Abstract

In India, sandstone was broadly used to construct structures like Agra fort, Red Fort Delhi and Allahabad fort, etc. Around the world, many historical structures were collapsed due to the adverse effect of damages. Structural health monitoring (SHM) is very useful to take appropriate action against the failure of structure. The Electro-mechanical impedance (EMI) technique is used to continuously monitor the damage. This technique is helped to analyse the hairline crack, location, and severity of damage to structural elements. A 10cm length and 5cm diameter sandstone cylinder was used in experimental work. A cutter was used to create the artificial damages of 2mm, 3mm, 4mm, and 5mm respectively along the length, at the same place in specimens. The signature was measured for each depth of damage between 30 kHz to 400 kHz frequency range. The comparative result of healthy and damages state with different depth was concluded base on EMI signature form the sample. RMSD Statistical methods like root mean square deviation (RMSD) is used for quantification of damage. This paper motivates the application of the EMI technique to the historical building made of sand stone as key material.

Keywords Structural health monitoring, EMI technique, Sensor system, Sandstone, Historical structure.

Introduction

A lot of historical structures exist on the earth which contains the importance of history, civilization, symbols, etc. The historical structure contains comprehensive valuable history (Berrocal-olave et al., 2021). From ancient times, marble, sandstone, granite, wood, iron, limestone was used as construction material (Spectus, 2010). In India, there are a huge amount of ancient and historical structures (Dighe et al., 2020). The historical structure contains different construction materials, designs, and aesthetic, which is related to cultural diversity and religious diversity in India (Prakash & Rajdeo, 2019) (Pinna et al., 2022).

Many structures and forts containing Art, culture, and religious value were constructed during the period of the Mughal Empire. During this period, marble, and sandstone were widely used as construction material. Taj Mahal is an example of white marble, and Agra and Delhi fort are examples of various types of sandstone construction material. 'Khusro Bagh' was also constructed by sandstone, lime mortar etc. The 'Khusro Bagh' is a large walled garden complex located close to the Prayagraj Junction railway station, in Prayagraj district, Uttar Pradesh, India (Prasad et al., 2019). The four sandstone mausoleums within this walled garden, present an exquisite example of Mughal architecture. The structures are respectively tombs of Prince Khusro, tombs of Shah Begum, Khusrau's sister, Nithar, and tombs of Bibi Tamolan Khusrau's tomb was completed in 1622, while that of Nithar Begum's, which lies between Shah Begum's and Khusrau's tombs, was built on her instructions in 1624-25. Most of the structures in the Khusro Bagh are constructed with sandstone masonry (Figure 1 (a)). Red, brown, yellow, and white colour sandstone with lime mortar have been used in Khusro Bagh structures. Primarily large amount of red sandstone is used in these structures.

Sandstone is a natural sedimentary rock. It is available in a vast amount on the earth. Sandstone has been a prevalent construction material from ancient times to till now. The compressive strength

91 and load-carrying capacity were high for sandstone
92 as compared to other ancient construction
93 materials. The sandstone has been used in beams,
94 columns, domes, Mihrab arch, flooring, wall,
95 fountains, etc., in structure. Sandstone is a hard
96 rock that contains sand-size grains of mineral,
97 sand, cementitious material, and organic material.
98 The formation of sandstone is in two phases. In the
99 first phase, sand particles sedimentation occurs
100 through air or water; in the second phase, the
101 compaction occurs with physical pressure and
102 chemical changes. Variable colours are found in
103 sandstone like red, black, brown, cream, dark-
104 brown, yellow, pink, white, light and dark grey,
105 etc. The colours of sandstone depend upon the
106 mineral composition. These days' sandstone is
107 broadly used in flooring, wall tiles, retaining wall,
108 river training and stone masonry, etc. No painting
109 is required after the use of sandstone. Sandstone
110 has a fabulous construction material due to its
111 shining, colour, and softness. The sandstone has
112 been widely used in new construction structures i.e.
113 Ambedkar Park Lucknow, Kashi Vishwanath
114 corridor Varanasi, etc.

