## Abstract

**Background** Emerging evidence shows that abnormal expression of long non-coding RNA is involved in the occurrence and development of various tumors. LncRNA MONC is abnormally expressed in head and neck squamous cell carcinoma, lung cancer, colorectal cancer, and acute megakaryocytic leukemia, but the biological function and potential regulatory mechanism of MONC in endometrial cancer stem cells (ECSCs) and endometrial cancer cells (ECCs) have not been studied. **Methods** We used qRT-PCR to detect the expression of MONC, miR-636 and GLCE in normal human endometrial tissues and endometrial carcinoma tissues. Luciferase assay was used to verify the binding sites between MONC and miR-636 and between miR-636 and GLCE. The double fluorescence in situ hybridization was used to locate MONC and miR-636 in cells. Endometrial cancer stem cells were obtained by Flow cytometry sorting assay. Sphere formation assay, CCK-8 assay, transwell invasion assay, cell cycle analysis and apoptosis assay were used to detect the effects of MONC/miR-636/GLCE axis on the malignant biological behavior of ECSCs and endometrial carcinoma cells (ECCs). The effect of MONC on the epithelial-to-mesenchymal transition (EMT) process was detected using western blot. Finally, we conducted in vivo verification through Tumor xenografts in nude mice. **Results** In this study, we aimed to explore the tumor suppressive effect and mechanism of MONC in regulating ECSCs and ECCs. We found MONC is low expression in endometrial carcinoma (EC), MONC and miR-636 are relatively co-localized in the cytoplasm. MONC directly inhibits the malignant biological behavior of ECSCs and ECCs by directly inhibiting miR-636. Simultaneously, miR-636 may indirectly reduce the expression of MONC. Down-regulation of miR-636 may promote GLCE expression by targeting the 3'-untranslated region (UTR) of the downstream gene GLCE, thereby inhibiting the progression of ECSCs. MONC combined with miR-636 inhibited tumor epithelial-to-mesenchymal transition (EMT) process. In addition, we verified the tumor suppressive effect of MONC in nude mice, miR-636 can rescue the tumor suppressive effect of overexpressing MONC. **Conclusions** In conclusion, this study shows that MONC inhibits the malignant phenotypes of ECSCs and ECCs by regulating the miR-636/GLCE axis. The MONC/miR-636/GLCE axis may provide novel treatment avenues for human EC.

## Background

Endometrial carcinoma (EC) is one of the three major malignant tumors in gynecology, with 61,880 new cases each year in the United States, second only to breast cancer, lung cancer, bronchial cancer, and colorectal cancer. There are 12,160 deaths each year, second only to lung cancer, bronchial cancer, breast cancer, colorectal cancer, pancreatic cancer, and ovarian cancer<sup>[1]</sup>. Risk factors for EC include elevated estrogen levels (caused by obesity, diabetes, and high-fat diets), premature menarche, non-parturients, late desperate age, Lynch syndrome, grade  $\geq$  55 years old, and using tamoxifen<sup>[2]</sup>.

Cancer stem cells (CSCs) are a class of cells that have the unique characteristics of self-renewal and the ability to differentiate into heterogeneous lineages of cancer cells<sup>[3, 4]</sup>. CSCs can initiate tumor formation and promote tumor cell proliferation, while differentiation of component tumor cells plays a vital role in the occurrence, development, metastasis, recurrence, and drug resistance of malignant tumors<sup>[5, 6]</sup>. In our previous research, we used serum-free suspension culture to isolate endometrial cancer stem cells (ECSCs) from Ishikawa cells<sup>[7]</sup>.

Long non-coding RNA (LncRNA) is a non-coding RNA with a length of more than 200 nucleotides. In recent years, LncRNA has been found to be an important biological marker for the diagnosis of tumors and their prognosis<sup>[8]</sup>. Increasing studies show that LncRNA plays a vital role in the occurrence and development of tumors, including EC, and LncRNA is dysregulated in EC and is closely related to tumorigenesis, metastasis, and chemoresistance<sup>[9]</sup>. However, LncRNA is rarely studied in ECSCs. MONC, mir-99a-let-7c cluster host gene, also known as MIR99AHG, is a good prognostic indicator of head and neck squamous cell carcinoma<sup>[10]</sup>, lung squamous cell carcinoma<sup>[11]</sup>, and colorectal cancer<sup>[12]</sup>. In acute megakaryoblastic leukemia, MONC acts as an oncogene to promote leukemia growth in AMKL cell lines and primary patient samples<sup>[13]</sup>. However, MONC has not been studied in EC and ECSCs.

MicroRNA (miRNA) is a non-coding RNA approximately 20–24 nucleotides in length, which can induce translational inhibition or degradation of target mRNA to inhibit gene expression<sup>[14]</sup>. Abnormally expressed miRNAs are associated with tumorigenesis, development, and response to treatment<sup>[15]</sup>. miR-636 has been studied in tumors in recent years. Studies have shown that miR-636 is abnormally expressed in bladder cancer and liver cancer<sup>[16, 17]</sup>. However, miR-636 has not been studied in EC and ECSCs.

In this study, we aimed to study the expression level of MONC and its interaction with miR-636 in endometrial carcinoma tissues and ECSCs. It was found that miR-636 targeted MONC in a sequence-specific manner in the cytoplasm, suggesting that there may be mutual inhibition between miR-636 and MONC. To study the potential mechanism in this process, the effect of MONC on miR-636-induced GLCE regulation and its effect on epithelial-mesenchymal transition (EMT) were also studied. Our findings shed light on new molecular mechanisms for the progression of EC and provide potential treatment options.

## Materials And Methods

### Human tissue specimens

All endometrial carcinoma tissue samples and normal endometrial tissue samples were obtained from patients undergoing total hysterectomy at Shengjing Hospital of China Medical University. The diagnosis of EC was evaluated by two experienced clinical pathologists based on FIGO for histological diagnosis and tumor grade. No patients received chemotherapy, radiotherapy, hormones, or treatment before surgery. All patients obtained informed consent and had been approved by the Ethics Committee of Shengjing Hospital, China Medical University (2018PS251K).

