I = (\tilde{B}_{\sigma\sigma\sigma}^\sigma)^{-1} (B_{\sigma\sigma})^{-1} \tilde{B}_{\sigma\sigma\sigma}^\sigma B_{\sigma\sigma} = e^{i\pi} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad (36)$$

where we have $\Theta_{\sigma\sigma\sigma} = \pi$. And the 3D topological invariants $\Theta_{iii,j}$ is exactly equal to the 2D one $\Theta_{\sigma\sigma\sigma}$ after dimension reduction and the condensation of all bosons, i.e. $\Theta_{00i,j} = \Theta_{iii,j} = \Theta_{\sigma\sigma\sigma} = \pi$. Secondly we show that $\Theta_{00i,j} = \pi$ corresponds uniquely to the Ising type statistics: From constraint (14), when $m = 1$, $\Theta_{00i,j}$ can only take values 0 or π ; when m is even, $\Theta_{00i,j}$ vanishes. We assume the types of non-Abelian statistics in our gauged FSPT system contain only: (1) Ising type in Kitaev-chain layer (2) fermionic type in complex fermion layer (3) bosonic type in BSPT layer. Solving the constraints as listed in Supplementary Material, and examining the generating phases by mapping to 2D model constructions after dimension reduction²⁵, we find that to construct the generating phase $\Theta_{00i,j} = \pi$, there always exist loops with quantum dimension $\sqrt{2}$, which is the unique property of Ising anyons in the Kitaev-chain layer.

The second statistics-type indicator $\Theta_{fi,j} = \frac{N_{0i}}{\gcd(2, N_i)} \Theta_{0i,j} \neq 0$ ($i \neq j$) is proposed and proven in Ref.7. Combining the results in Ref.25 and Ref.7, we infer that $\Theta_{fij,k} = \Theta_{ij,k} = m\Theta_{0ij,k} \neq 0$ is the indicator for the non-Abelian statistics in the complex fermion layer. Finally $\Theta_{ijk,l} \neq 0$ is obviously the indicator for the BSPT layer by the definition of the topological invariant $\Theta_{\mu\nu\lambda,\sigma}$. However, if we consider a special example $G_f = \mathbb{Z}_4^f \times \mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$, where $\Theta_{0ij,k} = \pi$ and $\Theta_{fij,k} = 2\Theta_{0ij,k} = 0$ should still belong to the non-Abelian statistics in BSPT layer. Hence we conclude that $\Theta_{ijk,l} \neq 0$ and $\{\Theta_{fij,k} = 0, \Theta_{0ij,k} \neq 0\}$ are both the indicators for the non-Abelian statistics in BSPT layer.

C. Example 1: $\mathbb{Z}_2^f \times \mathbb{Z}_2 \times \mathbb{Z}_8$

Firstly, we recall the stacking group classification of FSPT phases:

$$H_{stack} = A \times \prod_i B_i \times \prod_{i < j} C_{ij} \quad (37)$$

where from Table I we know that: A protected by $\mathbb{Z}_2^f$ is trivial, B_1 and B_2 protected by $\mathbb{Z}_2^f \times \mathbb{Z}_2$ and $\mathbb{Z}_2^f \times \mathbb{Z}_8$ respectively are trivial, while C_{12} protected by $\mathbb{Z}_2^f \times \mathbb{Z}_2 \times \mathbb{Z}_8$ is nontrivial. Therefore the classification of FSPT phases

for the symmetry group is $H_{stack} = C_{12}$. Then we explicitly show the calculation of C_{12} : Invoking the known 2D results and combining with the 3D constraints $N_\sigma \Theta_{\mu,\sigma} = 0$, $N_\sigma \Theta_{\mu\nu,\sigma} = 0$, $N_\sigma \Theta_{\mu\nu\lambda,\sigma} = 0$, the generating phases for the subsets (C1), (C2), (C3), (C4) and (C5) are:

