Additional Declarations: Competing interest reported. RH, JR and JtM are inventors on a patent application relating to a M-cell targeted SARS-CoV-2 and H1-influenza virus vaccine. DH, NT, MMN, KDC, DC, AG, AB, JM, BJ, MG, and HH declare no conflict of interest.

Version of Record: A version of this preprint was published at Scientific Reports on March 21st, 2023. See the published version at <https://doi.org/10.1038/s41598-023-31198-3>.

Abstract

SARS-CoV-2 continues to circulate in the human population necessitating regular booster immunization for its long-term control. Ideally, vaccines should ideally not only protect against symptomatic disease, but also prevent transmission via asymptomatic shedding and cover existing and future variants of the virus. This may ultimately only be possible through induction of potent and long-lasting immune responses in the nasopharyngeal tract, the initial entry site of SARS-CoV-2. To this end, we have designed a vaccine based on recombinantly expressed receptor binding domain (RBD) of SARS-CoV-2, fused to the C-terminus of *C. perfringens* enterotoxin (cCPE), which is known to target Claudin-4, a matrix molecule highly expressed on mucosal microfold (M) cells of the nasal and bronchial-associated lymphoid tissues. To further enhance immune responses, the vaccine was adjuvanted with a novel toll-like receptor 3/RIG-I agonist (Riboxxim™), consisting of synthetic short double stranded RNA. Intranasal prime-boost immunization of mice induced robust mucosal and systemic anti-SARS-CoV-2 neutralizing antibody responses against SARS-CoV-2 strains Wuhan-Hu-1, and several variants (B.1.351/beta, B.1.1.7/alpha, B.1.617.2/delta), as well as systemic T-cell responses. A combination vaccine with M-cell targeted recombinant HA1 from an H1N1 G4 influenza strain also induced mucosal and systemic antibodies against influenza. Taken together, the data show that development of an intranasal SARS-CoV-2 vaccine based on recombinant RBD adjuvanted with a TLR3 agonist is feasible, also as a combination vaccine against influenza.

Introduction

Worldwide, SARS-CoV-2 infections have now surpassed 590 million and COVID-related deaths 6.44 million (WHO, August 2022). Several mRNA or adenoviral vector-based vaccines have received full or emergency authorization and are being rolled out in many countries. These vaccines have shown very high efficacy in protecting against hospitalization and death from Covid-19, and 67 to > 94% efficacy against infection in phase 3 clinical trials (*McDonald 2021*). However, since all but one recently approved inhalable vaccine are administered via intramuscular injection, they do not induce significant levels of mucosal antibodies in the nasopharyngeal tract, the site of initial viral replication which limits the impact of these vaccines on the spread of the virus in the community. Breakthrough infections with especially the delta variants of SARS-COV-2 (B.1.617.2 and AY.1 sub-lineages) were associated with high levels of viral replication in the respiratory tract and high transmission rates to both to vaccinated and unvaccinated persons (*Pouwels 2021, Eyre 2022*). Natural antibody-mediated protection for SARS-CoV-2 is likely to last for only 1–2 years and therefore, if vaccine-induced antibodies follow a similar course, regular booster doses will likely be required as long as the virus circulates in the human population (*Hamadi 2021, Goldberg 2022*). In observational studies of natural SARS-CoV-2 infection, higher levels of nasal antibodies directed against the RBD or spike protein were associated with a lower viral load, and the resolution of systemic symptoms (*Fröberg 2021*). To this end, efforts to develop nasal SARS-CoV-2 vaccines using different modalities, such as adenoviral vectors expressing recombinant spike protein, are currently underway and potentially attractive vaccine platforms to control the spread of COVID-19 in the

community (*Chavda 2021*). Importantly, any viable intranasal SARS-CoV-2 vaccine will be expected to generate protection against systemic disease at the same levels as the currently approved vaccines.

The RBD of the SARS-CoV-2 spike is an attractive vaccine antigen because most neutralizing antibodies cloned from human patients are directed against it, especially against epitopes involved in binding to the ACE2 receptor (*Min 2021*). Induction of mucosal immune responses requires transport of antigens across the epithelial barrier via specialized phagocytic cells called microfold cells (M-cells), and uptake and processing of antigens by resident macrophages and dendritic cells in the context of activating signals, such as pathogen associated molecular patterns (*Kanaya 2019*). In the airways, M-cells are found in the epithelium overlying the nasopharynx associated lymphoid tissues (NALT) and express claudins on their basolateral surface, which are ~ 23-kDa four- α -helical transmembrane proteins that assemble into “tight-junction strands” to seal the intercellular space. Targeting M-cells with polypeptides binding to claudin-4, such as the C-terminus of *Clostridium perfringens* enterotoxin (cCPE) fused to vaccine antigens has been shown to increase local and systemic immune responses against influenza, pneumococcus and other pathogens (*Lan 2019, Lo 2012, Suzuki 2018*). We therefore hypothesize that a targeting SARS-CoV-2 RBD to M-cells in the NALT will increase the immunogenicity of the vaccine.

Previous efforts to develop intranasal vaccines based on soluble recombinant proteins have demonstrated that without adjuvants neither sustained local nor systemic immune responses can be generated (*Holmgren 2005; Lycke 2012*). Toll-like receptor 3 (TLR3), which is activated by the double stranded RNA intermediates of respiratory RNA viruses, is a potentially attractive target for adjuvants because nasal epithelial cells express TLR3 (*Tengroth 2014*). TLR3 agonists have been used previously as safe adjuvants for intranasal immunization of human volunteers with trivalent influenza vaccine or as monotherapy post-exposure prophylaxis given up to 48h post challenge with influenza or rhinovirus (*Overton 2014, Malcolm 2018*). We used the novel synthetic double stranded RNA (dsRNA) adjuvant Riboxsim™, a TLR3/RIG-I ligand, characterized by its well-defined chemical structure with a nucleotide composition of 100 bp for effective TLR3 triggering and strong activation of human dendritic cells (*Naumann 2013, Koerner 2021*). Riboxsim exhibits very good solubility in water and prolonged stability in solution at 4°C and in serum.

The novel RBD-based intranasal vaccine presented here induced strong mucosal and systemic neutralizing antibody responses against SARS-CoV-2 Wuhan strain, as well as alpha, beta and delta variants, both when used for intranasal prime/intranasal boost as well as for subcutaneous prime/intranasal boost in mice. Robust CD4 and CD8 t-cell responses were induced as well. Lastly, the platform lends itself to adding additional antigens, such as influenza hemagglutinin (HA), which raises the prospect of developing combination vaccines against Covid and other respiratory infections.