## ECSCs, cell lines, and cell culture

ECSCs were cultured in serum-free medium, DMEM/F12 (1:1) (Corning, New York, USA) containing 2% B27 Supplement (Gibco, New York, USA), 20 ng/ml EGF (PeproTech, New Jersey, USA), 20 ng/ml bFGF (PeproTech), and 1% penicillin-streptomycin (Invitrogen, Carlsbad, California, USA). Ishikawa cell line (Shanghai huiying, Shanghai, China) and HEC-1A cell line (Genechem, Shanghai, China) were cultured in  $\alpha$ -MEM medium (Bioind, Kibbutz Beit Haemek, Israel) and McCoy's 5A medium (Bioind), respectively. The medium contained 10% fetal bovine serum (FBS) (Bioind) and 1% penicillin-streptomycin (Invitrogen). HEK293T cells were cultured in DMEM/high-glucose medium (Corning). The medium contained 10% FBS (Bioind) and 1% penicillin-streptomycin (Invitrogen). All cells were cultured in a humidified incubator at 37 ° C with 5% CO<sub>2</sub>.

## RNA extraction, reverse transcription, and qRT-PCR

Total RNA was extracted from tissues and cells using TRIzol reagent (Takara, Beijing, China). The complementary DNAs (cDNAs) for the lncRNAs and mRNAs of interest were reverse-transcribed from 2  $\mu$ g total RNA using PrimeScript RT-polymerase (Takara). The cDNAs for the miRNAs of interest were synthesized from 1  $\mu$ g total RNA using miRNA 1st Strand cDNA Synthesis SuperMix (Vazyme, Nanjing, China). We performed qRT-PCR using SYBR-Green Premix (Takara), miRNA Universal SYBR® qPCR Master Mix (Vazyme), and specific PCR primers (Sangon Biotech, Shanghai, China). Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and U6 were used as internal controls. We observed the expression of lncRNA, mRNA, and miRNA by calculating  $2^{-\Delta\Delta CT}$ . Primer sequences are summarized in Table 1.

Table 1  
Primer Sequences

Gene name	Primer Sequence
MONC	Forward: CCAGACTTGTGCGCACGGAT
	Reverse: AATGCACAGCAATCAGTTCTC

## Western blot

Protein was extracted from tissues and cells using RIPA Lysis Buffer (Beyotime Biotechnology, Shanghai, China) and phenylmethanesulfonyl fluoride (PMSF) (Beyotime Biotechnology). Protein denaturation was performed after adding SDS-PAGE Sample Loading Buffer. Denatured proteins were separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to polyvinylidene fluoride membranes (Millipore, USA). Membranes were blocked with 5% skim milk for 2 h and washed thrice with TBST. Membranes were then incubated with diluted primary antibodies for GLCE (Abcom, Cambridge, United Kingdom), Notch1 (Proteintech, Chicago, USA), Notch-1 Intracellular Domain (N1ICD) (R&D SYSTEMS, Minnesota, USA), Snail1 (Proteintech), E-cadherin (Proteintech), N-cadherin (Proteintech), and Vimentin (Proteintech) overnight at 4 °C, and washed thrice with TBST thereafter. Membranes were then incubated with corresponding secondary antibodies for 2 h, followed by washing thrice with TBST. The protein bands were visualized using BeyoECL Star (Beyotime Biotechnology) and Quantum One imaging software (Bio-Rad, California, USA), and normalized to the gray intensity of GAPDH.

## Transfection and generation of stably transfected cell line

MONC lentiviral overexpression plasmid and lentiviral knockdown plasmid were purchased from GeneChem (Shanghai, China). ECSCs and Ishikawa cells were then transfected at a multiplicity of infection (MOI) of 20, while an MOI of 10 was used for HEC-1A cells. MiR-636 agomir and antagomir were purchased from GenePharma (Shanghai, China), and GLCE overexpression plasmid and knockdown plasmid were purchased from GeneChem (Shanghai). All cells were transfected with jetPRIME® *in vitro* DNA and siRNA Transfection Reagent (PolyPlus-transfection, France) for subsequent experiments. The relevant sequence can be found in Table 2.

Table 2  
Sequences of lentivirus, agomir/antagomir, and plasmid

Name	Sequence

## Flow cytometry sorting assay

According to our previous research results <sup>[7]</sup>, we performed flow cytometry sorting assay. After Ishikawa cells were cultured and passaged in serum-free medium, the cell pellet was collected and washed once with phosphate-buffered saline (PBS). Cells were resuspended ( $10^7$  cells in 100  $\mu$ l PBS) and labeled with APC Mouse Anti-Human CD133 (BD Biosciences, New Jersey, USA) and PerCP-Cy7M 5.5 Mouse Anti-Human CD44 (BD Biosciences). Following incubation for 10 minutes in the dark, cells were washed with PBS, and the supernatant was discarded after centrifugation. Thereafter, cells were resuspended in PBS, and flow sorted using the BD FACS Aria<sup>TM</sup> III Cell Sorter (BD Biosciences).

## Sphere formation assay

After obtaining ECSCs in the above manner, cells were cultured in DMEM/F12 (1:1) serum-free medium containing 2% B27 additive, 20 ng/ml EGF, 20 ng/ml bFGF, and 1% penicillin-streptomycin. After culture for 3-5 days, 5000 cells were seeded in ultra-low-attachment 6-well plates (Corning, USA) and cultured for 7 days further. Cells were imaged under an inverted fluorescence microscope and an image acquisition system. The sphere diameter was measured at the time of inoculation and 7 days, respectively.

## CCK-8 assay

Cells were cultured in 96-well plates (Guangzhou Jet Bio-Filtration Co., Ltd.), CCK-8 reagent (10  $\mu$ l) (Dojindo, Japan) was added to each well, and then incubated at 37 °C with 5% CO<sub>2</sub> for 3 hours. The OD450 value of each well was determined using a microplate reader. Detection was performed at 12 h and 72 h after treatment.

## Transwell invasion assay

Transwell filter inserts (8  $\mu$ m pore size; Corning) were pre-coated with Matrigel at 37 °C for 30 minutes. Complete medium (500  $\mu$ l) was added to each well of the 24-well plate, and pure medium cell suspension (200  $\mu$ l) was added to the chamber. After incubation for 24 hours, cells were fixed with 4% poly-oxymethylene for 30 minutes, then stained with 0.1% crystal violet for 30 minutes. Cells were imaged under an inverted fluorescence microscope and an image acquisition system (Nikon, Japan).