$$(\Theta_{ij,0}, \Theta_{0ij,0}) = \left(\frac{2\pi}{N_{ij}}, 0\right) \times a + \left(0, \frac{2\pi}{N_{0ij}}\right) \times b = (\pi a, \pi b) \quad (38)$$

$$(\Theta_{ij,i}, \Theta_{0ij,i}) = \left(\frac{2\pi}{N_{ij}}, 0\right) \times c + \left(0, \frac{2\pi}{N_{0ij}}\right) \times d = (\pi c, \pi d) \quad (39)$$

$$(\Theta_{ij,j}, \Theta_{0ij,j}) = \left(\frac{2\pi}{N_{ij}}, 0\right) \times e + \left(0, \frac{2\pi}{N_{0ij}}\right) \times f = (\pi e, \pi f) \quad (40)$$

$$\begin{aligned} (\Theta_{i,j}, \Theta_{0i,j}, \Theta_{00i,j}) &= \left(\frac{\pi}{2N_i}, -\frac{\pi}{N_{0i}}, \pi\right) \times g + \left(0, \frac{4\pi}{N_{0i}}, 0\right) \\ &= \left(\frac{\pi}{4}, -\frac{\pi}{2}, \pi\right) g \end{aligned} \quad (41)$$

$$\begin{aligned} (\Theta_{j,i}, \Theta_{0j,i}, \Theta_{00j,i}) &= \left(\frac{\pi}{N_j}, \frac{2\pi}{N_{0j}}, 0\right) \times N_j h + \left(0, \frac{4\pi}{N_{0j}}, \pi\right) \times i \\ &= (\pi h, 0, \pi i) \end{aligned} \quad (42)$$

where $a, b, c, d, e, f, g, h, i$ are all integers. By the constraint $\Theta_{0ij,0} = \Theta_{00i,j} = -\Theta_{0ij,i} = -\Theta_{00j,i} = -\Theta_{0ij,j}$, we have $b = d = f = i \pmod{2}$. By the constraint $\Theta_{ij,0} + \Theta_{0j,i} + 4\Theta_{0i,j} = 0$, we have $a = 0 \pmod{2}$. By the constraint $\Theta_{ij,i} = -4\Theta_{i,j}$, we have $c = -g \pmod{8}$. By the constraint $\Theta_{ij,j} = -\Theta_{j,i}$, we have $e = -h \pmod{2}$.

Combining all the constraints: $a = 0 \pmod{2}$, $b = d = f = g = i = -c \pmod{8}$, $e = -h \pmod{2}$, i.e. the generating phases are:

$$\begin{aligned} &(\Theta_{0ij,0}, \Theta_{ij,i}, \Theta_{00i,j}, \Theta_{0ij,j}, \Theta_{i,j}, \Theta_{0i,j}, \Theta_{00i,j}, \Theta_{00j,i}) \\ &= (\pi, \pi, \pi, \pi, \frac{\pi}{4}, -\frac{\pi}{2}, \pi, \pi) \end{aligned} \quad (43)$$

$$(\Theta_{ij,j}, \Theta_{j,i}) = (\pi, \pi) \quad (44)$$

while all other topological invariants vanish:

$$\Theta_{0,0} = 0 \quad (45)$$

$$\begin{aligned} &(\Theta_{0,i}, \Theta_{i,0}, \Theta_{0i,0}, \Theta_{00i,0}, \Theta_{i,i}, \Theta_{0i,i}, \Theta_{00i,i}) \\ &= (0, 0, 0, 0, 0, 0, 0) \end{aligned} \quad (46)$$

$$\begin{aligned} &(\Theta_{0,j}, \Theta_{j,0}, \Theta_{0j,0}, \Theta_{00j,0}, \Theta_{j,j}, \Theta_{0j,j}, \Theta_{00j,j}) \\ &= (0, 0, 0, 0, 0, 0, 0) \end{aligned} \quad (47)$$