Results

Recombinant SARS-CoV-2 receptor binding domain retains conformational epitopes and is stable at 4°C and – 80°C

Conformational stability of recombinant RBD or RBD-cCPE were assessed by ELISA using recombinant ACE2 protein, and the conformationally sensitive recombinant human anti-RBD monoclonal antibody CR3022 (ter Meulen, 2006). Purified recombinant RBD and RBD-cCPE were recognized by ACE2 and CR3022, with and without Riboxxim, and stable at 4°C and at -80°C for at least 2 months without loss of activity (Suppl. Figure 1).

SARS-CoV-2 RBD-cCPE vaccines induce RBD and spike binding IgA and IgG antibodies

Serum, NALF and BALF of mice were obtained seven days post-boost immunization (day 28 post prime) with different vaccine formulations (Table. 1). IgA and IgG antibodies binding to recombinant monomeric SARS-CoV-2 RBD or trimeric SARS-CoV-2 spike protein were determined using Luminex or ELISA, respectively, with no significant differences observed in antibody titers against the antigens. No specific antibodies were detectable in sera of mice from groups #4 (RBD, no Riboxxim), group #5 (Riboxxim only), group #6 (Riboxxim and Chitosan only), group #8 (RBD-cCPE), and group #9 (PBS control) (data not shown). Antibodies were detected in serum, NALF and BALF of all animals immunized with RBD plus Riboxxim (group #1, Fig. 1a, b, c), or RBD-cCPE plus Riboxxim (group #7, Fig. 1a, b, c), and also in all animals who were primed subcutaneously and boosted intranasally with RBD plus Riboxxim (group #2, Fig. 1a, b, c). Highest antibody titers were observed in animals immunized with RBD-cCPE adjuvanted with Riboxxim, followed by adjuvanted RBD. *Suppl. Figure 2a* shows the superior immunogenicity (seroconversion, GMT) of RBD-cCPE over RBD, which resulted in IgG-GMT that were 11.9-fold, 9.9-fold and 5.7-fold higher in serum, BALF, and NALF, respectively, compared to RBD. In a linear regression model, RBD-cCPE was the most important predictor ($p = 0.39$ for NALF, $p = 0.032$ for BALF, $p = 0.063$ for serum. *suppl. Figure 2a*). Variability of IgG titers was high in NALF for all vaccine groups (endpoint titer range 0-327680 Fig. 1a), in BALF for groups #1, #2 and #3 (Fig. 1b), and in serum for groups #1 and #2 (Fig. 1c). In contrast, variability was low between animals of group #7 in BALF and in serum (Fig. 1b and c), with highest titers observed in the latter. In serum, EC50 titers for group #7 were approx. $4E3$ (range 11059–36581), with EP titers exceeding $3E6$; in BALF EC50 titers for group #7 approached $3E3$, with EP titers exceeding $3E5$ (Fig. 1b and c).

IgA responses were only detected in groups #1 and #7, ranging from $3E1$ to $2E4$ in NALF and BALF (Fig. 2a and b), and from $3E3$ to $2E5$ in serum (Fig. 2c). In NALF, RBD-cCPE/Riboxxim induced 1.7-fold higher GMT titers compared to RBD, in BALF the GMT increase was 2-fold, and in serum the GMT increase was 3.7-fold (data not shown).

SARS-CoV-2 RBD-cCPE vaccine induces SARS pseudotype (Wuhan-Hu-1, VoC B1.1.7 and B1.351) neutralizing antibodies

Neutralizing antibody titers were determined in BALF, and sera collected on day 7 post-boost immunization (day 28 post prime) against lentiviral vectors pseudotyped with SARS-CoV-2 spike from

Wuhan-Hu-1 (wildtype), and variants B.1.1.7 (Alpha) and B.1.351 (Beta). No neutralization tests were performed on mice from groups #3–6 and #8, because they had no or only low binding antibodies. Neutralizing antibodies were detectable in all sera and two BALF (animals 7b + c) of mice belonging to groups #1 (RBD/Riboxxim), #2 (RBD-cCPE/Riboxxim, subcutaneous prime/intranasal boost), and #7 (RBD-cCPE), with most consistent response (100% seroconversion) and highest IC₅₀ titers observed in the mice which received RBD-cCPE together with Riboxxim (Fig. 3a-d and Fig. 4a,b). All sera with neutralizing antibodies neutralized WT and B.1.1.7 variant, with similar IC₅₀ titers, whereas IC₅₀ titers were approx. 10-fold lower for the B.1.351 variant (Fig. 4a-d). Figures 3a,b and 4a,b depict results of independent experiments. Neutralizing antibodies were also detected in BALF of 2/5 mice immunized with RBD-cCPE (Fig. 3e).

Bivalent SARS-CoV-2 RBD-cCPE / H1 Influenza HA₁-cCPE vaccine induces RBD, spike and HA1 binding, and SARS pseudotype neutralizing antibodies

NALF, BALF and serum of mice obtained on day 28 post prime immunization (day 7 post boost) with bivalent SARS-CoV-2/Influenza vaccine were assayed for IgG and IgA antibodies for binding to recombinant RBD (Wuhan-Hu-1/wildtype, or RBD point mutations N501Y, or E484K), or recombinant trimeric spike protein (WT, variants B.1.1.7/alpha and B.1.351/beta), or recombinant H1-HA₁ (consensus sequence based on H1N1/swine/Guangxi/3843/2011), using Luminex technology for IgG and ELISA for IgA, respectively. High IgG antibody titers with similar binding to SARS-CoV-2 RBDs (WT,point mutants), WT and mutated spike-trimers were detectable in NALF, BALF and serum, with EP titers in the 1E4 to 5E5 range (Fig. 5a-c). IgG antibodies against recombinant monomeric H1-HA₁ were detected in all three body fluids, with highest titers in NALF and BALF (Fig. 5a-c). Similarly, IgA antibody reactive with RBD and spike was detected in NALF, BALF and serum, with EP ranging from 1E4 to 1E6 (Fig. 6a-c). IgA antibodies specific for H1-HA₁ were detectable in NALF, BALF and serum, with EP titers ranging from 1E1 to 1E4 (Fig. 6a-c).

Neutralizing antibodies against WT Wuhan-Hu-1 SARS-CoV-2 PV were detectable in NALF (range 0-175), BALF (86-1141) and serum (1320->5120) serum of all animals (Fig. 7a-c) and against the variant B.1.617.2 (Delta) in 2/5 NALF, 3/5 BALF and in 4/5 sera with similar IC₅₀ titers as against the wildtype (Fig. 8a-c).

