Abstract

Background

Postpartum dysgalactia syndrome (PDS) is associated with a significantly higher activation of the inflammatory and stress response at parturition than in the healthy sow. Therefore, reliable and possibly non-invasive biomarkers for substantial increases of inflammation are searched to support the PDS diagnosis. This report studies the possible changes of the inflammatory marker enzyme adenosine deaminase (ADA) in serum and saliva of 38 PDS positive sows (PDS+) and 38 healthy sows (PDS⁻). Sampling was performed every 24 h from 60 h before to 36 h after parturition. Isoenzyme 1 (ADA1) and isoenzyme 2 (ADA2), as well as total ADA (tADA) were measured and their statistical association with several serum and saliva biomarkers of inflammation and stress was investigated.

Results

Compared to a baseline (60 h to 36 *prepartum*), salivary activities of ADA1, ADA2 and tADA increased significantly over time in both PDS+ and PDS⁻ sows, reaching their peaks after parturition. In serum from PDS⁻ sows, no changes were observed over time in either ADA1, ADA2 or tADA. In PDS+ sows, serum ADA2 activity decreased temporarily after parturition followed by a significant increase compared to baseline. ADA1, ADA2 and tADA were all significantly associated with several inflammatory biomarkers and ADA1 in serum was associated with serum cortisol. Although serum activity was higher in PDS+ than in PDS⁻ sows, the differences were not statistically significant. Further, no difference was noted between the groups in the analyses of saliva.

Conclusions

Salivary ADA1 and ADA2 increased in all sows after parturition, potentially as a response to the postpartum inflammation. However, no difference in the activity of ADA1, ADA2 and tADA were found between PDS+ and PDS⁻ sows indicating inability to diagnose PDS under the conditions described in this report.

Background

Adenosine deaminase (ADA, EC number 3.5.4.4) is an enzyme present in most organic tissues, especially those of lymphoid origin [1]. Two isoenzymes have been described, of which isoenzyme 1 (ADA1) is the predominant form in lymphoid tissues. ADA1 mediates B and T cell differentiation [2] and macrophage maturation [3, 4]. Although isoenzyme 2 (ADA2) function is poorly understood, it seems to be involved in reactions by the haematopoietic system [5, 6] and regulation of the immune system, since lack of ADA2 can lead to immunosuppression and autoimmune conditions [7, 8]. Increased ADA activity has been proposed as a biomarker of cell-mediated immunity, and its increase in serum can be considered a marker of inflammation [9]. In humans, increased ADA activity has been found in several inflammatory disorders such as tuberculosis [10], visceral leishmaniasis [11], celiac disease [12], ulcerative colitis [13], typhoid fever [14], and malignancies [15–17].

Saliva is commonly used in studies on stress in humans and animals since its collection causes a minimum of disturbance [18]. However, saliva can also be used to measure biomarkers for systemic alterations such as inflammation [19]. Increased ADA activity has been found in saliva in humans with oral malignancies [20] and Sjögren's syndrome [21]. Salivary ADA increased in bitches with pyometra and in pigs with lameness, whereas no increase was found in sera from the same animals [22]. ADA activity was more than 100-fold higher in pig saliva than in serum. In addition, since a correlation between salivary ADA and serum ADA seems to be absent, it is possible that ADA, sampled from the oral cavity, could provide information that differ from that of ADA from serum [23]. Thus, saliva ADA may be expected to be a useful marker of inflammation in pigs.

The postpartum dysgalactia syndrome (PDS) is a common disorder in sows, appearing within the first 72 h after parturition [24]. The pathogenesis of PDS is insufficiently elucidated, as lined out by Martineau et al. [25]. Yet, activation of the stress systems (sympathetic adrenomedullary and hypothalamic adrenocortical axes), oxidative stress, metabolic changes due to low energy intake, and inflammation have been suggested to be involved in the pathogenesis of PDS [26–28].

To the authors' knowledge, ADA has not yet been studied in sows with PDS, and its use as an inflammatory biomarker during these conditions is unknown. The objective of the present study was therefore to evaluate ADA's potential as an inflammatory marker in sows suffering from PDS.

For this purpose, activities of the ADA1 and ADA2 isoenzymes and of total ADA (tADA) in saliva and serum obtained throughout the periparturient period of 38 PDS affected (PDS+) and 38 healthy (PDS-) sows, were analyzed. In addition, the association between the levels of ADA and other inflammatory and stress markers was evaluated.