115 Archaeological structures and heritage sites
116 located in India are exposed to the risks of
117 environmental (Ural & Dog, 2008; Saba et al.,
118 2018). Preserving cultural and architectural values
119 and stability is very important. Many types of
120 damage or deterioration occur in stone for various
121 reasons in historic structures (Mahesh et al., 2021;
122 Silva et al., 2022). The physical and chemical
123 environmental, and loading impacts are significant
124 causes of the deterioration of sandstone (Fermo et
125 al., 2015). Different types of pollution threaten the
126 existence of these historical structures and pieces of
127 evidence (Varotsos et al., 2009). Pollution is a
128 significant cause of the deterioration of historical
129 structures like the white colour of the Taj Mahal
130 marble has been going to yellowish colour due to
131 the acid rain (Natarajan, 2022). Within two decades,
132 the pollution is gradually rising due to the increasing
133 size of vehicles, factories, workshops, thermal
134 plants, refineries, and residential complexes
135 (Belfiore et al., 2013). CO (Carbon monoxide) and
136 SO₂ (Sulphur dioxide), are significant causes of
137 deterioration of the sandstone in Gwalior Fort
138 Madhya Pradesh (Pandey & Kumar, 2015). Rising
139 damp in structural components and air pollution
140 accelerates the deterioration of sandstone under the
141 presence of NO₂ and SO₂ (Batista et al., 2019). Joerg
142 Ruedrich et al. investigated the deterioration in
143 sandstone under the weather conditions like wet-dry.
144 They found the critical parameter is to increase the
145 porosity in the sandstone indicator of deterioration
146 (Ruedrich & Bartelsen, 2011). Akoğlu et al.
147 investigated the swelling which play's important
148 role for deterioration of sandstone under chloride
149 environment. The micro crack increased the
150 separation of layer especially along the bending

151 plan, affect the deterioration in sandstone (Saltik,
152 2010). Rina (Irena) Wasserman was investigated the
153 reason for sandstone deterioration was humidity,
154 saltwater and high air pollution (Wasserman, 2021).
155 Małgorzata Labus was investigated the deterioration
156 and weight loss in sandstone under insolation, rain
157 and frost (Labus and Bochen, 2012). J.J. Ortega-
158 Calve et al. were investigated some bacteria is
159 harmful to sandstone structure like cyanobacteria
160 and chlorophytes that are present near the soil,
161 plants, and surface of the structure (Ortega-calve
162 and Ariiio, 1995). The leading causes of the
163 deterioration in the historical building materials are
164 air pollution, temperature, acid rain, salt water, and
165 biological factor (Effectiveness et al., 2018)
166 (Vidović et al., 2022).

167 Structural health monitoring (SHM) has been
168 playing an important in preventing the abrupt failure
169 of structures such as towers, bridges, dams, offshore
170 structures, and buildings (Ai et al., 2014; Mishra,
171 2021). SHM techniques provide safety, reliability,
172 of structure. SHM is one of the best effective
173 industrialized methods for determining structural
174 integrity. SHM techniques is helpful for recognize
175 quality of structure, minor to major structural failure
176 with an early indication of damage. Measuring the
177 indication of the damage at an early stage through
178 the SHM technique is to take appropriate action to
179 prevent the damage before the collapse. It is a
180 process to determine the presence, location, severity
181 of damages present in the system, and also the
182 remaining service life of the system. In SHM,
183 various techniques are used to continuous or
184 discontinuous monitoring and study the change in
185 the behavior at any stage of the structure (Martínez-
186 garrido and Ergenc, 2016). SHM is divided into two
187 groups first is the global response technique, and the
188 second is the local technique. In global technique
189 contain static response and dynamic response
190 technique. The global dynamic response technique
191 is based on low frequency excitation and their
192 vibration response like displacement, velocity, and
193 acceleration, however global static response
194 technique is based on only static displacement
195 response. Mostly non-destructive evaluation (NDE)
196 test is conducted to evaluate the change in the
197 structural parameters. The local damage in structural
198 members plays a hostile role in the structure. Many
199 non-distractive tests, such as Ultrasonic, X-rays,
200 Eddy current, Magnetic particle, Dye penetrant,
201 EMI technique, etc., are conducted to evaluate the
202 performance of damages in members of the structure
203 (Maurya et al., 2020). The limitation of these
204 techniques is less sensing range, and most of the
205 method depends on the geometry, material
206 properties, and depth of cracks, etc. The minimum
207 and maximum probability sensitive range of the
208 local technique are provided in table 1.