$$(\Theta_{ij,0}, \Theta_{0j,i}) = (0, 0) \quad (48)$$

Hence in this case the classification is $\mathbb{Z}_8 \times \mathbb{Z}_2$, which is a $\mathbb{Z}_2$ complex fermion layer absorbed into a $\mathbb{Z}_2 \times \mathbb{Z}_2$ BSPT layer, together forming a $\mathbb{Z}_4 \times \mathbb{Z}_2$ classification, and then a $\mathbb{Z}_2$ Kitaev-chain layer again absorbed into the $\mathbb{Z}_4 \times \mathbb{Z}_2$ above, as the complex fermion layer indicator is $\Theta_{fi,j} = \Theta_{0i,j} = -\frac{\pi}{2}$.

Conveniently we can view the " $\mathbb{Z}_8$ " part of the classification being generated by:

$$\Theta_{i,j} = \left\{ \frac{\pi}{4}, \frac{\pi}{2}, \frac{3}{4}\pi, \pi, \frac{5}{4}\pi, \frac{3}{2}\pi, \frac{7}{4}\pi, 0 \right\} \quad (49)$$

where $\Theta_{i,j} = \{0, \pi\}$ correspond to Abelian BSPT phases, $\Theta_{i,j} = \{\frac{\pi}{2}, \frac{3}{2}\pi\}$ are Abelian FSPT phases (contain both BSPT layer and complex fermion layer), and $\Theta_{i,j} = \{\frac{\pi}{4}, \frac{3}{4}\pi, \frac{5}{4}\pi, \frac{7}{4}\pi\}$ are non-Abelian FSPT phases (contain all BSPT layer, complex fermion layer and Kitaev-chain layer). Recall that $\Theta_{00i,j} = \pi$ (m is odd) is the indicator of the Kitaev-chain layer. And the four non-Abelian FSPT phases all have $(\Theta_{00i,j}, \Theta_{00j,i}) = (\pi, \pi)$, which means that loops ξ_i and ξ_j each carry one unpaired Majorana mode simultaneously and both have quantum dimension $\sqrt{2}$, which is the origin of the non-Abelian statistics in Kitaev-chain layer. On the other hand, the " $\mathbb{Z}_2$ " part of the classification is generated by:

$$\Theta_{j,i} = \{0, \pi\} \quad (50)$$

where $\Theta_{j,i} = \pi$ is a non-trivial BSPT phase, and $\Theta_{j,i} = 0$ is a trivial BSPT phase.

We can also understand the 3D braiding statistics by doing a dimension reduction from 3D to 2D and applying the known model construction for 2D generating phases²⁵. Firstly we choose ξ_j always to be the base loop, and the 2D system after dimension reduction has symmetry $\mathbb{Z}_2^f \times \mathbb{Z}_2$, which has only one generating phase $(\Theta_i, \Theta_{0i}, \Theta_{00i}) = (\frac{\pi}{4}, -\frac{\pi}{2}, \pi)$, i.e. the subset (C4) in category C. And it can be realized by a two-layer model construction: the first layer a is a charge-2 superconductor with chiral central charge $-\frac{1}{2}$ (Ising type), while the second layer b is a charge-2 superconductor with chiral central charge $\frac{1}{2}$ (Ising type). The 2D vortex ξ_0 is composited by a unit-flux vortex in layer a and a unit-flux vortex in layer b , which therefore has quantum dimension 2. The 2D vortex ξ_i is composited only by a unit-flux vortex in layer b , which therefore has quantum dimension $\sqrt{2}$. As the quantum dimensions of loops are invariant under dimension reduction, we conclude that for non-Abelian FSPT phases, with ξ_j all being base loops, loop ξ_0 has quantum dimension 2 and loop ξ_i has quantum dimension $\sqrt{2}$.