Monovalent SARS-CoV-2 RBD-cCPE and bivalent SARS-CoV-2 RBD-cCPE/H1 influenza HA1-cCPE vaccines induce strong CD4 and CD8 T-cell responses

In addition to the generation of neutralizing antibodies, the systemic T cell response against the SARS-CoV-2 RBD and influenza H1-HA1 was analyzed for monovalent and bivalent vaccine formulations. On day 28 post prime (7 days post boost), splenocytes were isolated and antigen specific T cell responses measured by IFN γ secretion in ELISPOT. For monovalent vaccines, strong IFN γ secretion in response to stimulation with RBD were detectable for both CD4⁺ and CD8⁺ T cells in all vaccinated groups, with highest number of spot forming units observed in mice from group #7, ranging for CD4⁺ and CD8⁺ T-cells

from 939–1034/1E6 and 233–670/1E6 splenocytes, respectively. While T-cell responses between groups #1 and #2 were not statistically significantly different, T-cell responses in group #7 (RBD-C-CPE) were significantly higher than those in groups #1 (RBD) and #2 (RBD, subcutaneous prime/intranasal boost, Fig. 9a,b). A bivalent SARS-CoV-2 RBD-cCPE / influenza H1-HA₁-cCPE vaccine adjuvanted with Riboxim induced similarly potent T cell responses against both the RBD and H1-HA₁,

Materials And Methods

Production Of Recombinant Sars-cov-2 Receptor Binding Domains, Influenza H1-ha Antigen, And Human Ace2

The SARS-CoV-2 Spike S1 (RBD) target sequence (AA 319–541) was synthesized as gBLOCK gene fragment (Integrated DNA Technologies, Inc) containing a C-terminal octa-histidine tag and cloned into expression vector pTZ_M_24 (trenzyme GmbH) containing an optimized secretion signal. The SARS-CoV-2 Spike S1 (RBD) - fusion protein containing AA 319–541 of SARS-CoV-2 Spike S1 (RBD) fused

at its C-terminus via a short linker sequence (GGGGS) to AA 194–319 of *Clostridium perfringens* heat-labile enterotoxin B chain (cCPE) was synthesized as described above and cloned into expression vector pTZ_M_26 (trenzyme GmbH) containing an optimized secretion signal followed by a nona-histidine tag. The hACE2 target sequence (AA 20–708) was synthesized as described and cloned into expression vector pTZ_M_27a containing an optimized N-terminal secretion signal and a C-terminal TEV-cleavable octa-histidine tag. Recombinant H1-HA₁, based on a consensus sequence of isolates of the avian-like A/swine/Guangxi/3843/2011 (H1N1) influenza virus (Sun 2020, (Gene Bank Acc #KM028359). The codon-optimized sequence was synthesized and cloned into expression vector pTZM26, providing an optimized secretion signal followed by a TEV-cleavable nona-histidine tag.

The plasmids were transiently transfected into serum free HEK293 cells (trenzyme GmbH) by use of FectoPro (Polyplus-transfection SA). Cells were cultivated in Erlenmeyer flasks of appropriate size at 37°C, 8% CO₂ shaking at 150 rpm for 4 days. Supernatants were clarified by centrifugation prior to loading onto the columns. The RBD proteins were IMAC purified by Ni Sepharose® excel resin (Cytiva). After washing with Phosphate buffer (pH 7.5) containing 500 mM NaCl and 10 mM imidazol, the bound (target) protein(s) were/was eluted using the same buffer containing 500 mM imidazol and relevant fractions were pooled after analysis by SDS-PAGE. The hACE2 protein was purified by ion exchange chromatography using Q-Sepharose FF (Cytiva) resin: after dilution of cell culture supernatant with equilibration buffer (50 mM Tris; pH 8.0) bound proteins were eluted by a linear gradient 0–100% buffer B (50 mM Tris, 400 mM NaCl; pH 8.0) over a volume of 30 CV (column volumes). hACE2 protein containing fractions were identified by SDS-PAGE and pooled accordingly. Following this purification step, the buffer of all proteins was exchanged to PBS, pH 7.4 using a HiPrep 26/10 desalting column (Cytiva) and proteins were aliquoted, (flash-)frozen and stored at -80°C.

Functional ELISA

ELISA plates (Nunc maxisorp) were coated with 200ng recombinant hACE2/well in coating buffer (50mM NaHCO₃ pH9) over night at 4°C. A standard sandwich ELISA protocol was performed using PBS with 3% BSA as blocking agent or with 0,05% Tween-20 as wash buffer. Serial dilutions of either purified RBD, or RBD or RBD-cCPE formulations containing Riboxxim™ (Riboxx Pharmaceuticals, Dresden), representative of the vaccine formulations used in the animal studies, were loaded to appropriate wells and incubated for 2h at RT. Monoclonal antibody CR3022 (Cat# Ab01680-23.0, Absolute Antibody Ltd) was used at concentration of 0,1µg/ml for detection of RBD, followed by addition of Goat-anti-Rabbit HRP (Cat#S2438, Sigma-Aldrich Chemie GmbH), staining with 100µl TMB (Cat#34028, Thermo Fisher Scientific). The reaction was stopped with stop with 50µl H₂SO₄ (50µl, 2M). Standard sandwich ELISA was performed using the same protocol but with coat antibody (Cat# 40150-D003, Sino Biological Europe GmbH, 25 ng/well) and detection antibody (HRP conugate antibody Cat# 40150-D001-H, Sino Biological Europe GmbH), followed by staining with TMB and stop with H₂SO₄. OD_{450nm} was determined using a Wallac Victor V multilabel reader (Perkin Elmer).

Riboxxim synthesis

The TLR3/RIG-I of Riboxxim™ was manufactured using a proprietary process as described previously (Kroemer 2021). Briefly, this process is an isothermal polymerization using an RNA-dependent RNA-polymerase and a single stranded RNA template, which yields perfectly annealed double stranded RNA consisting of 100bp. GMP-grade Riboxxim was stored at 4°C in water for injection at a concentration of 1 mg/ml.

Preparation of different formulations of monovalent SARS-CoV-2 RBD vaccines, and bivalent SARS/influenza H1HA₁ vaccines

Recombinant RBDs and Riboxxim were co-formulated in water for injection either as monovalent SARS vaccines, or bivalent SARS/influenza vaccines for injection (Table 1). For chitosan-adjuvantation, RBD and Riboxxim were co-formulated together with a 0.4 mg/ml chitosan solution. Since intranasally administered vaccines must be transported over a very small distance, remain in the nose only for about 15 min and are not exposed to low pH values, they do not necessarily have to be incorporated into chitosan microparticles, but may also be co-administered as chitosan solution (van der Lubben, 2001)

Animal immunization

For immunization studies 8–10 weeks old female BALB/c mice were immunized either subcutaneously at the base of the tail or intranasally under isoflurane anesthesia. Table 1 shows the different vaccine formulations for monovalent (SARS-CoV-2) vaccine formulations. Intranasal prime (day 0) and boost (day 21) vaccinations were performed by instilling 25µl of vaccine into each nostril. For systemic prime/intranasal boost, 50µl of vaccine were injected subcutaneously on day 0, and 25µl were instilled into each nostril on day 21. Nasal instillation of the vaccine was done under short (3-5min) isoflurane anesthesia. One week after the boost immunization mice were sacrificed, the trachea was cannulated,

and serum and target organs were collected for further analysis. The BALF was obtained by flushing the lungs with 800 µl PBS. The NALF was obtained by flushing the nostrils through the trachea with 400 µl PBS using an 18 G needle.