209 The EMI technique is comparatively new in SHM.
210 Last few decades, this technique has been used in

211 buildings, bridges, railways, towers, etc., for
 212 monitoring purposes. EMI technology based on the
 213 piezoelectric ceramic (PZT) sensor has versatile
 214 potential applications in SHM (Dongyu et al., 2014;
 215 Bhalla & Soh, 2004a). The PZT sensors were used
 216 as embedded or surface-bonded inside the host
 217 specimens (Maurya et al., 2022a). The surface-
 218 bonded sensor applied at the surface with the help of
 219 high epoxy adhesive (Moharana & Bhalla, 2014;
 220 Saravanan & Chauhan, 2022). The embedded sensor
 221 is used inner part of the host structure (Negi et al.,
 222 2018). The PZT sensor effectively monitors and
 223 detects incipient damage (Shanker et al., 2011). The

224 incipient damage influences the strength and
 225 sustainability of structural members. This technique
 226 helps determine the incipient damage of structural
 227 elements. The PZTs sensor are also used in global
 228 dynamic response technique below the frequency
 229 range 100 Hz. The use of the EMI technique in
 230 aerospace and automobile sectors indicates the
 231 change in function during the operational process
 232 and any chance of malfunction. The PZT sensor is
 233 also used in parallel and series combination (Priya et
 234 al., 2018).

Table 1 Sensitivity range of common local techniques (Bhalla 2004)

S.	Name of Local Technique	Minimum probability detectable crack length	Maximum probability Detectable crack length (>95%)	Remarks
1	Ultrasonic pulse velocity	2mm	5-6mm	Depends upon the properties and geometry of material
2	X – Ray	4mm	10mm	Dependent upon Structural Member configuration. Better for thickness of member is grater then 12mm
3	Magnetic particle	2mm	4mm surface	--
4	Dye penetrant	2mm	10mm surface	--
5	Eddy currents (At low frequency)	2mm	4.5-8mm	Thickness of testing specimen <12mm only
6	Eddy currents (At high frequency)	2mm for surface and 0.5mm for bore holes	2.5 mm for surface and 1.0mm for bore holes	--

240

241 **Environmental impact on historical**
242 **structure**

243 Environmental impact on sandstone structure is a
244 lengthy and time taken process. Acid water,
245 temperature, pressure, wet-dry, humidity, freeze-
246 thaw, etc., are significant causes of deterioration
247 of historical structures under the environmental
248 impact (Batista et al., 2019; Manohar et al.,
249 2020). The porosity participates in the
250 deterioration of stone due to environmental
251 effects. The variation of temperature with sudden
252 rainwater is very harmful to structure.
253 The shrinkage and swelling is a major process of
254 deterioration of historical stone structure. The
255 porosity of stone rock plays a vital role in
256 durability. The deterioration rate of stone
257 depends upon the porosity; damage or
258 deterioration rises gradually when porosity
259 increases. Figure 2 (a), (b), (c), and (d) contain
260 the deterioration of sandstone in the Khusro
261 tombs structure.
262

263 **Loading impact on historical structure**

264
265 The loading impact on historical structure cause
266 by dead load, live load, earthquake load, wind
267 load, vibration loads. Generally, no new
268 construction occurs on historical structure due to
269 no change in historical originality, so the dead
270 load does not increase. Mostly the vibration load
271 and earthquake loads are very harmful as
272 compared to other loads. Now a day development
273 is a need of every city. The rate of growth of the
274 infrastructure of the city is very high. The need
275 of human being in the city is the metro, multi-
276 story building, water tank, water supply line,
277 electricity and mobile tower, and railway line and
314

278 station. New construction near the historical site
279 produces vibration due to transport systems,
280 electrification, water supply line, tower, bridges,
281 metro, railway etc. The heavy vibration
282 equipment in the construction industry produces
283 vibration, which harms the stability of the
284 historic structure.