Results

Saliva

The results obtained in saliva are given in Table 1 along with all *p*-values. Compared to baseline A (÷ 60 to ÷ 36 h), salivary activity of ADA1, ADA2 and tADA increased significantly during the first 36 hours *p.p.* investigated in this study, in both the PDS + and the PDS - sows. In the healthy sows, ADA1 and tADA increased significantly in the period D (÷ 12 to 0 h) with the highest values obtained in the periods E (0 to 12 h) and F (12 to 24 h), respectively. ADA2 increased significantly from baseline and peaked in period E. In the PDS + group, ADA1, ADA2 and tADA were significantly increased in period E (0 to 12 h) as compared to the baseline values, and the highest value was obtained in period F (12 to 24 h). There were no significant differences between the PDS + and PDS - sows in the activities of ADA1, ADA2 and tADA.

Table 1

Mean adenosine deaminase 1 (ADA1), adenosine deaminase 2 (ADA2) and total adenosine deaminase (tADA) activities (IU/L) in saliva from 38 sows with postpartum dysgalactia syndrome (PDS+) and 38 healthy sows (PDS-) in the periparturient period. Values for period B to G are compared to baseline (period A), where 0 h is the birth time of the first piglet and significant differences are indicated by the *p*-values

Serum

The results of the serum analyses are shown in Table 2. In the PDS + sows, serum ADA2 activity was significantly decreased in period E (0 to 12 h), followed by a significant increase in the periods F (12 to 24 h) and G (24 to 36 h). In contrast, there were no changes over time in serum ADA1 and tADA activity when compared to baseline A (÷ 60 to ÷ 36 h). No changes were observed in either ADA1, ADA2

or tADA throughout the study in the PDS ÷ sows. There was no significant difference between the PDS + and the PDS ÷ sows with respect to ADA2, ADA1 and tADA activities (all *p*-values are given in Table 2).

Table 2

Mean adenosine deaminase 1 (ADA1), adenosine deaminase 2 (ADA2) and total adenosine deaminase (tADA) activities (IU/ml) in serum from 38 sows with postpartum dysgalactia syndrome (PDS+) and 38 healthy sows (PDS÷) in the periparturient period. Values for period B to G are compared to baseline (period A), where 0 h is the time of birth of the first piglet

[†] No significant interaction between *time* and *case-control* was found for ADA2 in serum. Therefore, an overall strong trend between PDS + and PDS÷ (*p* = 0.0514) was estimated using the statistic model B (OUTCOME PARAMETER_{ij} = μ + TIME_i + GROUP_j + ε)

Associations between ADA1, ADA2, tADA and concentrations of inflammatory markers in saliva and serum

Salivary ADA1, ADA2 and tADA were negatively associated with white blood cell counts (WBC) and with neutrophil and lymphocyte counts in plasma, and ADA1 and tADA were also negatively associated with iron (Fe) in serum. Salivary ADA1, ADA2 and tADA were positively associated with tumour necrosis factor α (TNF-α), interleukin 6 (IL-6), serum amyloid A (SAA), C-reactive protein (CRP), haptoglobin (Hp), albumin (ALB), serum cortisol, salivary cortisol, chromogranin A (CgA) and rectal temperature. No associations were found between any of the isotypes of ADA and 8-epi prostaglandin F2 Alpha (8-epi-PGF2 α) or heart rate (Table 3; *p*-values are given in the table).

Table 3

Association between adenosine deaminase 1 (ADA1), adenosine deaminase 2 (ADA2), total adenosine deaminase (tADA) as analysed in serum, and inflammatory, hormonal and clinical markers in saliva*, serum** and plasma*** from 76 sows in the periparturient period. Positive associations are indicated by (+) in front of the value analysed, and negative association are indicated by (÷) symbols.

In serum, ADA1 activity was positively associated with serum cortisol. ADA2 were negatively associated with WBC, neutrophil and lymphocyte counts, and positively associated with TNF- α , IL-6, SAA, CRP, Hp, serum cortisol and rectal temperature. Activity of tADA was negatively associated with WBC, neutrophil and lymphocyte counts, and positively associated with TNF- α , SAA, serum cortisol and rectal temperature (Table 3; *p*-values are given in the table).

Discussion

The occurrence inflammatory response during the parturition process has previously been described for sows [29, 30], mares [31], cows [32] and humans [33]. Due to the significant changes observed in ADA1, ADA2 and tADA activities throughout the periparturient period in both the PDS + and the PDS ÷ sows, saliva ADA seems to reflect this inflammatory response in sows. In line with this, similar significant changes in several other inflammatory biomarkers in serum and saliva of healthy sows during the periparturient period have been described [26]. We have previously demonstrated that the inflammatory response was activated from 12 h *ante partum* and peaked 12 to 36 h *post partum* [26]. Similarly, others have demonstrated numerical and significant variation of inflammatory markers before parturition [29, 34].