## Cell cycle analysis

After cell transfection,  $10^6$  cells were collected from each group. After washing once in PBS, cells were fixed in 70% ethanol at 4 °C overnight. After washing once in PBS, cells were resuspended in 500  $\mu$ l PBS, followed by the addition of 10  $\mu$ l RNase A and 5  $\mu$ l propidium iodide, then incubated at 37 °C for 30 minutes. Flow cytometry (BD FACSCalibur, New Jersey, USA) was used to evaluate the proportion of cells at different stages of the cell cycle.

## Apoptosis assay

After cell transfection,  $10^6$  cells were collected from each group. After washing once in PBS, cells were stained with PE Annexin V and 7AAD using PE Annexin V Apoptosis Detection (BD Pharmingen™, New Jersey, USA) at room temperature for 15 minutes. We used flow cytometry (BD FACSCalibur, New Jersey, USA) to evaluate the proportion of apoptotic cells.

## Fluorescence *in situ* hybridization

DNA oligo probes (GenePharma) labeled with FAM for MONC (5'FAM-CAATCAGTTCCTCACATATTAGTCTAAGTCCTCTTTATAATTGAAGAAACATTCTTGTACTGGCTTTATGGGCATTCTTTCAATACTTTCAATGTTAAGAGGCCTTATT-3') and SA-Biotin for miR-636 (5'Biotin-TGCGGGCGGGACGACGAAGCACA-3') were used in the fluorescence *in situ* hybridization (FISH) assays, wherein the nuclei were counterstained with 4,6-diamidino-2-phenylindole. All procedures were performed in accordance with the manufacturer's instructions (GenePharma), and all images were acquired using a confocal laser-scanning microscope (CI: Nikon, Tokyo, Japan).

## Luciferase assay

The bioinformatics website, RNAhybrid, was used to predict the potential binding sites between MONC and miR-636. MONC wild-type and mutant dual-luciferase reporter vectors were purchased from Liaoning Baihaobio Biotech Co., Ltd. (Liaoning, China), and co-transfected with miR-636 agomir or NC (GenePharma, Shanghai). The bioinformatics website, miRDB, was used to predict the potential binding sites between miR-636 and GLCE. GLCE wild-type and mutant dual-luciferase reporter vectors were purchased from Liaoning Baihaobio Biotech Co., Ltd. (Liaoning, China), and co-transfected with miR-636 agomir or NC. A dual-luciferase reporter gene detection system (Promega, Madison, WI, USA) was used to detect luciferase activity.

## Tumor xenografts in nude mice

Transfected cells were evaluated *in vivo* in nude mice. We conducted experiments in strict accordance with a protocol approved by the Administrative Panel on Laboratory Animal Care of the Shengjing Hospital (2018PS136K). Nude mice were purchased from HFK Bioscience (Beijing, China), and all were 4-week-old BALB/C athymic nude mice. Each mouse was injected with  $5 \times 10^6$  cells at the armpit. The tumor volume was calculated according to the following formula: tumor volume ( $\text{mm}^3$ ) = length  $\times$  width<sup>2</sup>/2. The experiment was conducted in compliance with the Institutional Animal Care and Use Committee standards. When the mice developed tumor metastasis, lethargy, weight loss  $\geq 20\%$ , or other signs of discomfort that met the IACUC criteria, the mice were sacrificed by cervical dislocation.

## Statistical analysis

Data are expressed as Mean  $\pm$  Standard Error of Mean (SEM). All statistical analyses were performed using GraphPad Prism 8.0 Software (La Jolla, CA, USA) and SPSS version 22.0 software (Abbott Laboratories, Chicago, IL, USA) through two-sided Student's *t*-test or one-way analysis of variance (ANOVA). Differences were considered statistically significant at  $P < 0.05$ .

## Results

### MONC exhibits low expression in EC as a tumor suppressor gene

By quantitative real-time polymerase chain reaction (qRT-PCR) detection, compared with normal human endometrial tissue, MONC exhibited low expression in human endometrial carcinoma tissue (Fig. 1A). Clinical pathological analysis showed that MONC expression was related to the depth of invasion and FIGO Stage (Table 3). To determine the effect of MONC on ECSCs, we used LV-MONC, LV-MONC-RNAi, and their corresponding negative controls to construct stable lentiviral ECSCs, and Ishikawa and HEC-1A cell lines. Transfection efficiency was verified using qRT-PCR. A lentiviral vector (LV-MONC-RNAi (67379-1)) with the best knockdown effect was selected for subsequent experiments (Figure S1A).

Table 3  
Relationship between MONC expression and pathologic tumor parameters

Clinical parameters	n	The expression of MONC (Mean ± SEM)	P
Differentiation			0.098
High + High-Middle	35	0.360 ± 0.036	
Middle + Middle-Low + Low	25	0.467 ± 0.056	
Invasion depth			0.002 *
<1/2	40	0.473 ± 0.041	
≥ 1/2	20	0.268 ± 0.035	
FIGO Stage			0.007 *
I	52	0.438 ± 0.032	
II + III + IV	8	0.189 ± 0.088	
Age, y			0.241
<60	34	0.438 ± 0.046	
≥ 60	26	0.362 ± 0.042	

Based on previous research by our team, in order to extract ECSCs from endometrial carcinoma cells (ECCs), we used DMEM/F12 (1:1) serum-free medium containing 2% B27 supplement, 20 ng/ml EGF, 20 ng/ml bFGF, and 1% penicillin-streptomycin for Ishikawa cells to form mammospheres. Post-sphere formation, Ishikawa cells were labeled with CD44 (PerCP-Cy7M5.5 Mouse Anti-Human) and CD133 (APC Mouse Anti-Human), ECCs positive for both CD44 and CD133 were obtained using flow cytometry cell sorting. We obtained ECSCs via flow sorting, and these were used in subsequent experiments (Figure S1C-D).

In the CCK-8 cell proliferation assay, we observed reduced proliferation rates in the MONC overexpression group, while the MONC knocked down group appeared increased (Fig. 1B). In the ECSC sphere formation assay, we found that the growth rate of ECSC spheroids in the MONC overexpression group slowed down, while the growth rate of ECSC spheroids in the MONC knockdown group accelerated (Fig. 1C). Thereafter, the Transwell cell invasion assay revealed that overexpression of MONC inhibited the invasion of ECSCs, and Ishikawa and HEC-1A cells. Conversely, knockdown of MONC promoted the invasion of ECSCs, and Ishikawa and HEC-1A cells (Fig. 1D). Next, we examined the effects on overexpression and knockdown of MONC on the cell cycle and apoptosis of ECSCs, and Ishikawa and HEC-1A cells using flow cytometry. The results showed that MONC overexpression induced cell cycle arrest in the G0/G1 phase, while knockdown of MONC exerts the opposite effect (Fig. 1E). Overexpression of MONC promotes apoptosis, and knockdown of MONC inhibits apoptosis (Fig. 1F).

