# Abstract

**Background:** Angiopoietin-Tie2 and nitric oxide pathway is crucial in tumor angiogenesis and closely correlates with tumor development, growth, and metastasis. This study aimed to investigate the angiopoietin-Tie2 and nitric oxide signaling of erythrocyte membrane in response to surgical trauma in head and neck cancer.

**Methods:** We prospectively enrolled the patients with histology-proven head and neck squamous cell carcinoma undergoing surgical resection of primary tumors at the medical center between August and November 2019. We measured the preoperative and postoperative levels of angiopoietin-1, angiopoietin-2 in plasma using enzyme-linked immunosorbent assays, nitric oxide in plasma using nitrate/nitrite colorimetric assays, and Tie2 phosphorylation in erythrocyte membrane using Western blotting.

**Results:** The plasma angiopoietin-1 was down-regulated from median 971.3 pg/mL (interquartile range [IQR]: 532.1 – 1569.3) to 417.9 (IQR: 270.5 – 597.3) after tumor resection ( $p=0.0020$ ). Conversely, the plasma angiopoietin-2 was enhanced from 1173.6 pg/mL (IQR: 977.7 – 1450.2) to 2353.7 (IQR: 1352.4 – 2954.3) after surgery ( $p=0.0021$ ), with a concomitant increase in plasma nitric oxide level from 7.73  $\mu\text{M}$  (IQR: 5.39 – 10.06) to 10.50 (IQR: 7.65 – 14.18) after surgical resection ( $p=0.0093$ ). Subgroup analyses further showed the angiopoietin-Tie2 and nitric oxide signaling was significant only in stage III and IV cancer.

**Conclusions:** The dynamic change of angiopoietin-Tie2 signaling in erythrocyte membrane along with the enhanced nitric oxide in plasma after tumor resection suggests erythrocytes play a significant role in modulating surgery-induced angiogenesis, which may provide a novel marker for cancer surveillance and control.

## Background

Over 500,000 new cases of head and neck squamous cell carcinoma (HNSCC) were diagnosed worldwide each year, and two thirds of them occurred in industrialized countries.<sup>1</sup> In HNSCC, carcinogenesis is a two-step process featured by an initial precancerous lesion and the malignant transformation characterized by angiogenic switch with an increase in neovascularization.<sup>2</sup>

Angiogenesis, the process through which new blood vessels form from pre-existing vessels, is a critical element of tumor growth and metastasis in HNSCC as in other solid tumors.<sup>3</sup> The angiopoietin-Tie2 signaling pathway is crucial in regulating tumor angiogenesis and closely linked to the development, progression, and metastasis of cancer cells.<sup>4-6</sup> The regulation of the cytokines angiopoietin-1 and angiopoietin-2 functions in angiogenesis and vascular remodeling through their interaction with the vascular receptor tyrosine kinase Tie2.<sup>7</sup> Previous studies have showed that expression of angiopoietin-2 was significantly associated with angiogenesis and vessel maturation in oral squamous cell carcinoma

(SCC).<sup>6</sup> Animal study reported that overexpression of angiopoietin-2 has also been shown to promote the growth and metastasis of oral SCC.<sup>8</sup> Besides, experimental study demonstrated the distinct expressions of angiopoietin-1 and angiopoietin-2 in tumor samples of human oral SCC.<sup>9</sup> However, the dynamic changes of these angiogenic factors in the setting of tumor resection remains unclear.

Nitric oxide (NO) is essential in various physiological as well as pathological processes. In recent decades, NO was demonstrated to regulate different cancer-related events including angiogenesis, progression, and metastasis.<sup>10</sup> NO may induce and promote tumor angiogenesis through the mechanism of vessel dilatation by endothelial NO synthase (eNOS), release of vascular endothelial growth factor (VEGF), and increased production of prostaglandin E2 inducing tumor vasculature hyperpermeability.<sup>10</sup>

Although surgical resection is potential curative for patients with HNSCC tumors, surgical injury may trigger the release of proangiogenic factors and facilitate the growth and spread of residual cancer cells.<sup>1,11</sup> Prior studies have showed that plasma levels of angiopoietin-2 and VEGF were increased after surgical resection of primary tumors in lung, breast, and colorectal cancer.<sup>11,12</sup> However, the angiopoietin-Tie2 and NO signaling in response to surgical injury remains unclear in HNSCC.

Erythrocytes act as an important interorgan communication network in controlling systemic NO metabolism and tissue oxygen transport.<sup>13</sup> Our previous study showed the hypo-osmotic stimulus enhances angiopoietin-1 secretion in plasma through the Tie2/Akt/eNOS signaling pathway in erythrocytes.<sup>14</sup> However, the role of erythrocytes in cancer angiogenesis has not been clarified yet.