285
286

287 **Materials and Methods**

288

289 **Experimental work**

290

291 The PZT-5H square sensor of 1×1 cm is
292 manufactured by Ceramic India Ltd. The
293 properties of the PZT-5H sensor are given in
294 table 2. This PZT sensor has contained both
295 nodes on the upper surface. A special type of low
296 resistance single core wire of one meter was
297 attached to PZT nodes. A smooth surface
298 sandstone specimen of 10 cm in length and 5cm
299 in diameter have been used for testing collected
300 from the Khusro tomb. The center of specimen
301 diameter is also the center of PZT patch. The
302 high-strength epoxy has been used to attach the
303 PZT sensor to the sandstone surface. A LCR
304 meter is used to measure the signature
305 conductance and susceptance. One end of the
306 wire attached with PZT electrode and another
307 end of this wire is connected with an LCR meter.
308 To analyze the sustainability of sandstone, the
309 manual damage has been created along the length
310 at depths of 2mm, 3mm, 4mm, and 5mm
311 respectively, at the same place in specimens with
312 the help of a cutter. Figure 3 is the experimental
313 test setup for testing in the laboratory.

321 Properties of sandstone

322

323 The sandstone is a sedimentary rock that forms
324 by clastic sedimentation of sand, minerals,
325 organic compounds, cementitious, matrix
326 material. The size of grains of minerals ranges
327 from 0.06 to 2 mm and wide range of the strength
328 from less than 5.0 MPa to over 150 MPa. The
329 strength is depending upon the porosity,
330 cementitious material, matrix material, grain size,
331 composition. In this experimental the sandstone
332 sample made by the collected sandstone from
333 tombs of Prince Khusro in figure 1 (a), (b), and
334 (c). A lithological characteristics studies of
335 sandstone sample have been conducted. The
336 sample is characterized by non-bedded structure;
337 it is compacted in nature. It is containing Quartz
338 and orthoclase. The rock has clastic texture.
339 Subordinate amount of muscovite mineral is
340 present

361

341

342 Damage in sandstone

343

344 The volumetric change in the original objects is
345 called deterioration/damage. There are many
346 causes of damage in sandstone like
347 environmental and loading impact (Korkanç,
348 2013). The environmental deterioration is
349 gradual deterioration. Small pieces erosion of
350 sandstone are spall out from in the structure
351 when the surface deterioration starts in
352 sandstone. The depth of damage increases when
353 the material spalls out from the structure. In this
354 experimental work the depth of damage is
355 gradually increase up to 5mm depth. A cutter
356 used to create the artificial damages in the
357 specimen along the length. The damage depth is
358 2mm, 3mm, 4mm, and 5mm. The signature has
359 been measured at every depth of damage (figure
360 4 (a), (b), (c), and (d)).

362

363

364

Fig. 4 (a), (b), (c) and (d) are 2mm, 3mm, 4mm, and 5mm depth of damage respectively.