Determination of SARS-CoV-2 spike and RBD binding murine IgG antibodies by Luminex assay in serum, nasal lavage fluid (NALF) and broncho-alveolar fluid (BALF).

IgG antibody binding to immobilized analyte proteins was monitored by a Luminex bead-based assay, following the manufacturer's instructions with some proprietary modifications by Nanotools. Antigens used for antibody detection were recombinant RBD or trimeric spike protein derived from SARS-CoV-2, strain Wuhan-Hu-1 (trenzyme, Konstanz). Briefly, analyte proteins were conjugated to carboxylated Luminex beads via carbodiimide chemistry (nanoTools, proprietary protocol). In order to enable multiplexing in Luminex assays, each analyte protein was assigned a unique bead number, starting with 1000–2000 beads per assay point. All assays and washing steps were done in buffer V30 (nanoTools proprietary buffer). Mouse sera were initially diluted 1:200 and BALF and NALF 1:10, respectively, and then further diluted 8 times in 4-fold steps. 100 µl of each serum/BALF/NALF dilution was mixed with 100 µl of a suspension containing beads conjugated to monomeric RBD or trimeric spike protein, respectively, then incubated for one hour at room temperature, centrifuged and washed. In order to determine target specific IgG titers, the beads were then incubated with 1 µg/ml biotinylated subclass-specific goat anti mouse Ig in V30 buffer for one hour at room temperature and washed. Beads were resuspended in 1 µg/ml fluorochrome labelled Streptavidin in V30 buffer, incubated one hour at room temperature, washed and resuspended in 140 µl Luminex read buffer. Samples were analysed with Bioplex 100 / 200 instrumentation.

Endpoint titers (EP) were defined as highest sample dilution exceeding the signal of the mean of the control group (#9) + 3x standard deviation (SD). Log₁₀ EC₅₀ values were calculated using GraphPad Prism 7, using the 5-parameter logistic function (5PL). For mice with low titers, EC₅₀ could not be determined and log₁₀ EC₅₀ (IgG) was accepted as zero. Log₁₀ of endpoint titers or EC₅₀ were plotted with geometric mean ± geometric SD.

Determination of SARS-CoV-2 spike and RBD binding murine IgA antibodies by ELISA assay in serum, NALF and BALF.

RBD specific murine IgA antibody titers were determined by ELISA. Briefly, ELISA plates (Greiner) were coated with 20 µg/ml of recombinant RBD or trimeric spike protein derived from SARS-CoV-2, strain Wuhan-Hu-1 overnight at 4°C in PBS. Serial dilutions of mouse sera, BALF and NALF were prepared and loaded on the precoated plates at RT for 2 hours. For detection, ALP conjugated anti-mouse IgA mAb (MT39A-ALP, MabTech) was used according to the manufacturer's instructions followed by staining with 100 µl pNPP ELISA substrate (MabTech) for 1 hour at RT. OD_{405nm} was determined using an infinite M200PRO plate reader (TECAN). Endpoint titers were defined as highest sample dilution exceeding the signal of the mean of the control group + 3x standard deviation (SD).

Determination Of Rbd Specific T-cell Responses By Ifn γ Elispot Assay In Splenocytes

Frozen splenocytes of immunized mice were rapidly thawed, and the freezing medium was diluted into 14 ml of IMDM media (gibco), centrifuged and resuspended in 10ml of fresh IMDM media, supplemented with 10% FBS (gibco), 100U/ml Penicillin and 100 μ g/ml Streptomycin. Freshly thawed or freshly isolated splenocytes were incubated at 37°C for 1h, followed by centrifugation and resuspension in fresh media before being counted. Splenocytes were depleted of CD4⁺ or CD8⁺ T cells using MACS CD4 or CD8a microbeads (Miltenyi Biotech) according to the manufacturer's instructions. IFN γ production of SARS-CoV-2-Spike-RBD specific cells or HA₁ specific cells was analyzed using a commercially available mouse ELISPOT antibody pair (BD Bioscience) according to the manufacturer's instructions. Briefly, 1 \times 10⁶ to 2.5 \times 10⁵ splenocytes were incubated in pre coated MultiScreen® HTS PVDF Filter Plates (Merck Millipore) in triplicates and re-stimulated with 100 μ g/ml full length recombinant His-tagged SARS-CoV-2-Spike S1 (RBD) or His-tagged HA₁-H1N1 (HA). Negative controls were incubated with 100 μ g/ml recombinant His-tagged hACE2. at 37°C in a humidified CO₂ atmosphere for 24 hours. Following the incubation with a biotinylated secondary antibody specific for IFN γ , a streptavidin-alkaline phosphatase enzyme conjugate was added. With the addition of the BCIP®/NBT substrate solution (Sigma Aldrich), a purple precipitate is formed as spots at the sites of captured IFN γ . Automated spot analysis and quantification of developed plates were performed using the ImmunoSpot® S6ULTRA analyzer and ImmunoSpot® software version 7.0.33.1 (C.T.L. Europe).

Pseudotype Virus Preparation

Production of lentiviral pseudotyped viruses (PV) expressing the spike protein of either wildtype Wuhan-Hu1, or the variants B.1.1.7 (alpha) or B.1.351 (Beta) were carried out as previously described (Di Genova, 2021). Briefly, T-75 flasks containing HEK293T/17 cells at 50% confluency were co-transfected with 1 μ g of lentiviral Gag-pol p8.91 plasmid, 1.5 μ g of lentiviral vector expressing firefly luciferase pCSFLW, and 1 μ g of either WT, B.1.1.7 or B.1.351 spike plasmid in pcDNA3.1 + expression vector, using Fugene HD at a mixture ratio of 3:1 (DNA:Fugene HD) in 200 μ L Opti-MEM. Transfection mixtures were incubated for 15 minutes prior to addition into the flasks containing the cells. PVs were then harvested 48h post transfection by filtering the culture medium through a 0.45- μ m cellulose acetate filter. PVs were aliquoted and stored at -80°C. PV titers were obtained via a 2-fold serial dilution, then adding HEK293T/17 cells expressing ACE2/TMPRSS2 at a density of 10,000 cells per well. After 48 hours, cells were lysed using BrightGlo (Promega) and luciferase expression was measured using a GlowMax Navigator (Promega) luminometer.