Based on the above background, this study aimed to evaluate the angiopoietin-Tie2 and NO signaling in erythrocyte membrane in response to surgical treatments of HNSCC. Specifically, we conducted this study by measuring the dynamic changes in plasma angiopoietin-1, angiopoietin-2 and NO levels and determined the phosphorylation level of tyrosine kinase receptor Tie2 in erythrocyte membrane before and after surgical resection of HNSCC.

## Methods

### *Clinical setting and patient enrollment*

We enrolled the patients with histology-proven HNSCC undergoing surgical resection of primary tumors with or without node dissection and flap reconstruction at the medical center between August and November 2019. Exclusion criteria were age below 20 years, any history of erythrocyte disorder (e.g. sickle cell disease, glucose-6-phosphate dehydrogenase deficiency), uses of exogenous NO provider (e.g. glycerin trinitrate or sodium nitroprusside), prior surgery for malignancy or other pathologies in head and neck region, recurrent diseases of HNSCC, and patient refusal to participate. After meeting the selection

criteria, a total of 14 patients with HNSCC were enrolled. In order to compare the baseline levels of angiopoietin-Tie2 and NO signaling, we included 14 volunteers without any history of malignancy, who were regarded as non-cancer controls.

### ***Study outcomes***

Primary outcome of this study was the plasma concentrations of angiopoietin-1 and angiopoietin-2 measured before and after surgical resection. Secondary outcomes comprised the plasma levels of NO and the tyrosine phosphorylation level of Tie2 in erythrocyte membrane.

### ***Collection of covariates***

We collected the data of patient characteristics, including demographics, American Society of Anesthesiologists class, and habits of tobacco smoking, alcohol intake, and betelnut chewing.<sup>15,16</sup> Clinical covariates included types of surgical procedures, anesthesia time, intraoperative blood loss, and intraoperative uses of blood transfusion.<sup>17,18</sup> Pathology features were differentiation grade, angiolymphatic invasion, and perineural invasion.<sup>19,20</sup> Tumor nodes metastasis (TNM) staging was translated into stages I to IV according to the American Joint Committee on Cancer (AJCC) criteria, seventh edition.<sup>21</sup>

### ***Blood sample collection***

Peripheral blood was sampled through radial arterial catheters before surgical incision (baseline) and at the end of surgery. Blood samples were stored in K2 ethylenediaminetetraacetic acid (EDTA)-containing tubes (Becton Dickinson, NJ, USA) for plasma and protein extraction. Plasma was centrifuged at 3000 rpm for 10 min without brake and then stored at -80°C. Erythrocytes were isolated by Ficoll Paque Plus (GE Healthcare Bio-Sciences AB, Uppsala, Sweden). Equal amounts of erythrocytes were added in three volume times of ice cold 1 mM Na<sub>2</sub>HPO<sub>4</sub>, 1 mM EDTA, 1 mM phenylmethylsulfonyl fluoride (PMSF, Gold Biotechnology, St. Louis, MO, USA), and pH 7.4 wash buffer. Erythrocyte membrane was washed to eliminate hemoglobin by pelleting at 14,500 rpm for 20 min at 4°C for over four wash cycles and then also stored at -80°C for further processing.

### ***Nitric oxide detection***

NO concentration in plasma was measured by determining its stable end products, nitrite and nitrate.<sup>22</sup> Plasma nitrite and nitrate were measured by the nitrate/nitrite colorimetric assay kit (Cayman Chemical®, MI, USA). The first step was conversion of nitrate to nitrite using nitrate reductase. The second step was addition of the Griess reagents. After 10 min of incubation at room temperature, the absorbance is measured at 550 nm wavelength with a microplate reader (BioTek Instruments, VT, USA).

### ***Angiopoietin-1 and angiopoietin-2 expression***

To detect the levels of angiotensin-1 and angiotensin-2 in plasma, enzyme-linked immunosorbent assay (ELISA) kits were used and carried out according to the manufacturer's protocol (DANG10 and DANG20, R&D, MN, USA). Briefly, standards of angiotensin-1 and angiotensin-2 were prepared, and 1:5 diluted plasma samples were pipetted into wells with specific monoclonal antibody pre-coated microplate. After washing away unbound solution, enzyme-linked monoclonal antibodies were added to wells. Following a wash to remove any unbound antibody-enzyme solutions, substrate solution was added to wells and color developed in proportion to the control or sample concentrations. Finally, tetramethylbenzidine solution was added to stop the reaction. We detected the intensity of the reaction color at 450 nm wavelength with a microplate reader (BioTek Instruments, VT, USA). All measurements were performed in duplicate.