Therefore, MONC exhibits low expression in endometrial carcinoma as a tumor suppressor gene.

## Mir-636 exhibits high expression in EC as an oncogene, while MONC binds and negatively regulates miR-636

qRT-PCR revealed that miR-636 was highly expressed in human endometrial carcinoma tissue compared with normal human endometrial tissue (Fig. 2A). Clinical pathological analysis showed that the expression of MONC is related to invasion depth and FIGO Stage (Table 4). In addition, the expression of miR-636 was negatively correlated with the expression of MONC (Fig. 2B, Pearson's rank correlation method:  $r^2 = 0.0945$ ,  $P = 0.0169$ ).

Table 4  
Relationship between miR-636 expression and pathologic tumor parameters.

Clinical parameters	n	The expression of miR-636 (Mean ± SEM)	P
Differentiation			0.339
High + High-Middle	35	6.400 ± 0.779	
Middle + Middle-Low + Low	25	7.525 ± 0.844	
Invasion depth			0.037 *
<1/2	40	6.027 ± 0.601	
≥ 1/2	20	8.552 ± 1.167	
FIGO Stage			<0.001 *
I	52	6.039 ± 0.526	
II + III + IV	8	12.260 ± 1.710	
Age, y			0.987
<60	34	6.877 ± 0.818	
≥ 60	26	6.858 ± 0.800	

We used qRT-PCR to determine the expression of miR-636 in ECSCs, Ishikawa cells, and HEC-1A cells stably transfected with MONC overexpression and knockdown. The results showed that the expression of miR-636 decreased in the MONC overexpression group, while miR-636 expression increased in the MONC knockdown group (Fig. 2C). Next, we transfected ECSCs, Ishikawa cells, and HEC-1A cells with AgomiR-636, miR-636 antagomir, and corresponding negative controls. We detected the expression of MONC using qRT-PCR. The results showed that MONC expression decreased in the AgomiR-636 group and increased in the miR-636 antagomir group (Fig. 2D).

The double fluorescence in situ hybridization (D-FISH) showed that MONC and miR-636 were relatively co-localized in the cytoplasm of Ishikawa cells (Fig. 2E). A bioinformatics database (RNAhybrid) was used to predict the binding site between MONC and miR-636. In order to further study whether MONC is a functional target of miR-636, we co-transfected HEK-293T cells with MONC-WT and NC, and MONC-WT and miR-636. Thereafter, we performed a dual-luciferase reporter assay. The results showed that the relative luciferase activity of the MONC-WT + miR-636 group was lower than that of the MONC-WT + NC group, suggesting that there is a binding site between MONC and miR-636 (Fig. 2F). A MONC mutant vector was constructed, based on the predicted binding sites of the bioinformatics database (RNAhybrid). Next, we co-transfected HEK-293T cells with MONC-Mut and NC, and MONC-Mut and miR-636. Detection of the dual-luciferase reporter assay verified the binding site between MONC and miR-636 (Fig. 2F).

Therefore, we speculate that miR-636 is overexpressed in EC as an oncogene, MONC binds and negatively regulates miR-636, and there may be a feedback loop of mutual inhibition between MONC and miR-636.

## Knockdown of miR-636 mediates the tumor suppressive effect of MONC overexpression in ECSCs and ECCs

To determine whether miR-636 mediated tumor suppression via MONC overexpression, we first transfected miR-636 antagomir into ECSCs, Ishikawa cells, and HEC-1A cells stably overexpressing MONC. AgomiR-636 was transfected into MONC knocked down ECSCs, Ishikawa cells, and HEC-1A cells. We divided the experiments into six groups: Control, MONC (+), miR-636 (-), Stable NC, MONC(+) + miR-636(-), and MONC(-) + miR-636(+).

The CCK-8 cell proliferation assay indicated that the MONC(+) + miR-636(-) group exhibited the lowest proliferation rate, while the MONC(-) + miR-636(+) group exhibited the highest proliferation rate (Fig. 3A). The sphere formation assay demonstrated that miR-636 knockdown can inhibit the growth rate of ECSC spheroids. The MONC(+) + miR-636(-) group displayed the most obvious inhibitory effect on the growth rate of ECSC spheroids. The ECSC spheroids in the MONC(-) + miR-636(+) group displayed the fastest growth rate (Fig. 3B). According to the Transwell cell invasion experiment, we found that knockdown of miR-636 inhibited the invasion of ECSCs, Ishikawa cells, and HEC-1A cells. The MONC(+) + miR-636(-) group displayed the strongest invasion inhibitory effects in ECSCs, Ishikawa cells, and HEC-1A cells, while the MONC(-) + miR-636(+) group displayed the weakest invasion inhibitory effects (Fig. 3C). Thereafter, we employed flow cytometry to observe the cell cycle and apoptosis of ECSCs, Ishikawa cells, and HEC-1A cells after transfection. The results showed that AntagomiR-636 can induce cell cycle arrest at the G0/G1 phase, the MONC (+) + miR-636(-) group had the strongest ability to induce cell cycle arrest in the G0/G1 phase, and the MONC(-) + miR-636(+) group had the weakest ability (Fig. 3D). MiR-636 can inhibit apoptosis, and the MONC(+) + miR-636(-) group exhibited the strongest inhibitory effect on apoptosis, while the MONC(-) + miR-636(+) group exhibited the weakest (Fig. 3E).

Therefore, we believe that miR-636 can mediate tumor suppressive effects of MONC overexpression in ECSCs, Ishikawa cells, and HEC-1A cells, and that knockdown of MONC combined with overexpression of miR-636 have significant carcinoma-promoting effects in ECSCs and ECCs.

# GLCE exhibits low expression in EC as a tumor suppressor gene, and participates in the malignant progression of ECSCs induced by MONC-miR-636

qRT-PCR and western blot experiments revealed low expression of GLCE in human endometrial carcinoma tissue compared to normal human endometrial tissue (Fig. 4A). Clinical pathological analysis showed that the expression of GLCE is related to differentiation, invasion depth, and FIGO Stage (Table 5).