Serum/plasma Pseudotyped Virus Neutralization Assay

PV neutralization assays were carried out as previously described (Di Genova, 2021). Briefly, heat inactivated BALF or sera obtained from mice were mixed at a 1:40 dilution in DMEM and a 2-fold serial dilution was carried out in a 96-well plate to a final dilution of 1:5120. PVs were then added (10^5 RLU/well) to the wells and plates were incubated at 37°C for 1 hour prior to addition of pre-transfected HEK293T/17 cells expressing ACE2/TMPRSS2 at a cell density of 10,000 cells per well. Plates were incubated for 48 hours at 37°C and 5% CO₂. After 48 hours, culture media was removed, and luminescence was measured using the Bright-Glo Luciferase assay system (Promega). Neutralization was calculated relative to virus only controls. Dilution curves were presented as a mean neutralization with standard error of the mean (SEM). IC₅₀ values were calculated in GraphPad Prism (Ferrara 2018). The IC₅₀ within groups were summarized as a geometric mean titer and statistical comparison between groups were made with Wilcoxon ranked sign test. In addition, the impact of the mutations on the neutralizing effect of the sera were expressed as fold change (FC) of IC₅₀ of the wild-type compared to mutant pseudotyped virus. Statistical difference in the mean FC between groups was determined using a 2-tailed t-test.

Animals and ethics statement

BALB/cAnNCrl (BALB/c) mice were originally purchased from Charles River (Sulzfeld, Germany) and were further bred in the accredited animal facility of the University of Konstanz under specific pathogen-free conditions. Mice were kept in air-conditioned rooms with controlled temperature (22°C), 55% relative humidity, and constant ventilation (17 air changes/h). Animals were provided ad libitum access to standard, autoclaved laboratory animal diet, and tap water. Female mice were used at 8–10 weeks of age. The number of animals in each group was determined according to statistical verification and previous studies. Animal experiments were conducted in compliance with ethical standards of German and EU guidelines after approval by the animal experimentation ethics committee of the Review Board of Governmental Presidium Freiburg, Germany (approval numbers G-20/142, G-21/119), equivalent to the ARRIVE guidelines.

Statistical methods

Two-way comparisons using the Mann-Whitney U test was done for serological results (endpoint titers and EC50). ELISPOT counts were compared groupwise by one-sided ANOVA, followed by Tukey's multiple comparison test.

Discussion

First-generation SARS-CoV-2 vaccines based on mRNA or recombinant adenoviral vectors provide a high level of protection against severe disease, hospitalization, and death. However, rapidly waning immunity, clinically relevant break-through infections, especially with emerging variants, and shedding of high levels of virus by asymptotically infected, fully vaccinated persons are cause for concern with respect to the long-term control of COVID-19 (*Kustin 2021, Hacisuleyman 2021, Altmann 2021, Siedner 2022*). In SARS-

CoV-2 infection, mucosal antibodies against spike (S) and RBD increase 7–9 days after symptom onset, remain elevated for at least 9 months and were found to be correlated with a lower viral load and a faster decline in systemic symptoms (*Fröberg 2021, Huang 2021*). In contrast, all but one currently approved COVID-19 vaccines mediate protection through systemic virus neutralizing antibodies and likely also virus-specific T-cells, but induce only low mucosal IgA responses, as shown in a recent study of recipients of the BNT162b2 COVID-19 mRNA vaccine (*Azzi 2022, Chan 2021, Wherry 2022*). This lack of mucosal immunity was further confirmed by the observation that fully vaccinated index cases with breakthrough infections transmitted the virus to household contacts at a similar rate as unvaccinated index cases of approx. 25% (*Singanayagam 2022*). The emergence of novel variants such as omicron indicates that SARS-CoV-2 is continuing to mutate and evolve to subvert existing immune responses and increase transmissibility. Therefore, regular booster immunizations will be required to prevent severe disease and curb spread of the virus even in populations with a high level of pre-existing partial immunity, acquired either through vaccination or natural infection (*COVID is here to stay. Nature Editorial 2022, Reynolds 2022*). Second generation COVID-19 vaccines that confer broad protection, can easily be mass produced and deployed, and are user-friendly, offer the prospect of containing the virus in the long-term.

To this end, we designed a novel intranasal vaccine candidate based on the recombinantly expressed receptor binding domain (RBD) of SARS-CoV-2, fused to a polypeptide to specifically target antigen uptake by microfold cells (M-cells) of the nasal and bronchial-associated lymphoid tissue (NALT, BALT), and adjuvanted it with a novel toll-like receptor 3/RIG-I agonist consisting of short, double-stranded RNA.

The RBD, against which approx. 90% of the SARS-CoV-2 neutralizing antibody response is directed, has previously been identified as an ideal antigen for next generation Covid vaccines in multiple preclinical and clinical studies (*Piccoli 2020, Kleanthous 2021*). Since recombinant proteins typically induce no or only weak immune responses in the nasal mucosa (*Neutra 2006*), we increased the immunogenicity by fusing the RBD to a short polypeptide derived from the C-terminus of the *Clostridium perfringens* toxin (cCPE), which targets highly expressed claudin-4 on microfold cells (M-cells) and has previously been described to enhance the immunogenicity of intranasal pneumococcal and influenza vaccines (*Suzuki 2015, Lo 2012*). M-cells are specialized epithelial cells, localized in mucosal crypts of the NALT and BALT, that carry sample antigen and transport it across the mucosa to adjacent antigen-presenting cells (APC), including dendritic cells, and are therefore attractive target cells for mucosal immunization (*Fujimura 2004, Dillon 2019, Islam 2019, Brandtzaeg 2011, Palucka 2010*). Processed antigen is presented to CD4 + T cells in the lymphoid tissues that can induce IgA-committed B-cell development in the lymphoid follicle. Targeting the RBD to M-cells increased antibody titers of our vaccine in all compartments measured, with up to 11.9-fold and differences of GMTs between non-targeted and targeted RBD for IgG.

The vaccine induced robust mucosal and systemic antibody responses and systemic CD4 and CD8 T-cell responses, when given either in as an intranasal prime/intranasal boost, or as a subcutaneous prime/intranasal boost. Spike-binding and pseudotyped-virus neutralizing systemic IgG antibody titers were equivalent to those induced in mice by two doses of mRNA or adenoviral vaccines, with similar neutralizing titers against wildtype Wuhan-Hu-1, the alpha variant B.1.1.7, and the delta variant B.1.617.2.

We observed an approx. 10-fold drop of neutralizing titers against the beta variant B.1.351, which has been also reported for mRNA vaccines (*Liu 2022*).