### ***Immunoprecipitation for Western blotting***

The level of Tie2 tyrosine phosphorylation was detected by an immunoprecipitation assay. The method for Tie2 tyrosine phosphorylation immunoprecipitation was described in the authors' previous articles.<sup>14,23</sup> Specific antibody for detecting total Tie2 was purchased from Abcam (Abcam, Cambridge, UK). b-actin was purchased from SantaCruz (Santa Cruz Biotechnology, TX, USA). Specific bands from an immunoblotting reaction were visualized using the Enhanced Chemiluminescence System (Millipore, MA, USA). The intensity of each band was analyzed using the ImageJ software (National Institutes of Health, Bethesda, MD, USA).

### ***Statistical analysis***

A sample size of 14 was estimated to have 80% power to detect an effect size of 80% change in angiotensin-1 or angiotensin-2 levels in plasma for paired difference comparisons with a 2-sided significance level of 0.05.<sup>24</sup> Shapiro-Wilk test and Kolmogorov-Smirnov test were used as normality tests. Normally distributed variables were presented as mean with standard deviation (SD). Non-normally distributed data were presented as median with interquartile range [IQR] and range. Independent t test or Mann-Whitney U test was used to compare cancer patients and non-cancer controls in outcome variables before surgery, as appropriate. Paired sample t test or Wilcoxon signed rank test was used to determine the statistical difference in changes of angiotensin-1, angiotensin-2, and NO levels in plasma and Tie2 phosphorylation levels before and after surgery in the cancer patients, as appropriate. The significance level of all hypotheses was 0.05 for a two-sided test. Statistical analyses were conducted using SAS software, version 9.4 (SAS Institute Inc., Cary, NC, USA) and presenting graph with Prism version 5.0 (GraphPad software, San Diego, CA, USA).

## **Results**

Table 1 showed the demographic data, cancer characteristics, and type of surgical procedures of the cancer patients. In cancer characteristics, 7 out of the 14 cancer patients had stage IV diseases. Besides, 7 and 9 patients had the histology diagnosis of angiolymphatic invasion and perineural invasion,

respectively. Regarding the surgical procedures, 12 patients underwent neck dissection for the removal of lymph nodes and surrounding tissue from the neck, and 12 patients underwent flap reconstruction. Table 2 showed the intraoperative hemodynamic and biochemical parameters. The anesthesia time was mean  $790 \pm \text{SD } 285$  min. Intraoperative blood loss was  $500 \pm 366$  mL, and 6 patients needed intraoperative transfusions of blood.

### ***Baseline levels of plasma angiotensin-1 and angiotensin-2***

The plasma level of angiotensin-1 was significantly higher in cancer patients compared to controls, median 671.4 pg/mL (IQR: 440.9 – 1035.9, range: 359.1 – 2490.4) vs. 288.9 (IQR: 189.8 – 389.6, range: 98.4 – 492.9) (Mann-Whitney U test:  $p=0.0028$ ; Shapiro-Wilk test:  $p<0.0001$ , Kolmogorov-Smirnov test:  $p<0.0100$ ). The plasma level of angiotensin-2 was lower in cancer patients compared to controls, median 1362.9 pg/mL (IQR: 1223.1 – 1707.7, range: 750.4 – 2054.2) vs. 1868.5 (IQR: 1531.0 – 2338.4, range: 1248.7 – 5489.9) (Mann-Whitney U test:  $p=0.0257$ ; Shapiro-Wilk test:  $p<0.0001$ , Kolmogorov-Smirnov test:  $p<0.0100$ ).

### ***Baseline level of Tie2 tyrosine phosphorylation in erythrocyte membrane***

The intensity ratio of phospho-Tie2/Tie2/ $\beta$ -actin in erythrocyte membrane was significantly higher in cancer patients compared to controls, mean  $5.18 \pm \text{SD } 0.92$  vs.  $3.55 \pm 0.68$  (independent t test:  $p=0.0003$ ; Shapiro-Wilk test:  $p=0.8392$ , Kolmogorov-Smirnov test:  $p>0.1500$ ). (Figure 1)

### ***Baseline level of plasma nitric oxide***

The plasma NO level of cancer patients was significantly higher than non-cancer controls, median 4.95  $\mu\text{M}$  (IQR: 2.70 – 11.90, range: 1.30 – 19.00) vs. 1.42 (IQR: 1.13 – 2.75, range: 0.64 – 5.69) (Mann-Whitney U test:  $p=0.0022$ ; Shapiro-Wilk test:  $p<0.0001$ , Kolmogorov-Smirnov test:  $p<0.0100$ ).