Table 5  
Relationship between GLCE expression and pathologic tumor parameters.

Clinical parameters	n	The expression of GLCE (Mean ± SEM)	P
Differentiation			0.003 *
High + High-Middle	35	0.193 ± 0.033	
Middle + Middle-Low + Low	25	0.371 ± 0.050	
Invasion depth			0.023 *
<1/2	40	0.316 ± 0.039	
≥ 1/2	20	0.170 ± 0.042	
FIGO Stage			0.012 *
I	52	0.297 ± 0.033	
II + III + IV	8	0.076 ± 0.021	
Age, y			0.104
<60	34	0.311 ± 0.042	
≥ 60	26	0.210 ± 0.043	

Using the bioinformatics database (miRDB), we observed that GLCE is a downstream target gene of miR-636. Therefore, we co-transfected HEK-293T cells with GLCE-WT and NC, and GLCE-WT and miR-636. We conducted dual-luciferase reporter tests and discovered that the relative luciferase activity of the GLCE-WT + miR-636 group was lower than that of the GLCE-WT + NC group, suggesting that there is a binding site between GLCE and miR-636 (Fig. 4D). A GLCE mutant vector was constructed based on the predicted binding sites of the bioinformatics database (miRDB), followed by co-transfection of GLCE-Mut and NC, and GLCE-Mut and miR-636. The dual-luciferase reporter test verified the binding site between MONC and miR-636 (Fig. 4D).

In order to investigate whether MONC could regulate miR-636 in EC as ceRNA of GLCE, western blot was used to determine the expression level of GLCE in ECSCs, Ishikawa cells, and HEC-1A cells transfected with MONC. MONC overexpression promotes expression of GLCE at the protein level. Simultaneously, transfection with AgomiR-636 rescued MONC from promoting GLCE protein expression (Fig. 4C).

To explore the effect of GLCE on the malignant biological behavior of ECSCs, we first transfected ECSCs, Ishikawa cells, and HEC-1A cells with GLCE overexpression plasmids, GLCE knockdown plasmids, and corresponding negative controls. The transfection efficiency was verified using qRT-PCR. A plasmid with the best knockdown effect (GLCE-RNAi(5952-1)) was selected for subsequent experiments (Figure S1B). Next, we performed a CCK-8 cell proliferation experiment and found that the proliferation rate in the GLCE-overexpressed group decreased, while the proliferation rate in the GLCE-knockdown group increased (Fig. 5A). The sphere formation assay indicated that the growth rate of ECSC spheroids in the GLCE overexpression group slowed down, while that in the GLCE knockdown group accelerated (Fig. 5B). We observed that the overexpression of GLCE inhibited the invasion of ECSCs, Ishikawa cells, and HEC-1A cells. Conversely, knockdown of GLCE promoted the invasion of ECSCs, Ishikawa cells, and HEC-1A cells (Fig. 5C). Next, we used flow cytometry to examine the effects of GLCE knockdown and overexpression on the cell cycle and apoptosis of ECSCs, Ishikawa cells, and HEC-1A cells. The results showed that overexpression of GLCE can induce cell cycle arrest at the G0/G1 phase, while knockdown of GLCE exerts the opposite effect (Fig. 5D). Overexpression of GLCE promotes apoptosis, and GLCE knockdown inhibits apoptosis (Fig. 5E).

Therefore, we speculated that GLCE expression is low in EC as a tumor suppressor gene and participates in the malignant progression of ECSCs and ECCs induced by MONC-miR-636. Among them, MONC can regulate miR-636 as the ceRNA of GLCE.

## Overexpression of MONC inhibits the Notch signaling pathway and inhibits the EMT process in ECSCs and ECCs, while miR-636 rescues the inhibitory effect of MONC overexpression

In order to explore the molecular mechanism of the downstream signaling pathway regulated by MONC and miR-636, we first constructed ECSCs, and Ishikawa and HEC-1A cell lines stably overexpressing MONC. AgomiR-636 was transfected into ECSCs, Ishikawa cells, and HEC-1A cells stably overexpressing MONC. We divided the experiment into three groups, namely, Control, MONC(+), and MONC(+) + miR-636(+). The protein levels of EMT-related indicators were detected using western blot. The results showed that MONC overexpression inhibited the expression of Snail1, Vimentin, and N-cadherin, and promoted the expression of E-cadherin. miR-636 can rescue the inhibitory effects of MONC overexpression on EMT process (Fig. 6A).

Therefore, we speculate that the knockdown of MONC overexpression in combination with miR-636 inhibits the EMT process in ECSCs and ECCs.

## Overexpression of MONC inhibited the growth of EC tumors in nude mice. miR-636 rescued the inhibitory effect of MONC overexpression on the growth of EC tumors.

We conducted nude mice tumorigenesis experiments to investigate the effect of MONC combined with miR-636 on tumor growth in nude mice. MONC(+) and MONC(+) + miR-636(+) ECSCs, Ishikawa cells, and HEC-1A cells were injected subcutaneously into nude mice.

The results are shown in Fig. 7. In the MONC(+) group and the MONC(+) + miR-636(+) group, the tumor volume and weight are smaller than that of the control group, and the MONC(+) group exhibits the smallest tumor volume (Fig. 7A). Further, we detected the expression of GLCE in the tumor using western blot. The expression of GLCE in the tumors of the MONC(+) group and the MONC(+) + miR-636(+) group increased, while GLCE expression is highest in the MONC(+) group (Fig. 7B). Results indicate that MONC can inhibit the growth of EC tumors, and miR-636 rescued MONC from inhibiting the growth of EC tumors.

## Discussion

Endometrial carcinoma (EC) is one of the three major malignant tumors of the female reproductive system<sup>[1]</sup>. The risk factors are related to age, obesity, hypertension, excessive endometrial exposure to estrogen, diabetes, and hereditary nonpolyposis colorectal cancer. At present, the main treatment is still total hysterectomy with bilateral salpingo-oophorectomy, while radiation and chemotherapy can also play therapeutic roles<sup>[18]</sup>.