In humans, most experience with experimental mucosal adjuvants has been gained with intranasal influenza vaccines adjuvanted with heat labile toxin of *E.coli* (LT), and toll-like receptor agonists such as monophosphoryl lipid A (TLR4), CpG (TLR9) and poly-IC:LC (TLR3) (*Ainai 2011, Suzuki 2017*). Only LT was used in a commercial product, however, that vaccine (NasalFlu) to be withdrawn from the market due to an increased occurrence of Bell's palsy (*Mutsch 2004*). The potential toxicity of mucosal adjuvants for intranasal application is therefore of concern and must be considered when developing intranasal vaccines. To this end, TLR3 adjuvants have been safely tested in non-human primates and in phase 1 trials in humans, both as influenza vaccine adjuvants as well as unspecific prophylactic monotherapy in human challenge models with influenza and rhinovirus (*Ichinohe 2010, Overton 2014*). Importantly, intranasal administration of TLR3 agonists as monotherapy in humans at more than 100-fold higher doses (up to 6.4mg) than used in our study was not associated with safety or tolerability issues (*Malcolm 2018*). Interestingly, TLR3 is involved in mucosal IgA antibody induction not only in a CD4 T-cell dependent manner via stimulation of CD103+ dendritic cells, but also in a T-cell independent manner via direct stimulation of extrafollicular mucosal B-cells that were shown to undergo rapid class-switch recombination when stimulated with double-stranded viral RNA (*Xu 2008, Takaki 2018*). Riboxim agonists may therefore be an ideal mucosal adjuvant for the induction of rapid IgA responses.

To further evaluate the versatility of our vaccine platform, we co-formulated a SARS-CoV-2 RBD / Influenza H1-HA1 vaccine, with both antigens targeted to M-cells, and adjuvanted with Riboxim. A HA1 consensus sequence derived from 25 isolates of the influenza strain A/swine/Guangxi/3843/2011 (H1N1) was chosen, because G4 Eurasian (EA) avian-like H1N1 viruses have been spreading in pigs in China since 2016 and are considered a potential pandemic threat (*CDC 2020*). The combination vaccine induced high SARS-CoV-2 binding and neutralizing antibody titers in serum, NALF and BALF, including against the delta variant, which were very similar to those observed with the monovalent vaccine. In addition, the vaccine induced mucosal IgA and high systemic IgG antibodies binding monomeric recombinant HA₁ protein. These data show that the combination of two different M-targeted vaccine antigens does not seem to result in immunodominance, which suggests that development of an intranasal vaccine protecting against multiple viruses may be feasible.

In summary, our novel vaccine platform overcomes the shortcomings of previous recombinant protein based intranasal vaccines by combining M-cell targeting of the vaccine antigen with a TLR3 agonist. This vaccine can be used for intranasal boosting following an intranasal or subcutaneous boost, induces systemic immune responses comparable to mRNA vaccines, is temperature stable, and can potentially be self-administered with an appropriate device. As such, it could play an important role in long-term containment of the virus.

Declarations

ACKNOWLEDGEMENTS

The Viral Pseudotype Unit receives funding from the Wellcome Trust, the MRC and the Bill & Melinda Gates Foundation.

Authors contributions

JtM, RH and JR designed the study, analyzed the data and wrote the manuscript. AG, AB, JM, BJ provided recombinant proteins and performed and analyzed ELISA assays. HH performed and analyzed MSD assays. NT, MMN, KdC and DC designed and developed the lentiviral pseudotypes for SARS-CoV-2 and performed and analyzed the associated serological assay data. DH and MG performed the animal experiments and analyzed ELISPOT assays and analyzed the data.

Acknowledgements

DH is funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) under Germany's Excellence Strategy, EXC2117-422037984.

Availability of data and materials

The DNA sequences of the vaccine constructs have been deposited in GenBank under accession numbers: BankIt2646502 RBD OP896053; BankIt2646502 HA1-cCPE OP896054; BankIt2646502 RBD-cCPE OP896055

Competing interest statement

RH, JR and JtM are inventors on a patent application relating to a M-cell targeted SARS-CoV-2 and H1-influenza virus vaccine. DH, NT, MMN, KDC, DC, AG, AB, JM, BJ, MG, and HH declare no conflict of interest.

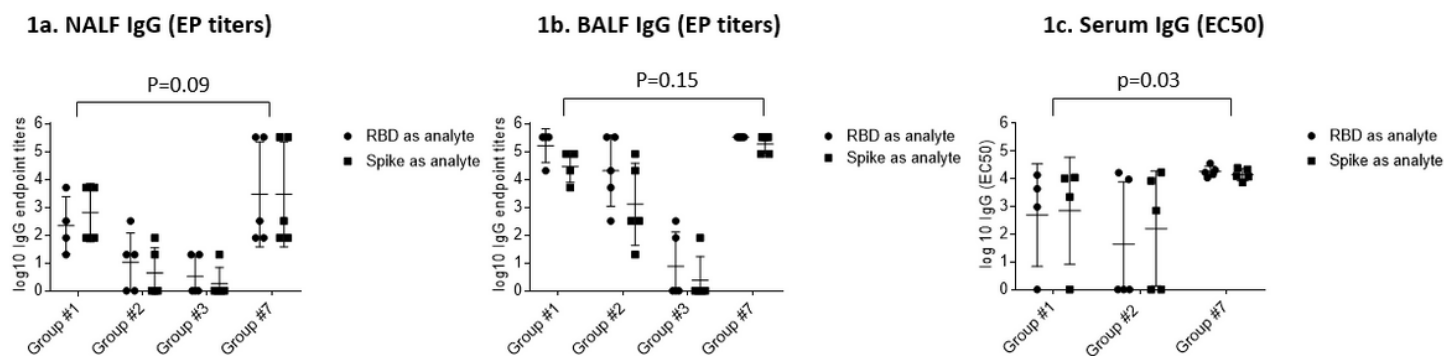

Figure 1

Monovalent SARS-CoV-2 RBD vaccines induce IgG antibody responses in NALF, BALF and serum

Mice were prime-boost immunized intranasally with non-targeted (nt) RBD, strain Wuhan-Hu-1 (group #1) or primed subcutaneously and boosted intranasally with nt RBD (group #2), or prime-boosted intranasally with nt RBD, adjuvanted with Riboxxim and Chitosan (group #3), or prime-boosted intranasally with M-cell targeted RBD (RBD-cCPE, group #7). All vaccines were adjuvanted with Riboxxim. Sera, nasal fluid (NALF) and bronchioalveolar fluid (BALF) were obtained on day 28, one week after the boost, diluted in 4-fold

steps, and assayed for IgA antibodies in a Luminex assay with recombinant nt RBD, or recombinant trimeric spike protein, both derived from SARS-CoV-2 strain Wuhan-Hu-1. Endpoint titers (EP) were defined as highest sample dilution exceeding the signal of mean of control group (#9)+3xSD. Log10 EC50 values were calculated using GraphPad Prism 7, 5PL. For mice with low titres, EC50 could not be determined and log10 EC50 (IgG) was accepted as zero. Log10 of endpoint titers or EC50 were plotted with geometric mean± geometric SD.