### ***Dynamic change of plasma angiotensin-1 and angiotensin-2 during surgery***

The plasma level of angiotensin-1 was down-regulated from median 971.3 pg/mL (IQR: 532.1 – 1569.3, range: 303.7 – 2400.7) to 417.9 (IQR: 270.5 – 597.3, range: 176.0 – 839.1) after tumor resection [change: mean -638.8, 95% confidence interval (CI): -989.3 – -288.3; paired sample t test:  $p=0.0020$ ; Shapiro-Wilk test:  $p=0.1301$ , Kolmogorov-Smirnov test:  $p>0.1500$ ]. Conversely, the plasma level of angiotensin-2 was significantly upregulated from median 1173.6 pg/mL (IQR: 977.7 – 1450.2, range: 813.7 – 1802.1) to 2353.7 (IQR: 1352.4 – 2954.3, range: 791.1 – 3653.4) after surgery (change: 970.2, 95% CI: 435.3 – 1505.0; paired sample t test:  $p=0.0021$ ; Shapiro-Wilk test:  $p=0.9899$ , Kolmogorov-Smirnov test:  $p>0.1500$ ). (Figure 2A)

Subgroup analyses showed the baseline level of plasma angiotensin-1 was median 736.6 pg/mL (IQR: 496.5 – 1177.7, range: 303.7 – 1839.7) in stage III and IV cancer and 1299.0 pg/mL (IQR: 1224.2 – 1844.0, range: 402.4 – 2400.7) in stage I and II cancer (Mann-Whitney U test:  $p=0.1439$ ). The baseline level of plasma angiotensin-2 was median 1261.8 pg/mL (IQR: 1018.6 – 1579.6, range: 967.5 – 1802.1)

in stage III and IV cancer and 987.9 pg/mL (IQR: 883.9 – 1303.8, range: 813.7 – 1499.1) in stage I and II cancer (Mann-Whitney U test:  $p=0.2556$ ). The decrease in angiopoietin-1 and increase in angiopoietin-2 after surgery were significant only in stage III and IV diseases [change of angiopoietin-1: mean -430.8 (95% CI: -750.3 – -111.3,  $p=0.0164$ ) in stage III and IV and -903.0 (95% CI: -2165.9 – 359.9,  $p=0.1074$ ) in stage I and II; change of angiopoietin-2: 1456.5 (95% CI: 832.3 – 2080.7,  $p=0.0012$ ) in stage III and IV and 320.2 (95% CI: -628.9 – 1269.4,  $p=0.3616$ ) in stage I and II]. (Figure 2B)

### ***Dynamic change of Tie2 tyrosine phosphorylation during surgery***

The level of Tie2 tyrosine phosphorylation in erythrocyte membrane was significantly decreased in cancer patients after surgery with a relative change  $-23.2 \pm 21.2\%$  (paired sample t test:  $p=0.0072$ ; Shapiro-Wilk test:  $p=0.5501$ , Kolmogorov-Smirnov test:  $p>0.1500$ ). (Figure 3)

### ***Dynamic change of plasma nitric oxide during surgery***

The level of plasma NO was significantly enhanced from median 7.73  $\mu\text{M}$  (IQR: 5.39 – 10.06, range: 1.84 – 18.58) to 10.50 (IQR: 7.65 – 14.18, range: 2.49 – 33.11) after surgical resection (Wilcoxon signed rank test:  $p=0.0093$ ; Shapiro-Wilk test:  $p=0.0009$ , Kolmogorov-Smirnov test:  $p<0.0100$ ).

The baseline level of plasma NO was median 9.45  $\mu\text{M}$  (IQR: 7.19 – 12.39, range: 4.66 – 18.58) in stage III and IV cancer and 6.11  $\mu\text{M}$  (IQR: 2.29 – 6.46, range: 1.84 – 8.81) in stage I and II cancer (Mann-Whitney U test:  $p=0.0513$ ). Similarly, subgroup analyses showed the enhancement of plasma NO was significant only in stage III and IV diseases [median 9.45 (IQR: 7.19 – 12.39) to 14.09 (9.96 – 25.52), Wilcoxon signed rank test:  $p=0.0156$  in stage III and IV; 6.11 (2.29 – 6.46) to 7.03 (3.42 – 10.27), Wilcoxon signed rank test:  $p=0.1875$  in stage I and II].