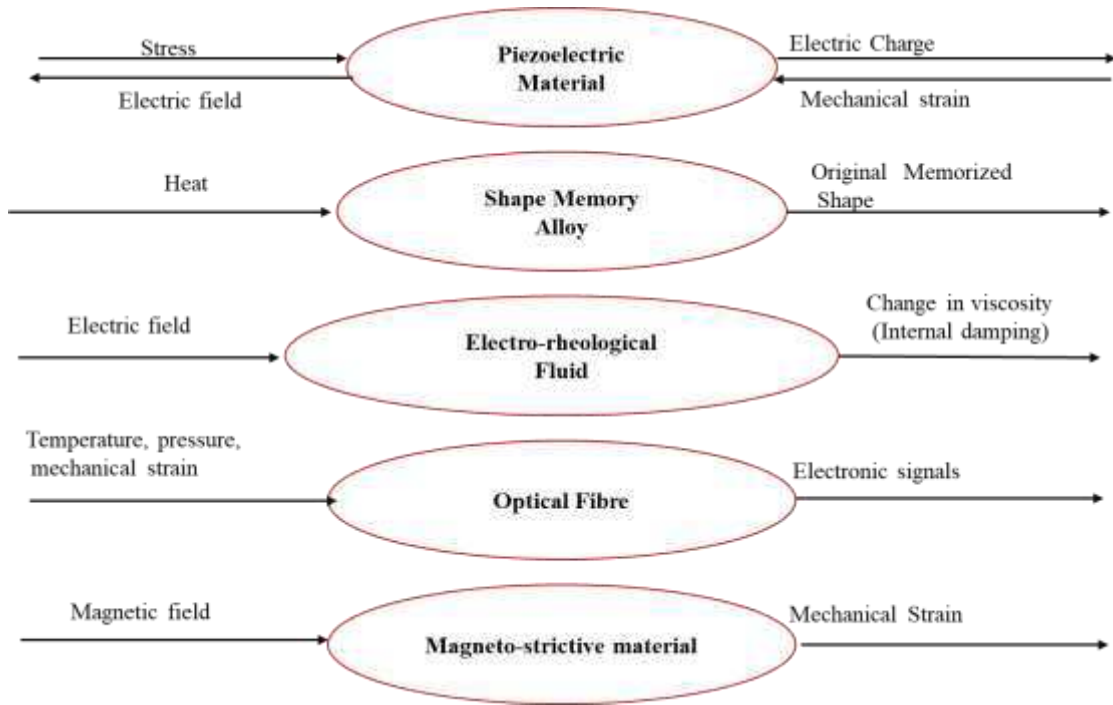

Fig. 5 Common smart materials: applications and the associated stimulus-response.

365
366

368
369 **Piezoelectric materials**

370
371 Some unique crystal materials like PZT [Pb (Zr1-
372 xTix) O₃], PLZT [(Pb1-xLax) (Zr1-yTiy) O₃],
373 lithium Niobate (LiNbO₃), and quartz (SiO₂),
374 etc., have the piezoelectric effect. These types of
375 crystal is also called non-centrosymmetric
376 crystals. The chemical composition of piezo-
377 ceramic is [Pb (Zr1-xTix) O₃]. Generally, the
378 piezo-ceramic is called PZT. PZT has an
379 interesting smartness when the voltage applied
380 on PZT it generates mechanical force and, when
381 it is subjected to mechanical force, becomes
382 electrically polarized. PZT is a smart material
383 that have dual character, sensor as well as an
384 actuator (Shanker et al., 2011). Various types of
385 PZTs patches are commercially available such as
386 specification, sensing frequency range, and
387 shapes. Figure 6 is an experimental PZT patch
388 having a size of 1cm×1cm.

389
$$D_i = \epsilon_{ij}^T E_j + d_{im}^d T_m \quad 1$$

390
$$S_k = d_{jk}^c E_j + s_{km}^E T_m \quad 2$$

391 Where equation 1 is direct effect and
392 equation 2 is converse effect. The equations 1
393 and 2 can be rewritten in the tensor form as
394 equation 3 (Sirohi & Chopra, 2000).

395
$$\begin{bmatrix} D \\ S \end{bmatrix} = \begin{bmatrix} \epsilon^T & d^d \\ d^c & s^E \end{bmatrix} \begin{bmatrix} E \\ T \end{bmatrix} \quad 3$$

396 Where (D) is the electric displacement vector
397 quantity [3x1] and unit is (C/m²), (S) is the
398 second order strain tensor [3x3], (E) is applied
399 external electric field vector [3x1] and unit is

400 (V/m). T is stress tensor [3x3] and unit is (N/m²).
401 (ϵ) is di-electric permittivity. (ϵ^T) is the second
402 order dielectric permittivity tensor under constant
403 stress and unit is (F/m), (dd) and (dc) is the third
404 order piezoelectric strain coefficient tensors and
405 unit is respectively (C/N), (m/V). (s^E) is fourth
406 order elastic compliance tensor under constant
407 electric field and unit is (m²/N).