Figure 2

Monovalent SARS-CoV-2 RBD vaccines induce IgA antibody responses in NALF, BALF and serum

Mice were prime-boost immunized intranasally with non-targeted (nt) RBD, strain Wuhan-Hu-1 (group #1), or M-cell targeted RBD (RBD-cCPE, group #7). Both vaccines were adjuvanted with Riboxsim. Sera were obtained on day 28, one week after the boost, diluted in 4-fold steps, and assayed for IgA antibodies in Luminex with recombinant nt RBD, or recombinant trimeric spike protein, both derived from SARS-CoV-2 strain Wuhan-Hu-1. Endpoint titers (EP) were defined as highest dilution of a sample exceeding the mean signal of the lowest 2 dilutions + 3SD. Log10 of endpoint titers were plotted with geometric mean± geometric SD.

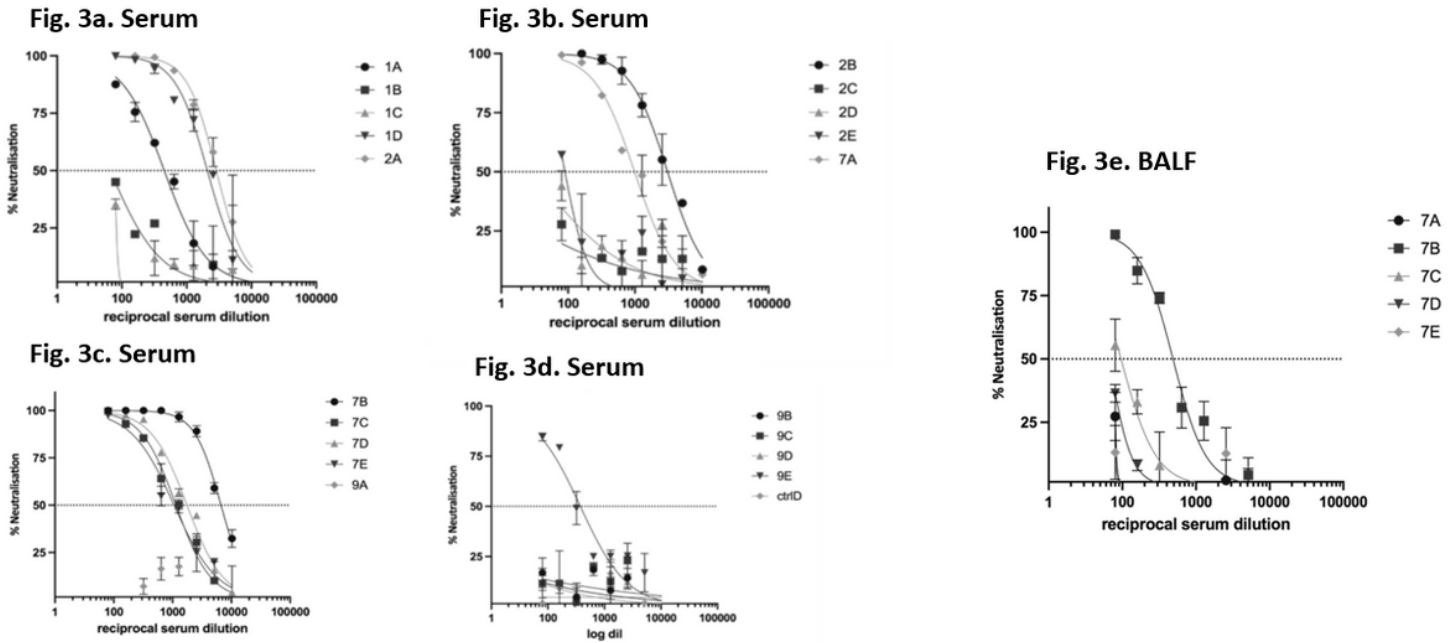

Figure 3

Monovalent SARS-CoV-2 RBD vaccines induce SARS-CoV-2 pseudovirus (Wuhan-Hu-1) neutralizing antibodies in serum and BALF

Mice were prime-boost immunized intranasally with non-targeted (nt) RBD, strain Wuhan-Hu-1 (group #1), or M-cell targeted RBD (RBD-cCPE, group #7), and sera and BALF obtained on day 28, one week after the boost, diluted in 10-fold steps, and assayed for neutralization of SARS-CoV-2 pseudoviruses (PV). The spike protein sequence was derived from SARS-CoV-2 strain Wuhan-Hu-1. Fig.3a (mice group #1): Serum, intranasal prime-boost immunization with nt RBD plus Riboxxim. Fig.3b (group #2): Serum, subcutaneous prime-intranasal boost immunization with nt RBD plus Riboxxim. Fig.3c (group #7): Serum, intranasal prime-boost immunization with M-cell targeted RBD (RBD-cCPE) plus Riboxxim. Fig.3d (group #9): Serum, control mice. Fig.3e (group #7): BALF, intranasal prime-boost immunization with RBD-cCPE plus Riboxxim.

Figure 4

Monovalent SARS-CoV-2 RBD-cCPE vaccine induces antibodies neutralizing SARS-CoV-2 pseudotypes B.1.1.7 and B.1.351

Mice were prime-boost immunized intranasally with M-cell targeted RBD (RBD-cCPE, group #7), and sera and BALF obtained on day 28, one week after the boost, diluted in 10-fold steps, were assayed for neutralization of pseudotype viruses. The spike protein sequence was derived from SARS-CoV-2 strain Wuhan-Hu-1, strain B.1.1.7 (Alpha), or B.1.351 (Beta). Fig.4a and 4b. Serum neutralization. Fig.4c. BALF neutralization. Fig.4d. Comparison of serum neutralization of SARS-CoV-2- PV wildtype (Wuhan-Hu-1), alpha, and beta variants.