## **Discussion**

In this study, we found that surgical resection of the HNSCC tumors down-regulated the plasma angiopoietin-1 level and up-regulated the plasma angiopoietin-2 in conjunction with an increase in plasma NO level and reduced phosphorylation level of Tie2 in erythrocyte membrane. Importantly, the angiogenic and NO signaling was significant only in stage III and IV HNSCC. The dynamic change of angiopoietin-Tie2 and NO signaling in erythrocyte membrane in response to surgical trauma suggests that erythrocytes have an important role in modulating surgery-induced angiogenesis, which may provide an important implication for cancer surveillance and control.

Previous studies showed that surgical injury increases the plasma levels of angiopoietin-2 and VEGF in lung, breast, and colorectal cancer.<sup>11,12</sup> Our results further showed the plasma angiopoietin-2 was also upregulated by surgery in HNSCC. Angiopoietin-1 and angiopoietin-2 are two important cytokines and function with the vascular Tie2 receptor in regulating the complex process of angiogenesis.<sup>25,26</sup> Accumulating evidences have demonstrated that like angiopoietin-1, angiopoietin-2 can induce the phosphorylation of Tie2 receptor and promote chemotaxis, tube formation, and sprouting of endothelial

cells.<sup>27,28</sup> The expression of angiopoietin-2 is upregulated at sites of tumor angiogenesis in multiple types of cancer, and overexpression of angiopoietin-2 promoted angiogenesis and tumor growth in experimental models.<sup>8,29,30</sup> Importantly, overexpression of angiopoietin 2 accelerated the carcinogenesis of oral squamous cell carcinoma through promoting epithelial-mesenchymal transition-induced angiogenesis.<sup>8</sup> Angiopoietin-2 has been proposed as a potential target for antiangiogenic drug development.<sup>31</sup> In our study, the increased angiopoietin 2 in plasma after surgery suggests that surgical injury may trigger the release of proangiogenic factors and facilitate the proliferation and metastasis of residual tumor cells in HNSCC.<sup>1,11</sup> These results provided important evidence for identifying patients with high risk of cancer relapse and establishing individualized anti-cancer therapy after surgical resection. However, current practice about surgical resection of primary tumors in HNSCC should not be changed until more evidence is gained to clarify the clinical impact of this angiogenic response on cancer prognosis.

The discrepancies of angiogenic expression in tumor cells between angiopoietin-1 and angiopoietin-2 have been reported in multiple types of cancer, including oral cancer<sup>9</sup>, gastric cancer<sup>32</sup>, and colon cancer<sup>33</sup>. Study has shown that compared with healthy oral mucosa, angiopoietin-2 is overexpressed and angiopoietin-1 is down-regulated in tumor samples of oral squamous cell carcinoma.<sup>9</sup> We proposed that the distinct response to surgery between angiopoietin-1 and angiopoietin-2 in our study may be explained by the mechanism that surgical manipulation of tumors induces the opposite regulation of angiopoietin-1 and angiopoietin-2 in the setting of surgical trauma.

Our results showed patients with HNSCC have a higher plasma level of NO before surgery compared to non-cancer controls. Besides, the raised plasma NO level in cancer patients was further enhanced after surgical resection of tumors. Study has showed that NO production induced by ethanol and tobacco may initiate inflammatory response, dysregulate antioxidant protection system, and contribute to tumor growth in head and neck cancer.<sup>34,35</sup> Investigators have showed surgical trauma stimulates the release of angiopoietin-2 and VEGF in plasma and promotes the process of angiogenesis in lung, breast, and colorectal cancer.<sup>11,12</sup> Our results further suggested a novel mechanism of surgery-induced angiogenesis via NO signaling pathway. NO has been shown to regulate the process of angiogenesis and promote tumor progression through the mechanism of vessel dilatation by eNOS, release of VEGF, activation of cyclooxygenase-2 stimulating the production of proangiogenic factors, and increased production of prostaglandin E2 inducing tumor vasculature hyperpermeability.<sup>10</sup> NO may also have clinical significance as a biomarker of inflammation and risk stratification of malignant transformation in patients with oral pre-cancer.<sup>10</sup> Researchers have proposed NO as a novel potential therapeutic target in resistant cancer by sensitizing cancer cells to chemotherapy and immunotherapy.<sup>36</sup> However, further studies are needed to evaluate the therapeutic applications of NO in cancer.