Increased serum ADA activity at the end of gestation and in the periparturient period may be explained by two mechanisms. One is the synthesis by the placenta, since ADA is produced in the placenta and serum levels have shown to increase during pregnancy in humans [35, 36]. Another explanation could be inflammation-related synthesis of ADA, as suggested by our results. The relation to inflammation is, however, not entirely clear, as although Fávéro et al. [32] demonstrated increased ADA activities in cows at the end of pregnancy and after calving, other reports were not able to demonstrate any increase in serum ADA during inflammatory conditions [22, 23].

Although values of salivary ADA were higher in the PDS + than in the PDS ÷ sows, the differences were not statistically significant. This may be due to the high inter-individual variability observed in the animals. Similarly, although serum ADA2 tended to differ between PDS + and PDS ÷ sows, this marker appears unsuitable for the use in the diagnosis of PDS. Therefore, ADA in our clinical setting was of lower value in the differentiation between PDS + and PDS ÷ sows as compared to other inflammatory markers, that previously demonstrated their ability to differentiate between these sows [26, 28].

The significant associations between salivary ADA1, ADA2 and other inflammatory markers corroborate that these isoenzymes are indeed markers of inflammation in sows. This is in agreement with previous studies showing an increased salivary ADA activity in pigs undergoing inflammatory processes [22, 23]. In contrast, serum ADA1, ADA2 and tADA appears to be less suitable markers of inflammation in sows.

Conclusions

Salivary activity of ADA1 and ADA2 increased in sows after parturition and the activities were associated with the concentrations of several inflammatory markers. This supports the role of ADA as a marker of inflammation, but activities of ADA1, ADA2 and tADA did not significantly differ between PDS + sows and PDS ÷ sows. Further investigations are needed on the cause of the increased enzyme activity during the periparturient period, on the significance of ADA as an inflammatory marker, and its excretion from placenta.

Methods

Study design

This study included saliva and sera from sows sampled in a Danish sow farm as previously described by Kaiser et al. [26, 27, 37]. Briefly, PDS + sows ($n = 38$) and PDS ÷ sows ($n = 38$) were sampled once a day from 2 days before parturition until the development of PDS, or for a maximum of 2 days after parturition. Before each morning feeding, saliva was sampled by additive-free cotton swabs (Salivette® Cortisol, Hounissen, Denmark), immediately centrifuged for 5 min at $1,000 \times g$, and stored at $\div 80^{\circ}\text{C}$ until analysis for CgA and cortisol as previously described [26]. After the morning feeding, each sow underwent a thorough clinical examination that included measurements of the body temperature and the heart rate. Thereafter, blood was sampled from *v. jugularis* using tubes with the addition of EDTA (BD, New Jersey, US) for the analyses of total WBC, lymphocyte and neutrophil counts, and additive-free tubes (BD, New Jersey, US) were centrifuged at $3,000 \times g$ for 10 min. and used in the analyses of serum cortisol, Fe, ALB, IL-1, IL-6, TNF- α , SAA, Hp, CRP, and 8-epi-PGF 2α , as previously described [26]. In the statistical analyses, the samples were retrospectively divided into seven different periods in relation to parturition of the first piglet (0 h): A. ($\div 60$ to $\div 36$ h); B. ($\div 36$ to $\div 24$ h); C. ($\div 24$ to $\div 12$ h); D. ($\div 12$ to 0 h); E. (0 to 12 h); F. (12 to 24 h); and G. (24 to 36 h p.p.). Based on the clinical examinations, the sow was diagnosed with PDS (PDS+) if she fulfilled two out of three criteria: 1) reduced appetite (the trough were not emptied within 30 minutes after feeding); 2) inflammation of the udder (redness, swelling and increased skin temperature of the udder); 3) rectal temperature $\geq 39.5^{\circ}\text{C}$.

Based on the same criteria, the PDS + sows were retrospectively matched with sows that remained healthy (PDS÷) according to Kaiser et al.

[26].

ADA analyses

Saliva and serum were analysed for ADA1, ADA2 and tADA activities using a commercially available, spectrophotometric, automated assay (Adenosine Deaminase assay kit, Diazyme Laboratories, Poway, CA), based on the method described by Galanti et al. [38]. In the analyses of ADA2 and tADA, the measurements were performed in the presence and absence, respectively, of erythro-9-(2-hydroxy-3-nonyl) adenine (EHNA), a specific ADA1 inhibitor [39] and ADA1 was calculated as the difference between the two measurements. The method was adapted to an automated analyzer (Olympus AU400, Olympus Diagnostica GmbH, Ennis, Ireland) following the manufacturer's instruction with some modifications for its use in porcine saliva [22].