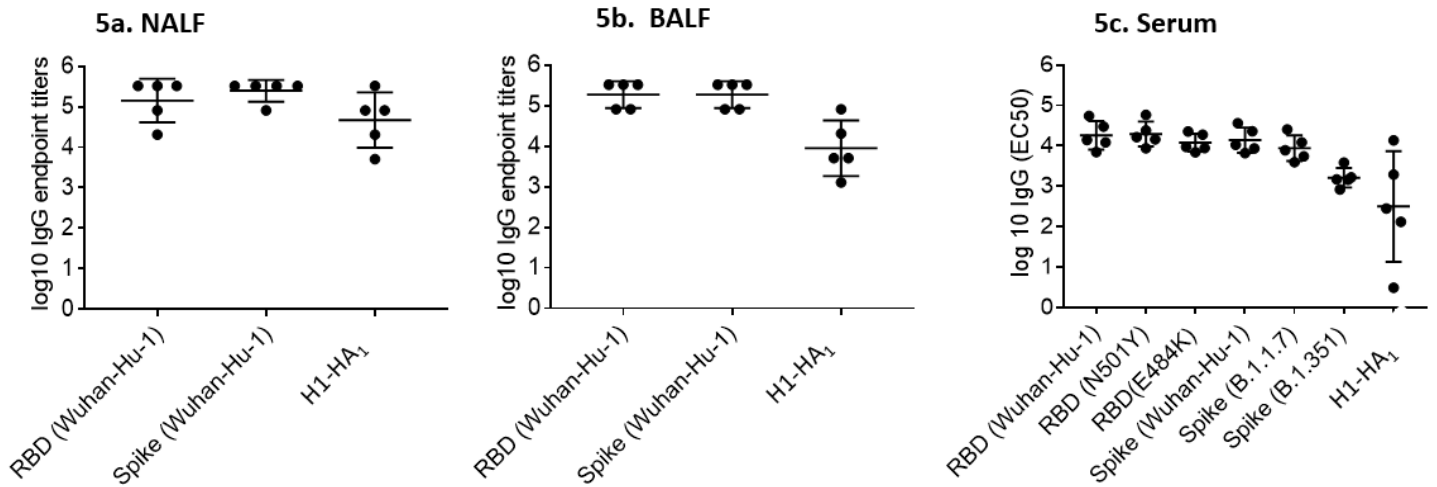

Figure 5

Bivalent SARS-CoV-2 RBD-cCPE/Influenza H1-HA1-cCPE vaccine induces IgG antibody responses in NALF, BALF and serum against RBD and spike of SARS-CoV-2 wildtype and variants

Mice were prime-boost immunized intranasally (days 0 and 28) with bivalent SARS-CoV-2 RBD-cCPE / influenza H1-HA1-C-CPE vaccine, adjuvanted with Riboxsim. NALF, BALF and sera were obtained on day 28, one week after the boost, diluted in 4-fold steps, and assayed for IgG antibodies in Luminex with recombinant monomeric RBD (Wuhan-Hu-1/wildtype, or point mutations N501Y, or E484K), or recombinant trimeric spike protein (Wuhan-Hu-1, B.1.1.7, B.1.351), or recombinant monomeric H1-HA1 (A/swine/Guangxi/3843/2011(H1N1), respectively). Endpoint titers (NALF, BALF) or EC₅₀ (serum) were calculated where applicable. Log₁₀ of endpoint titers or EC₅₀ were plotted with geometric mean ± geometric SD.

Figure 6

Monovalent influenza H1-HA1 and bivalent SARS-CoV-2 RBD/influenza H1-HA1 vaccines induce IgA antibody responses in NALF, BALF and serum

Mice (n=5/group) were prime-boost immunized intranasally (days 0 and 28) with monovalent influenza H1-HA1-cCPE or bivalent SARS-CoV-2 RBD-cCPE / influenza H1-HA1-cCPE vaccine, adjuvanted with Riboxim. NALF, BALF and sera were obtained on day 28, one week after the boost, diluted in 4-fold steps, and assayed for IgG antibodies ELISA with recombinant monomeric RBD (Wuhan-Hu-1/wildtype), recombinant trimeric spike protein, or recombinant monomeric H1-HA1 (A/swine/Guangxi/3843/2011(H1N1), respectively). Log10 of endpoint titers were plotted.

Figure 7

Bivalent SARS-CoV-2 RBD-cCPE/influenza H1-HA1-cCPE induces SARS-CoV-2 pseudovirus (Wuhan-Hu-1) neutralizing antibodies in NALF and BALF and serum

Mice were prime-boost immunized intranasally (days 0 and 28) with bivalent SARS-CoV-2 RBD-cCPE / influenza H1-HA1-cCPE vaccine, adjuvanted with Riboxim. NALF, BALF and sera were obtained on day 28, one week after the boost, diluted in 4-fold steps, and assayed for neutralization of SARS-CoV-2 pseudoviruses. The spike protein sequence was derived from SARS-CoV-2 strain Wuhan-Hu-1.

Figure 8

Bivalent SARS-CoV-2 RBD-cCPE/influenza H1-HA1-cCPE induces SARS-CoV-2 pseudovirus (Delta variant B.1.617.2) neutralizing antibodies in NALF and BALF and serum

Mice were prime-boost immunized intranasally (days 0 and 21) with bivalent SARS-CoV-2 RBD-cCPE / Influenza H1-HA1-cCPE vaccine, adjuvanted with Riboxxim. NALF, BALF and sera were obtained on day 28, one week after the boost, diluted in 10-fold steps, and assayed for neutralization of SARS-CoV-2 pseudoviruses. The spike protein sequence was derived from SARS-CoV-2 strain B.1.617.2)

Figure 9

Monovalent SARS-CoV-2 RBD-cCPE and bivalent SARS-CoV-2 RBD-cCPE/Influenza H1-HA1-cCPE vaccines induces CD4 and CD8 T-cell responses against recombinant SARS-CoV-2 RBD or influenza H1-HA1

A) Mice were prime-boost immunized intranasally (days 0, 21) with either monovalent non-targeted RBD, strain Wuhan-Hu-1 (group #1), M-cell targeted RBD (RBD-cCPE, group #7), both adjuvanted with Riboxxim or PBS (group #9). On day 28 bulk splenocytes (Bulk, squares) or splenocytes MACS-depleted for either CD8 (CD4, rhombus) or MACS-depleted for CD4 (CD8, triangles) were analyzed for IFN γ production upon restimulation with recombinant RBD or recombinant ACE2 as control (Neg, dots) in ELISPOT. Data are presented as means + SD. Statistics: two-way ANOVA followed by Tukey's multiple comparisons test with ns = not significant; *** $P \leq 0.001$; **** $P < 0.0001$. B) Mice were prime-boost immunized intranasally with bivalent SARS-CoV-2 RBD-cCPE / influenza H1-HA1-cCPE, adjuvanted with Riboxxim. On day 28 splenocytes were analyzed for IFN γ production upon restimulation with recombinant RBD (dots) derived from SARS-CoV-2 strain Wuhan-Hu-1 or an H1-HA1 consensus sequence (squares) protein in ELISPOT. Data are presented as means + SD. Statistics: Unpaired t-test, ns = not significant