In this study, we found the baseline phosphorylation level of Tie2 in erythrocyte membrane was significantly higher in cancer patients compared with non-cancer controls and was correspondingly reduced after surgery in connection with the decreased angiopoietin-1 level and increased angiopoietin-2

level in plasma. Tie2 is a receptor tyrosine kinase expressed principally on vascular endothelium and interacts with its ligand angiopoietin-1 and angiopoietin-2 in regulating vessel branching and maintaining endothelial homeostasis.<sup>37</sup> Experimental study recently demonstrated that an *in-vitro* treatment with angiopoietin-1 for Tie2-overexpressed oral squamous cell carcinoma cells enhances the cell-cell and cell-extracellular matrix adhesive activities of cancer cells.<sup>38</sup> This finding indicates that angiopoietin-1 directly up-regulates the functional activity of Tie2. In our study, the angiopoietin-1 plasma level was decreased after surgical resection, which may subsequently suppress the tyrosine phosphorylation level of Tie2 in erythrocyte membrane. Our prior study has showed that osmopressor response activates the Tie2/Akt/eNOS signaling pathway in erythrocytes and stimulates the secretion of angiopoietin-1 in plasma.<sup>14</sup> The present study further demonstrated surgical injury activates the angiopoietin-Tie2 and NO signaling axis in erythrocyte membrane, indicating that peripheral erythrocytes may serve as a potential diagnostic and therapeutic target for cancer patients.

There are limitations to our study. First, our findings should be interpreted with caution due to small patient sample. Second, we did not measure the long-term risk of cancer recurrence and mortality after surgical resection and therefore could not evaluate the relationship between our biological findings and clinical outcomes. Third, more studies are need to clarify how Tie2/Akt/eNOS signaling pathway interacts between vascular beds and erythrocytes in surgical injury. Fourth, we did not measure the long-term change of angiogenic response (e.g. 30 days after surgery), which is important for postoperative adjuvant therapy.<sup>29</sup> Finally, we did not measure the postoperative changes of angiogenic factors in non-cancer controls; therefore, whether our results are applicable to surgical patients without cancer is unclear.

In conclusion, the dynamic change of angiopoietin-Tie2 and NO signaling in erythrocyte membrane in response to surgical resection of HNSCC suggests that erythrocytes have a significant role in modulating surgery-induced angiogenesis, which may provide a novel marker for cancer surveillance and control. We need more studies to evaluate the relationship between changes in angiopoietin-Tie2 and NO expression on cancer outcomes after tumor resection and to explore potential clinical applications of angiopoietin-Tie2 and NO signaling in cancer prevention and treatment.

## Abbreviations

AJCC: American Joint Committee on Cancer

EDTA: ethylenediaminetetraacetic acid

eNOS: endothelial NO synthase

HNSCC: head and neck squamous cell carcinoma

IQR: interquartile range

NO: Nitric oxide

PMSF: phenylmethylsulfonyl fluoride

SCC: squamous cell carcinoma

SD: standard deviation

TNM: Tumor nodes metastasis

VEGF: vascular endothelial growth factor

## Declarations

**Ethics approval and consent to participate:** We obtained the approval from the research ethics committee of Taipei Veterans General Hospital in Taiwan (IRB-TPEVGH No. 2018-06-015AC) and conducted in accordance with the institutional ethical standards of the responsible committee on human experimentation. Informed consent was obtained from each subject.

**Consent for publication:** Not applicable

**Availability of data and materials:** The datasets used and/or analysed during the current study are available from the corresponding author on reasonable request.

**Competing interests:** The authors declare that they have no competing interests.

**Funding:** This work was supported by the grants from Taipei Veterans General Hospital (V108C-001), Taipei, Taiwan and Ministry of Science and Technology (MOST 106-2314-B-075-015-MY3), Taipei, Taiwan.

**Author Contributions:** HLW contributed to data acquisition and manuscript writing. YHC contributed to experiment conduction and statistical analysis. YHT contributed to statistical consultation and review. CHW, WLL and SKT helped in subject enrollment. MYT and CCY contributed to manuscript revision. CCL contributed to manuscript revision and gave final approval of the version to be published and agreed to be accountable for ensuring the accuracy or integrity of the work. All authors read and approved the final manuscript.

**Acknowledgements:** We are deeply indebted to the staff of Department of Stomatology and Department of Otolaryngology, Taipei Veterans General Hospital for their assistance and support in this research.