Secondly we choose ξ_i always to be the base loop, and the 2D system after dimension reduction has symmetry $\mathbb{Z}_2^f \times \mathbb{Z}_8$, which has two generating phases $(\Theta_j, \Theta_{0j}, \Theta_{00j}) = (\frac{\pi}{8}, \pi, 0)$ and $(\Theta_j, \Theta_{0j}, \Theta_{00j}) = (0, 0, \pi)$, where the first one is trivialized to a $\mathbb{Z}_2$ BSPT in 3D, and both constitute the subset (C5) in category C. Only the second generating phase corresponds to non-Abelian statistics and can be realized by a three-layer

model construction: the first layer a is a charge-2 superconductor with chiral central charge $-\frac{1}{2}$ (Ising type), the second layer b is a charge-8 superconductor with chiral central charge 0 (Abelian layer), and the third layer c is a charge-2 superconductor with chiral central charge $\frac{1}{2}$ (Ising type). The 2D vortex ξ_0 is composited by a unit flux in layer a , four times of unit flux in layer b , and a unit flux in layer c , which therefore has quantum dimension 2. The 2D vortex ξ_j is composited only by a unit flux in layer b and a unit flux in layer c , which therefore has quantum dimension $\sqrt{2}$.

Thirdly we do not specify the base loop, and let the 2D system after dimension reduction have the full symmetry $\mathbb{Z}_2^f \times \mathbb{Z}_2 \times \mathbb{Z}_8$, which has two generating phases $(\Theta_{ij,0}, \Theta_{0ij,0}) = (\pi, 0)$ and $(\Theta_{ij,0}, \Theta_{0ij,0}) = (0, \pi)$ (or $(\Theta_{ij,i}, \Theta_{0ij,i}) = (\pi, 0)$ and $(\Theta_{ij,i}, \Theta_{0ij,i}) = (0, \pi)$), $(\Theta_{ij,0}, \Theta_{0ij,0}) = (\pi, 0)$ and $(\Theta_{ij,0}, \Theta_{0ij,0}) = (0, \pi)$, i.e. the subset (C1) (or (C2), (C3)) in category C. Only the second generating phase corresponds to non-Abelian statistics and can be realized by a four-layer model construction: the first layer a is a charge-2 superconductor with chiral central charge $-\frac{1}{2}$ (Ising type), the second layer b is a charge-2 superconductor with chiral central charge 0 (Abelian layer), the third layer c is a charge-8 superconductor with chiral central charge 0 (Abelian layer), and the fourth layer d is a charge-2 superconductor with chiral central charge $\frac{1}{2}$ (Ising type). The 2D vortex ξ_0 is composited by a unit flux in layer a , a unit flux in layer b , four times of unit flux in layer c , and a unit flux in layer d , which therefore has quantum dimension 2. The vortex ξ_i is composited by a unit flux in layer b and a unit flux in layer d , which therefore has quantum dimension $\sqrt{2}$. Similarly The vortex ξ_j is composited by a unit flux in layer c and a unit flux in layer d , which also has quantum dimension $\sqrt{2}$. In conclusion, we find that no matter how we do the dimension reduction, the quantum dimensions of the loops coincide, i.e. in our three-loop braiding system with full symmetry $\mathbb{Z}_2^f \times \mathbb{Z}_2 \times \mathbb{Z}_8$, for those non-Abelian FSPT phases, the loop ξ_0 has quantum dimension 2, and loops ξ_i and ξ_j both have quantum dimension $\sqrt{2}$, which means that loops ξ_i and ξ_j each carries an unpaired Majorana mode.