CSCs can promote tumor growth, recurrence, metastasis, and drug resistance<sup>[19]</sup>. The functional role of CSCs in the generation and recurrence of malignant tumors has two key characteristics: the self-renewal capacity of CSCs and the potential to differentiate into an infinite group of heterogeneous cancer cells<sup>[20]</sup>. Due to the plasticity of CSCs, Stationary CSCs may produce cycling CSCs, leading to cancer recurrence<sup>[21]</sup>. Studies have shown that PKA activation promotes CSC state in small cell lung cancer<sup>[22]</sup>. In colorectal cancer, CSC evades treatment-mediated DNA damage by changing cell cycle checkpoints, increasing DNA damage repair capabilities, and effectively removing reactive oxygen species<sup>[23]</sup>. In recent years, there have been reports of ECSCs, but there are few related studies. Studies have found selective and specific effects of metformin on the activity of ECSCs<sup>[24]</sup>. In another study, SPIONs were found to be highly efficient nanocarriers for nucleic acids. Loading miR-326 on these carriers inhibited the activation of the GPR91/STAT3/VEGF signaling pathway and significantly reduced ECSC activity<sup>[25]</sup>. Moreover, our group used serum-free suspension culture to isolate ECSCs from Ishikawa cells in previous research<sup>[7]</sup>. In this study, we used serum-free suspension culture to isolate ECSCs from Ishikawa cells for subsequent experiments.

The mechanism of action of LncRNA in different tumors is inconsistent, and includes changes in histone modification, regulation of classic stem cell-related signaling pathways (such as SOX2/KLF4), induction of EMT, and inhibition of miRNA function<sup>[26]</sup>. Abnormal expression of LncRNA plays a key role in self-renewal, effective transformation of CSCs, and tumor progression. For example, the well-known LncRNA HOTAIR is significantly up-regulated and promotes CSC properties in breast and colon CSCs<sup>[27,28]</sup>. LncRNA HAND2-AS1 promotes self-renewal of liver CSCs and drives liver cancer<sup>[29]</sup>. LncRNA DLX6-AS1 down-regulation may inhibit methylation of the CADM1 promoter and the inactivation of the STAT3 signaling pathway, and up-regulate CADM1 to suppress stem cell characteristics of liver CSCs<sup>[30]</sup>. In related research on EC, Linc-RNA-RoR acts as a "sponge", preventing microRNA-145 from mediating ECSC differentiation<sup>[31]</sup>.

LncRNA can show similar effects as tumor suppressor genes or oncogenes by affecting various cellular processes related to cancer, including cell growth, metastasis, differentiation, and stemness<sup>[32]</sup>. LncRNA can act as competitive endogenous RNA (ceRNA) or a natural microRNA sponge, communicate with each other, and regulate together through the combination of competition and shared microRNA<sup>[33]</sup>. For example, LncRNA HOTTIP facilitates the development of breast cancer by regulating the miR-148a-3p/WNT1 pathway<sup>[34]</sup>. LncRNA ZEB2-AS1, through the miR-574-3p/HMGA2 axis, promotes the proliferation, migration, and invasion of esophageal squamous cell carcinoma cells<sup>[35]</sup>. Previous research indicates that LncRNA PVT1 promotes malignant tumors of human ECCs through the negative regulation of miR-195-5p<sup>[36]</sup>, and LINC01016 promotes the malignant phenotype of ECCs by regulating the miR-302a-3p/miR-3130-3p/NFYA/SATB1 axis<sup>[37]</sup>. In this article, we found that LncRNA MONC is lowly expressed in EC. MONC up-regulation inhibits the growth rate of ECSC spheres, while inhibiting proliferation and invasion, promoting apoptosis, and inducing cell cycle arrest at the G0/G1 phase in ECSCs, Ishikawa cells, and HEC-1A cells. Next, we found that MONC and miR-636 were relatively co-localized in the cytoplasm of Ishikawa cells by double fluorescence in situ hybridization (D-FISH). In order to evaluate the function of MONC, we predicted the binding site between MONC and miR-636 using RNAhybrid and verified the binding site between them using dual luciferase reporter gene detection. In addition, miR-636 knockdown can mediate tumor suppression related to MONC overexpression in ECSCs. In order to further explore the regulatory mechanism of MONC, we found that GLCE, as a tumor suppressor gene, is lowly expressed in EC and is the target mRNA of miR-636. MONC up-regulation promoted GLCE protein expression, while miR-636 rescued the promotion effect of MONC up-regulation on GLCE. Functional experiments show that GLCE up-regulation inhibits the growth rate of ECSC spheres, while also inhibiting proliferation and invasion, promoting apoptosis, and inducing cell cycle arrest at the G0/ G1 phase in ECSCs, Ishikawa cells, and HEC-1A cells. We believe that the MONC/miR-636/GLCE axis plays a crucial role in sphere formation, proliferation, invasion, apoptosis, and induction of cell cycle arrest in ECSCs and ECCs. This information could provide future treatment options for EC.

Most tumors are affected by EMT, the process of obtaining mesenchymal features from epithelial cells, during tumor progression. It is generally believed that cancers derived from epithelia are determined by the EMT process [38]. In human malignant tumors, among the transcription factors involved in EMT, Snail plays a major inducing role, while Twist and Zeb1/2 are mainly involved in retaining the aggressive mesenchymal phenotype. Activation of EMT is related to the generation of CSCs, and a connection exists between EMT, stemness, and the metastatic initiation potential of tumor cells [39]. In this article, MONC overexpression inhibits the expression of Snail1, Vimentin, and N-cadherin, and promotes the expression of E-cadherin. miR-636 can rescue the inhibitory effect of MONC overexpression on EMT process. We speculate that in ECSCs, MONC combined with miR-636 inhibits tumor EMT process.

## Conclusion

Our study confirmed, for the first time, that MONC inhibits the malignant biological behavior of ECSCs and ECCs by directly inhibiting miR-636. In addition, miR-636 may indirectly reduce the expression of MONC. Down-regulation of miR-636 may promote the expression of GLCE by targeting the 3'-untranslated region (UTR) of the downstream gene GLCE, thereby inhibiting the progression of ECSCs and ECCs. MONC combined with miR-636 inhibited the tumor EMT process. We believe that the MONC/miR-636/GLCE axis may provide a new therapeutic strategy for the treatment of human EC.

## Abbreviations

ECSCs: endometrial cancer stem cells

ECCs: endometrial cancer cells

EC: endometrial carcinoma

UTR: untranslated region

EMT: epithelial-to-mesenchymal transition

CSCs: Cancer stem cells

LncRNA: Long non-coding RNA

miRNA: MicroRNA

FBS: fetal bovine serum

PMSF: phenylmethanesulfonyl fluoride

ANOVA: one-way analysis of variance

qRT-PCR: quantitative real-time polymerase chain reaction

ceRNA: competitive endogenous RNA

## Declarations

## Acknowledgements

Not applicable.