## Figures

**(A)**

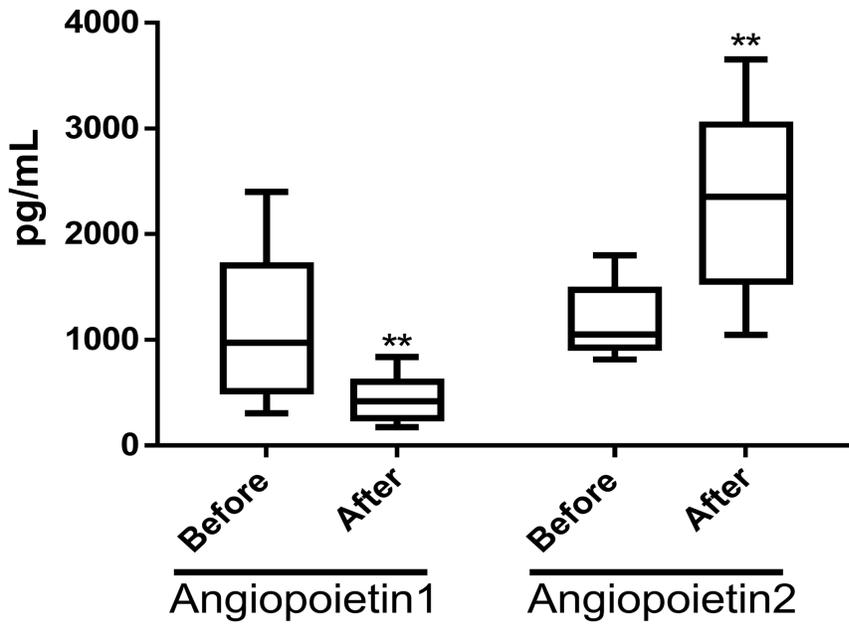

**(B)**

**Figure 1**

Tie2 tyrosine phosphorylation assay in erythrocyte membrane. (A) A representative gel was shown. (B) Semi-quantitative analysis with ratio of the intensity of phospho-Tie2 receptor protein relative to total Tie2 receptor protein and  $\beta$ -actin indicated.  $n = 10$ , \*\*\* $p < 0.001$ .

(A)

(B)