Dielectric loss factor	δ	-	0.02
Poisson's	μ	-	0.31

413

414

415 EMI technique

416

417 EMI technique is NDE method. In the EMI
 418 technique, a PZT patch is used to monitor the
 419 health of the structure within a specific range of
 420 frequency. The EMI technique is similar to the
 421 global dynamic response techniques. In the
 422 global dynamic response technique, the
 423 frequency range works less than 100 Hz. Within
 424 100Hz frequency is not suitable for incipient and
 425 hairline damage (Maurya et al., 2022b). The
 426 incipient and hairline damage evaluation and
 427 repair are necessary to prevent the big failure.
 428 The EMI technique is helpful to the measure the
 429 incipient damage, severity, and location of
 430 damages. The difference between in global
 431 dynamic technique and EMI is the frequency
 432 range. EMI technique works on 30 kHz-400 kHz
 433 frequency range. An LCR meter or impedance
 434 analyzer is used to acquire the signature. The
 435 LCR meter measures the admittance which
 436 consists of the real part (conductance) and
 437 imaginary part (susceptance), when plotted as a
 438 function of frequency, gives a unique signature to
 439 structures. 1-D and 2-D expressions of
 440 electromechanical admittance, written below in
 441 equations 4 and 5 respectively. (Consumption,
 442 1994; Bhalla & Soh, 2004a, 2004b).

$$443 \quad \bar{Y} = G + Bj = 2\omega j \frac{wl}{h} \left[\left(\epsilon_{33}^T - d_{31}^2 \bar{Y}^E \right) + \right. \\ 444 \quad \left. \left(\frac{Z_a}{Z + Z_a} \right) d_{31}^2 \bar{Y}^E \left(\frac{\tan kl}{kl} \right) \right] \quad 4$$

$$445 \quad \bar{Y} = G + Bj = 4\omega j \frac{l^2}{h} \left[\left(\frac{\bar{\epsilon}_{33}^T}{\epsilon_{33}^T} - \frac{d_{31}^2 \bar{Y}^E}{1-\nu} \right) + \right.$$

$$446 \quad \left. \left(\frac{Z_{a,eff}}{Z_{s,eff} + Z_{a,eff}} \right) \frac{d_{31}^2 \bar{Y}^E}{1-\nu} \bar{T} \right] \quad 5$$

447 Where \bar{Y} is complex electromechanical
 448 admittance, G is conductance, B is susceptance,
 449 Z is mechanical impedance, Z_a is mechanical
 450 impedance of the PZT patch, d is piezoelectric
 451 strain coefficient, ω is angular velocity, l is half-
 452 length of PZT patch, h is thickness of PZT patch,
 453 w is width of PZT patch,, ϵ is electric
 454 permittivity, $\bar{\epsilon}_{33}^T$ is complex electric permittivity
 455 at constant stress, \bar{Y}^E is complex Young's
 456 modulus of elasticity at constant electric field, k
 457 is spring constant, ν is Poisson's ratio, \bar{T} is
 458 complex tangent function, Z_{a,eff} is effective
 459 impedance of the PZT patch, Z_{s,eff} is effective
 460 impedance of the structure, $j = \sqrt{-1}$.

461

462 Major findings

463

464 The variation of conductance has been
 465 measured, such as the conductance signature of
 466 health state and at damage depths of 2mm, 3mm,
 467 4mm, and 5mm, respectively. All conductance
 468 signatures are shown compared with healthy state
 469 conductance signatures in Figures 7, 9, 11, 13,
 470 and 15.

471 The susceptance signature is imaginary part
 472 of the admittance. The variation of susceptance
 473 signature is very slight as compared to the
 474 conductance signature. The susceptance signature
 475 has been measured at a healthy state and various
 476 damage depths such as 2mm, 3mm, 4mm, and
 477 5mm, respectively, which are in figure 8, 10, 12,
 478 14, and 16.

479 A comparative signature of conductance at
 480 the healthy state with various depths of damage
 481 has been in Figure 17.

482 A comparative signature of susceptance at the
 483 healthy state with various depths of damage has
 484 been in Figure 18.