D. Example 2: $\mathbb{Z}_2^f \times \mathbb{Z}_4 \times \mathbb{Z}_4$

Similarly in the stacking group classification, A, B_1, B_2 are all trivial, and we only need to consider $H_{stack} = C_{12}$. Invoking the known 2D results and combining with the 3D constraints $N_\sigma \Theta_{\mu,\sigma} = 0$, $N_\sigma \Theta_{\mu\nu,\sigma} = 0$, $N_\sigma \Theta_{\mu\nu\lambda,\sigma} = 0$, the generating phases for the subsets (C1), (C2), (C3), (C4) and (C5) are:

$$\begin{aligned} (\Theta_{ij,0}, \Theta_{0ij,0}) &= \left(\frac{2\pi}{N_{ij}}, 0 \right) \times \frac{N_{ij}}{2} a + \left(0, \frac{2\pi}{N_{0ij}} \right) \times \frac{N_{0ij}}{2} b \\ &= (\pi a, \pi b) \end{aligned} \quad (51)$$

$$(\Theta_{ij,i}, \Theta_{0ij,i}) = \left(\frac{2\pi}{N_{ij}}, 0\right) \times c + \left(0, \frac{2\pi}{N_{0ij}}\right) \times d = \left(\frac{\pi}{2}c, \pi d\right) \quad (52)$$

$$(\Theta_{ij,j}, \Theta_{0ij,j}) = \left(\frac{2\pi}{N_{ij}}, 0\right) \times e + \left(0, \frac{2\pi}{N_{0ij}}\right) \times f = \left(\frac{\pi}{2}e, \pi f\right) \quad (53)$$

$$\begin{aligned} (\Theta_{i,j}, \Theta_{0i,j}, \Theta_{00i,j}) &= \left(\frac{\pi}{N_i}, \frac{2\pi}{N_{0i}}, 0\right) \times 2g + \left(0, \frac{2\pi}{N_{0i}}, \pi\right) \times h \\ &= \left(\frac{\pi}{2}g, \pi h, \pi h\right) \end{aligned} \quad (54)$$

$$\begin{aligned} (\Theta_{j,i}, \Theta_{0j,i}, \Theta_{00j,i}) &= \left(\frac{\pi}{N_j}, \frac{2\pi}{N_{0j}}, 0\right) \times 2l + \left(0, \frac{2\pi}{N_{0j}}, \pi\right) \times m \\ &= \left(\frac{\pi}{2}l, \pi m, \pi m\right) \end{aligned} \quad (55)$$

By the constraint $\Theta_{0ij,0} = \Theta_{00i,j} = -\Theta_{0ij,i} = -\Theta_{00j,i} = -\Theta_{0ij,j}$, we have $b = d = f = h = m \pmod{2}$. By the constraint $\Theta_{ij,0} + \Theta_{0j,i} + \Theta_{0i,j} = 0$, we have $a = 0 \pmod{2}$. By the constraint $\Theta_{ij,i} = -\Theta_{i,j}$, we have $c = -g \pmod{4}$. By the constraint $\Theta_{ij,j} = -\Theta_{j,i}$, we have $e = -l \pmod{4}$.

Combining all the constraints: $a = 0 \pmod{2}$, $b = d = f = h = m \pmod{2}$, $c = -g \pmod{4}$, $e = -l \pmod{4}$, i.e. the generating phases are:

$$\begin{aligned} &(\Theta_{0ij,0}, \Theta_{0ij,i}, \Theta_{0ij,j}, \Theta_{0i,j}, \Theta_{00i,j}, \Theta_{0j,i}, \Theta_{00j,i}) \\ &= (\pi, \pi, \pi, \pi, \pi, \pi, \pi) \end{aligned} \quad (56)$$

$$(\Theta_{ij,i}, \Theta_{i,j}) = \left(\frac{\pi}{2}, \frac{\pi}{2}\right) \quad (57)$$

$$(\Theta_{ij,j}, \Theta_{j,i}) = \left(\frac{\pi}{2}, \frac{\pi}{2}\right) \quad (58)$$

while all other topological invariants vanish.

Hence in this case the classification is $\mathbb{Z}_4 \times \mathbb{Z}_4 \times \mathbb{Z}_2$, which is a $\mathbb{Z}_4 \times \mathbb{Z}_4$ BSPT simply stacking with a $\mathbb{Z}_2$ "Kitaev-chain layer absorbed in complex fermion layer", as the complex fermion layer indicator is $\Theta_{fi,j} = \Theta_{0i,j} = \pi$.