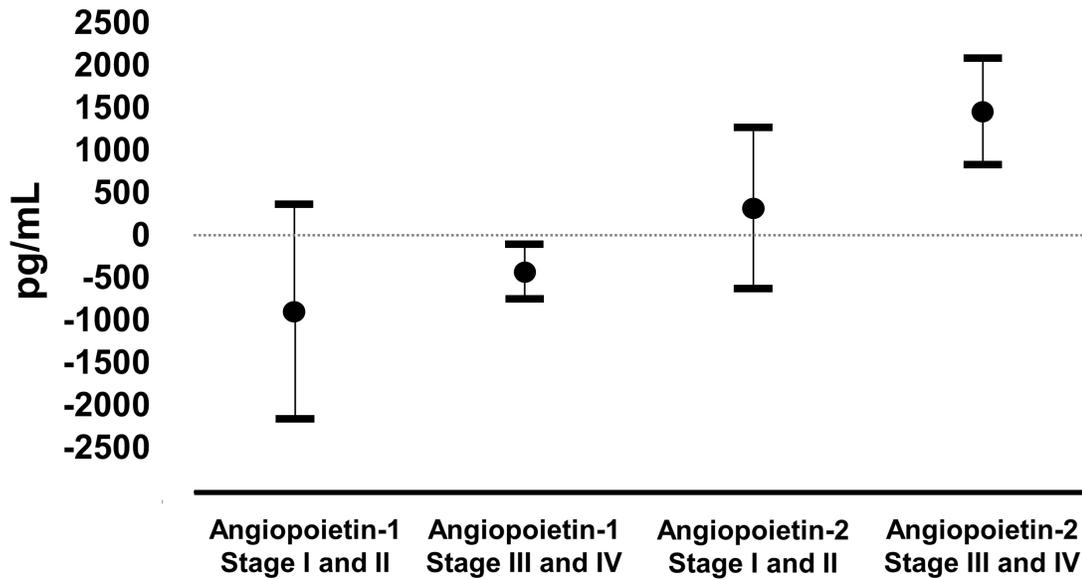

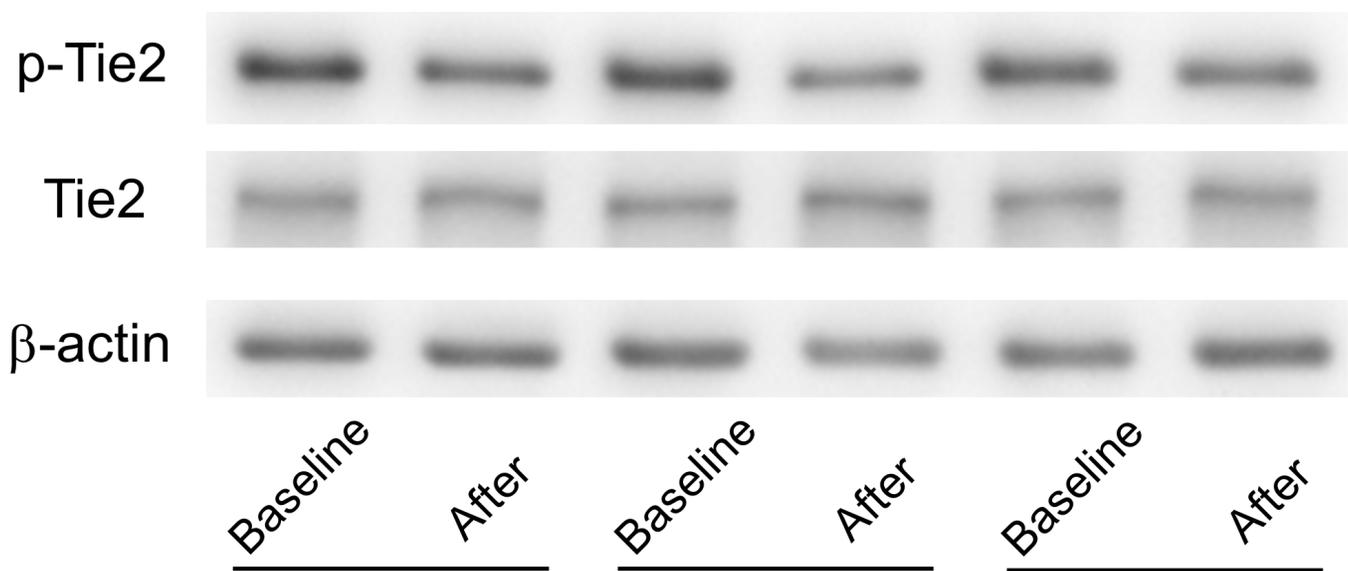

Figure 2

(A) Angiopoietin-1 and angiopoietin-2 plasma levels before and after surgery in cancer patients; (B) Change in angiopoietin-1 and angiopoietin-2 levels, mean and 95% confidence interval. n = 10, \*\*p < 0.01.

(A)

(B)

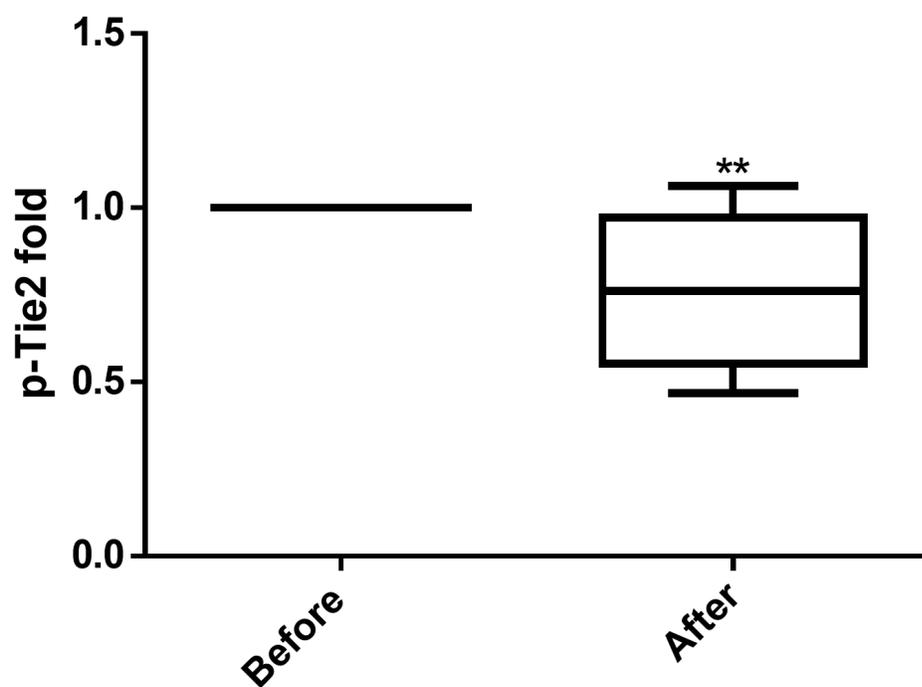

Figure 3

Comparisons of Tie2 phosphorylation levels in erythrocyte membrane before and after surgery in cancer patients. (A) A representative gel was shown. (B) Intensity ratio of Tie2 receptor protein tyrosine phosphorylation relative to total Tie2 receptor protein. Tie2 tyrosine phosphorylation level was significantly downregulated after surgery in cancer patients.  $n = 10$ ,  $**p < 0.01$ .