Statistical analyses

Two autoregressive linear regression models (A and B) were used in the statistical analysis by the PROC MIXED procedure of Statistic Analytical Software, Enterprise Guide 7.1 (SAS® Institute, Cary, North Carolina, USA).

Model A: $OUTCOME\ PARAMETER_{ij} = \mu + TIME_i + GROUP_j + TIME*GROUP_{ij} + \epsilon_{ij}$, where $OUTCOME\ PARAMETER_{ij}$ indicates ADA1, ADA2, tADA values for salivary and serum; μ was the value of the observations at time 0; $TIME_i$ was the explanatory variable time intervals (A to G); $GROUP_j$ was the explanatory variable "PDS+/PDS÷"; $TIME*GROUP_{ij}$ was the interaction between "PDS+/PDS÷" and time intervals (A to G), and ϵ_{ij} was the random residual error term. If significant interaction occurred by the use of model A, differences between PDS + and PDS ÷ and differences between the seven different time intervals were accepted. In case of non-significant interaction, model B was used instead of model A: $OUTCOME\ PARAMETER_{ij} = \mu + TIME_i + GROUP_j + \epsilon_{ij}$. The effect was considered non-significant if changes in $TIME_i$ were non-significant. The significance level was $p < 0.05$. The sows body condition score and parity were incorporated as explanatory variables. To improve normality of residuals plots, natural logarithm transformation was used in the analysis of ADA1 (salivary and serum), ADA2 (salivary) and tADA (salivary and serum).

The association between the values of ADA1, ADA2, tADA (salivary and serum) and WBC, neutrophils, lymphocytes, TNF- α , IL-6, SAA, CRP, Hp, Fe, ALB, 8-epi-PGF2 α , cortisol (salivary and serum), CgA, rectal temperature and heart rate was tested by a regression analysis in the PROC MIXED procedure of Statistic Analytical Software, Enterprise Guide 7.1 (SAS® Institute, Cary, North Carolina, USA).

Abbreviations

ADA: Adenosine deaminase (ADA1 for isoenzyme 1, ADA2 for isoenzyme 2, and tADA for total activity)

ALB: albumin

CgA: chromogranin A

CRP: C-reactive protein

EHNA: erythro-9-(2-hydroxy-3-nonyl) adenine

8-epi-PGF2 α : 8-epi prostaglandin F2 Alpha

Fe: iron

Hp: haptoglobin

IL-6: interleukin 6

LSMEANS: Least-squares means

PDS: Post-partum dysgalactia syndrome (PDS+ is cases and PDS÷ is healthy sows)

SD: Standard deviation

TNF- α : tumor necrosis factor α

WBC: white blood cell

Declarations

Ethics approval and consent to participate

The experimental protocol was approved in advance by the Danish Animal Experiments Inspectorate. All procedures were carried out in agreement with the Danish Animal Testing Act and approved by the Danish Animal Experiments Inspectorate. The animals originated from a private owner, who gave his informed consent for the use of the animals for scientific purposes.

Consent for publication

Not applicable.

Competing interests

The authors declare that there are no conflicts of interest.

Funding

The study was funded by Innovation Fund Denmark (IFD) under File No. 1355-00121, the Danish Agriculture & Food Council/SEGES, Copenhagen, Denmark, and the Seneca Foundation of Murcia Region, Spain, with grant number 19849/GERM/15). The study design was approved by SEGES and IFD. SEGES contributed with technical support during data collection and statistical analysis.

Availability of data and materials

The datasets used and analysed during the current study is available from the corresponding author on reasonable request.

Authors' contributions

The study was designed by MK, SJ, MJ, PHA, PB, DE, JJC and FT. Data and samples were collected by MK and MJ. JJC, DE and FT performed laboratory analyses. MK, JD and SJ performed statistical analyses. MK and FT drafted the manuscript. All authors interpreted, read, revised, and approved the final manuscript.

Acknowledgments

The authors thank the staff and the vet at the farm: Jørn Skov Jensen, Anna Bech and Christian Pårup Nielsen for providing access to the barn and helping with practical work; Karen Bach-Mose, Hanne Præstgaard, Jens-Ove Hansen, Peter Nøddebo Hansen, Kristina Nøddebo Balle, Sarah Mortensen, Peter Hansen, Hanne Nissen are thanked for technical work during data collection.