## Authors' contributions

YL and XM designed the study. YL drafted the manuscript. JH and JH performed cell culture. All authors participated in manuscript editing. All authors read and approved the final manuscript.

## Funding

Our study was supported by the National Natural Science Foundation of China (No. 81872123), Liaoning Provincial Higher Education Innovation Team, Distinguished Professor of Liaoning Province, China Medical University's 2018 Discipline Construction "Major Special Construction Plan" (No. 3110118029), and Outstanding Scientific Fund of Shengjing Hospital (No. 201601).

## Availability of data and materials

All data generated or analyzed during this study are included in this published article.

# Ethics approval and consent to participate

This study was approved by the Institutional Review Committee (Ethical No. 2018PS251K/2018PS136K) of the Shengjing Hospital affiliated to China Medical University, and experimentation was conducted based on the approved guidelines.

## Consent for publication

Not applicable.

## Competing interests

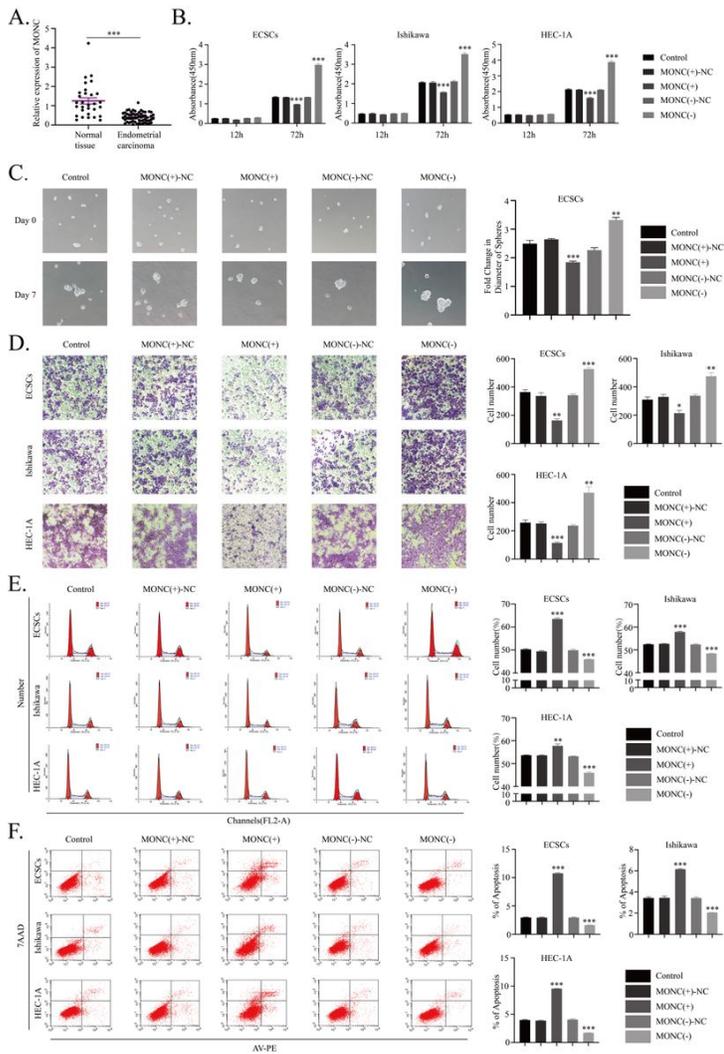

The authors declare that they have no competing interests.

## Figures

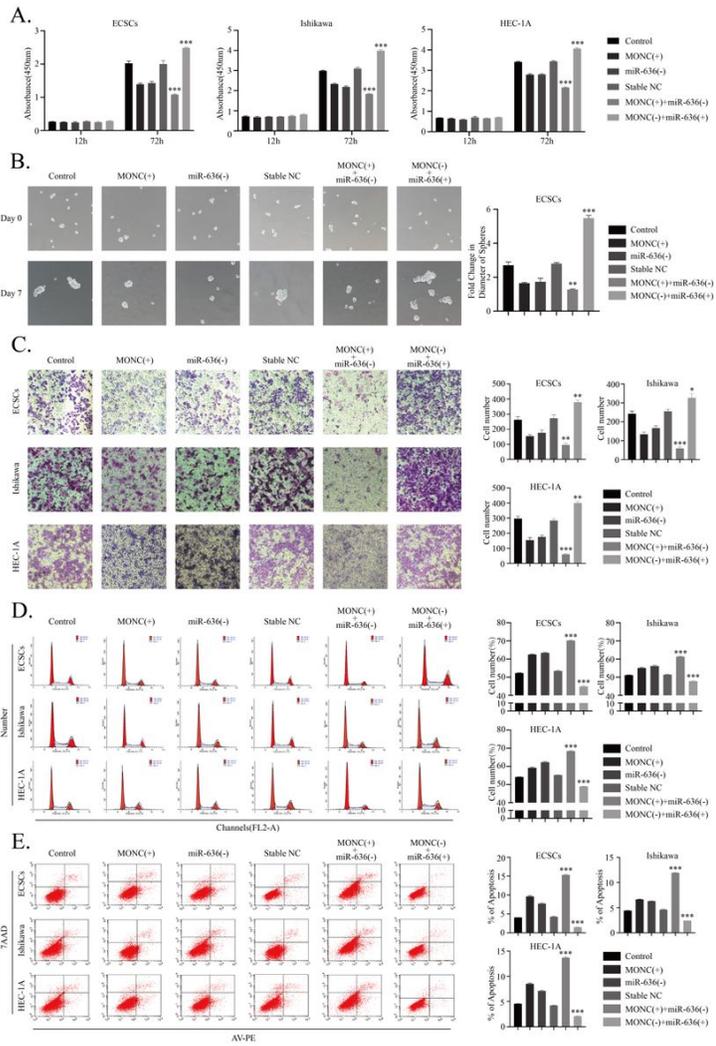

**Figure 1**

MONC is low expression in endometrial carcinoma and inhibits the malignant biological behavior of ECSCs and ECCs. A. qRT-PCR showed the expression of MONC in normal endometrial tissue (n = 30) and human endometrial carcinoma tissue (n = 60). B. CCK-8 was used to determine the effect of MONC on the proliferation of ECSCs, and Ishikawa and HEC-1A cell lines. C. The sphere formation assay was used to measure the effect of MONC on stem cell sphere formation. D. The Transwell invasion assay was used to determine the effect of MONC on the invasion ability of ECSCs, and Ishikawa and HEC-1A cell lines. E. Cell cycle analysis was used to detect the effect of MONC on the cell cycle of ECSCs, and Ishikawa and HEC-1A cell lines. F. Cell apoptosis assay was used to analyze the effect of MONC on apoptosis of ECSCs, and Ishikawa and HEC-1A cell lines. The data are expressed as mean  $\pm$  SEM (n = 3, each group). \* P <0.05, \*\* P <0.01, and \*\*\* P <0.001.