485 Shifting the signature curve towards the left
 486 side from the baseline indicates the damage in
 487 the specimen. The shifting of curves was directly
 488 dependent upon the depth of damage when the
 489 depth of damage increases then the shifting
 490 towards the left side in conductance and
 491 susceptance signature. The change in the 5 mm
 492 damage signature is high compared to other
 493 signatures.

494 The percentage RMSD value is used for the
 495 evaluation of the damage. The percentage RMSD
 496 values was calculated for conductance and
 497 susceptance was shown in figure 19.

498 With the help of conductance and
 499 susceptance percentage, curve of RMSD value is
 500 plotted in figure 20.

537 Evaluation of conductance and
538 susceptance signature

539 The purpose of the evaluation is co-related with
540 structural functions like strength gain and
541 losses, damage, early strength change, etc.
542 There are serval statistical methods like RMSD,
543 mean absolute percentage deviation (MAPD),
544 covariance (Cov), and correlation coefficient
545 (CC) is used to evaluate the damage. The
546 RMSD value is calculated with the help of
547 conductance and susceptance signature. In the
548 EMI technique, the RMSD is widely used to
549 assess the damage's severity. The severity of
550 damage is estimated by the amount of variations
551 between two conductance and susceptance
552

553 signatures. The equitation of percentage RMSD
554 is written in equitation number 5.

$$555 \text{ RMSD (\%)} = \sqrt{\frac{\sum_{i=1}^N (G_i^1 - G_i^0)^2}{\sum_{i=1}^N (G_i^0)^2}} \times 100 \quad 5$$

556 The variation of conductance and susceptance
557 both are calculated individual. A significant
558 change was found in RMSD value of
559 conductance signatures compared to RMSD
560 values of susceptance signature. The RMSD
561 value of conductance and susceptance at
562 different depths of damage is shown in figure
563 19. The equitation of percentage RMSD is
564 shown in figure 20.

578 Results

579
580 A comparative result of conductance signature is
581 in figure 17. The continuous shifting has been
582 observed in conductance signature from baseline
583 up to 5 mm damage. The 2mm, 3mm, 4mm, and
584 5mm, has been observed a continuous increase in
585 damage then; the signature of conductance also
586 shift towards the left side. It indicates the severity
587 of the damage. The shifting depends upon the
588 damage level; if the damage is more than 5 mm,
589 then the curve may shift more on the left side.

590 The percentage of RMSD values also depends
591 on damage severity. A linear function generated
592 with the help of the percentage of RMSD values
593 has been correlated in the form of a straight line.
594 Generated linear function may be use damage
595 more than 5mm of depth.

597 Limitations

598
599 Most of the chance is PZT patch gets broken due
600 to its brittle nature when removed from the host
601 structure. The PZT patch sensing zone is limited.
602 The sensing range depends upon material shape,
603 size, and properties of the material. Generally is a
604 0.4 to 2 meters length of sensing zone. Aging,
605 mechanical, electrical, and thermal, etc., are
606 some limitations of the PZT patch. The main
607 restrictions in the historical structure are the
608 originality and aesthetic view of the structure.
609 The sandstone masonry structure contains
610 different bonding materials such as lime mortar,
611 etc. at this junction point, the signature is
612 affected.

614 Conclusions

615
616 The historical structure is very important in
617 culture, history, and tourism. Health monitoring
618 is necessary for preventing the adverse effect of
619 structure. The EMI technique is helpful to
620 determine the incipient damage as well as
621 damage severity for the sustainability of
622 historical structure made of sandstone.

623 There are lot of restrictions on the historical
624 structure that does not change its originality of
625 structure. Due to this limitation a non-destructive
626 test is useful for monitoring the health of
627 historical structure. This technique may be
628 directly used to monitor the health of structures
629 within the restriction of historic structures.

630 The baseline of the signature is very useful
631 for the future analysis of damage and
632 rehabilitation of the structure. The conductance
633 signature and susceptance signature are co-
634 related to the strength gain and losses of the
635 specimen.

636 The PZT size is tiny, so this technique does
637 not affect the aesthetic or harm the historical
638 structure. This technique is less time consuming.

639 The percentage RMSD value is used to
640 evaluate the damage and further deterioration in
641 the structure.