The " $\mathbb{Z}_2$ " part of the classification can be viewed to be generated by:

$$(\Theta_{0i,j}, \Theta_{00i,j}) = (\pi, \pi) \text{ or } (\Theta_{0j,i}, \Theta_{00j,i}) = (\pi, \pi) \quad (59)$$

while all other π valued topological invariants are related by the anti-symmetric constraint of $\Theta_{\mu\nu\lambda,\sigma}$. We do a dimension reduction by always choosing ξ_j as the base loop, and the 2D system has symmetry $\mathbb{Z}_2^f \times \mathbb{Z}_4$. We find that $(\Theta_{0i}, \Theta_{00i}) = (\pi, \pi)$ is exactly the second generating phase for this 2D FSPT system, which can be realized by a three-layer model construction²⁵: the first layer a is a charge-2 superconductor with chiral central charge

$\frac{3}{2}$ (Ising type), the second layer b is a charge-4 superconductor with chiral central charge -2 (Abelian layer), and the third layer c is a charge-2 superconductor with chiral central charge $\frac{1}{2}$ (Ising type). The 2D vortex ξ_0 is composited by a unit flux in layer a , two times of unit flux in layer b , and a unit flux in layer c , which therefore has quantum dimension 2. The vortex ξ_i is composited by a unit flux in layer b and a unit flux in layer c , which therefore has quantum dimension $\sqrt{2}$. As the quantum dimensions of the loops are invariant under dimension reduction, and the symmetry groups of ξ_i and ξ_j are both $\mathbb{Z}_4$ so that it is free to choose which is $\mathbb{Z}_{N_i}$ and which is $\mathbb{Z}_{N_j}$, we conclude that in our gauged 3D FSPT systems, loop ξ_0 has quantum dimension 2 and both loop ξ_i and ξ_j have quantum dimension $\sqrt{2}$.

Then we can again check the quantum dimension of loops by doing the dimension reduction without specifying the base loop, and the 2D system has the full symmetry $\mathbb{Z}_2^f \times \mathbb{Z}_4 \times \mathbb{Z}_4$. The second non-Abelian generating phase $(\Theta_{ij,0}, \Theta_{0ij,0}) = (0, \pi)$ (or $(\Theta_{ij,i}, \Theta_{0ij,i})$, $(\Theta_{ij,j}, \Theta_{0ij,j})$) can also be realized by a four-layer construction similarly as in the first example. Then the quantum dimension of ξ_0 will still be found as 2, and the quantum dimensions of ξ_i and ξ_j as both $\sqrt{2}$. Therefore in our construction the nontrivial non-Abelian FSPT phase in the $\mathbb{Z}_2$ classification is due to the unpaired Majorana modes attached on ξ_i and ξ_j .

VI. CONCLUSION

In summary, we obtain the classification of 3D FSPT phases with finite unitary Abelian symmetry, by gauging the symmetry and studying the topological invariants $\{\Theta_{\mu,\sigma}, \Theta_{\mu\nu,\sigma}, \Theta_{\mu\nu\lambda,\sigma}\}$ defined through the braiding statistics of loop-like excitations in certain three-loop braiding processes. And we compare this result with the classification obtained by the layer construction method in Ref²³, from which we can realize any set of values of the topological invariants, each corresponds to a distinguished FSPT phase, by the layer-construction. Specially we argue that the non-Abelian statistics in the Kitaev-chain layer is due to the unpaired Majorana modes attached on loops. However, for further study, it remains unknown how to apply the braiding statistics method to SPT phases with antiunitary symmetry such as the time reversal symmetry, as we do not know how to gauge an antiunitary symmetry. And it is expected to generalize the Abelian symmetry groups to generally non-Abelian symmetry groups, including the 3D space groups.