**Figure 2**

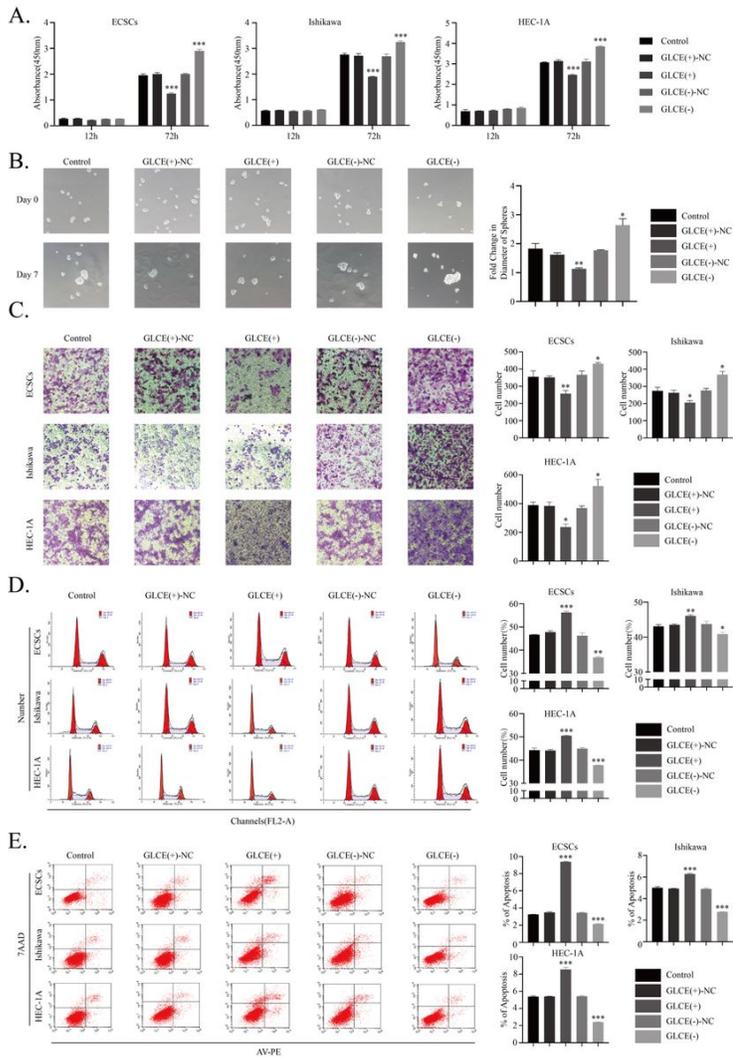

miR-636 is highly expressed in endometrial carcinoma, and MONC is the target of miR-636. A. qRT-PCR showed the expression of miR-636 in normal endometrial tissue (n = 30) and human endometrial carcinoma tissue (n = 60). B. Pearson's test analyzes the correlation between MONC and miR-636. C. qRT-PCR was used to detect the relative expression of miR-636 after overexpression and knockdown of MONC. D. qRT-PCR was used to detect the relative expression of MONC after overexpression and knockdown of miR-636. E. MONC and miR-636 were colocalized in Ishikawa cell by FISH. MONC was stained green, miR-636 was stained red, and nuclei were stained blue (DAPI). F. MONC (MONC-WT) predicted miR-636 binding site and the designed mutant sequence (MONC-Mut). Cells were transfected with MONC-WT or MONC-Mut and the indicated miR-636, and subjected to dual luciferase reporter gene analysis. The data are expressed as mean  $\pm$  SEM (n = 3, each group). \* P < 0.05, \*\* P < 0.01, and \*\*\* P < 0.001.

**Figure 3**

Knockdown of miR-636 mediates tumor suppressive effects of MONC overexpression in ECSCs, and ECCs. A. CCK-8 was used to determine the effects of MONC and miR-636 on the proliferation of ECSCs, and Ishikawa and HEC-1A cell lines. B. The sphere formation assay was used to determine the effect of MONC and miR-636 on stem cell sphere formation. C. The Transwell invasion assay was used to determine the effect of MONC and miR-636 on the invasion ability of ECSCs, and Ishikawa and HEC-1A cell lines. D. Cell cycle analysis was used to determine the effects of MONC and miR-636 on the cell cycle of ECSCs, and Ishikawa and HEC-1A cell lines. E. Cell apoptosis assay was used to analyze the effects of MONC and miR-636 on the apoptosis of ECSCs, and Ishikawa and HEC-1A cell lines. The data are expressed as mean  $\pm$  SEM (n = 3, each group). \* P < 0.05, \*\* P < 0.01, and \*\*\* P < 0.001.

**Figure 5**

GLCE inhibits the malignant biological behavior of ECSCs, and ECCs. A. CCK-8 was used to observe the effect of GLCE on the proliferation of ECSCs, and Ishikawa and HEC-1A cell lines. B. The sphere formation assay was used to determine the effect of GLCE on stem cell sphere formation. C. The Transwell invasion assay was used to determine the effect of GLCE on the invasion ability of ECSCs, and Ishikawa and HEC-1A cell lines. D. Cell cycle analysis was used to detect the effect of GLCE on the cell cycle of ECSCs, and Ishikawa and HEC-1A cell lines. E. Cell apoptosis assay was used to analyze the effect of GLCE on apoptosis of ECSCs, and Ishikawa and HEC-1A cell lines. The data are expressed as mean  $\pm$  SEM (n = 3, each group). \* P < 0.05, \*\* P < 0.01, and \*\*\* P < 0.001.
