Abstract

In this paper, a new scheme based on permutation index-differential chaos shift keying is proposed, modeled, and evaluated in AWGN channel environment. Data is sent by frames, each frame is headed by a single reference signal and followed by some information bearing signals. Modulation is performed through permutations of a reference signal according to the mapped data. At the receiver, each incoming information bearing signal undergoes all inverse permutation possibilities to perform a correlation with the delayed and stored version of the received reference signal. To decode the information bits, the detector selects the highest correlator outputs. The proposed scheme named Single Reference-Permutation Index-Differential Chaos Shift Keying (SR-PI-DCSK) is an enhanced version of PI-DCSK, and uses a single reference signal for multiple information bearing ones. Hence, the energy requirement is saved by almost a half. The bit error performance is studied using the baseband system model and analytically tested using Gaussian Approximation (GA) method. Results show the BER performance outperforms other standard and recently developed differentially coherent chaos systems, including Permutation Index-DCSK by an average of 2.25 db. Moreover, the analytical form which is developed to predict the Bit Error Rate (BER) is validated by simulation. Results demonstrate the performance in AWGN is closely matching with the simulation results, particularly at high SNR.

Keywords: Differential Coherence; AWGN Channel; Differential Correlator; Permutation Index

1 Introduction

Chaotic communication systems are broadly classified into coherent, non-coherent and differentially coherent systems [?][?]. Implementation of coherent systems requires an accurate generation of the chaotic segment at the receiver which is identical to the transmitted one. Due to noise contribution, the received signal becomes distorted and difficult to synchronize. Theoretical implementation of coherent Chaos Shift Keying (CSK) is proposed in [?]. Additionally, the maximum likelihood detection scheme is used in [?] to enhance Bit-Error-Rate (BER) performance for multiple users. Changing of Probability Density Function (PDF) for the chaotic source to match PDF of the channel to enhance BER is simulated and discussed in [?]. All the previous coherent systems require an accurate regeneration of the chaotic segment at the receiver which is difficult to achieve due to the chaotic nature of the source and the channel noise. The work in [?][?] consider demodulation

in non-coherent systems based on the received signal properties (i.e. bit energy, map estimation, or time reversing). These systems require an effective extracting of the transmitted signal and precise threshold optimization between signal elements. In all differential chaos based scheme, data symbols is presenting by sending the reference signal followed by information bearing as in DCSK. At the receiver, correlation is performed by multiplying the incoming information bearing signal with the delayed version of the reference signal. In Correlation Delay Shift Keying (CDSK), the transmitted signal consists of the current information signal added to the reference signal of the previous symbol as discussed in [?][?][?][?]. However, the proposed schemes are complex and require additional synchronization circuits. In DCSK, the reference signal and information bearing signal are sent through consecutive time slots. Therefore, a frequency delay line is required at the receiver. Radio Frequency (RF) delay line removal to reduce systems complexity in DCSK receiver is suggested in [?] and developed in [?]. The removal is done by sending the reference signal and the information bearing signal on the same time slot and separate them using Walsh code. Here, more delay elements are added to the transmitter in addition to the usage of lengthy Walsh code. Reference and information signal separation using initial condition modulation is examined in [?]. Efficient utilization of the transmitted signal energy using Multicarrier Modulation for DCSK (MC-DCSK) is introduced in [?]. However, a hardware implementation requires a bank of narrow-band modulators with a high degree of accuracy in the design to maintain subcarrier synchronization. The work in [?] uses Space-Time Block Code DCSK (STBC-DCSK) to enhance BER performance. Although STBC-DCSK enhances the noise performance of DCSK, the data rate and the average energy for each bit are similar to that in DCSK with an additional STBC encoder at the transmitter.

Permutation index DCSK is used to build the first MARY modulation scheme in [?][?], an advanced version of the PI-DCSK is proposed on [?]. Improved versions of PI-DCSK where reference chaotic segment and information bearing signal are combined on one-bit duration are presented in [?]. Walsh Code is also recalled in [?] to separate reference and information bearing signal. While the dual used mode of the reference signal is being suggested in [?]. In all the previous literature, DCSK is based on having one to one relationship between the reference signal and information bearing signal. In this brief, a common reference signal is used to modulate multiple information bits respective by signal permutation according to the information bits, hence the proposed system enhances the energy efficiency by almost 50%. Also, it offers double bit rates compared to standard chaos-based systems namely DCSK, Correlation Delay Shift Keying, High Efficiency-DCSK (HE-DCSK), and Time Reversal-DCSK(TR-DCSK).

The main contribution of this paper as follows: we develop an SR-PI-DCSK which uses a single reference signal for multiple information bearing ones. we compare BER performance with the other differentially and permutation based DCSK that uses a dedicated reference signal for each information symbol. The developed model is mathematically analyzed and verified by simulation under various factors and different channel conditions.

The remainder of this paper is organized as follows. Section 2 and Section 3 present the transmitted signal frame and scheme for the proposed SR-PI-DCSK system,

respectively. The details of system analysis are discussed in Section 4 and Section 5. The details of experimental results with discussion are provided in Section 6. Finally, Section 7 concludes the paper.

2 System Signal Format

The transmitted signal frame of SR-PI-DCSK is shown in Fig. 1. Each frame consists of a reference signal segment with a length of β samples followed by L information bearing signals. Information bearing signal is nothing but only a permuted version of the reference signal. Permutation order is determined by the information bits with the length of n , for example, to send 2 information bits, we need to set up 2^2 permutations from the reference signal while 3 bits requires 9 different permutations.

3 The Proposed Scheme

To generate the signal in Fig. 1, the design of modulator and demodulator of SR-PI-DCSK system are shown in Fig. 2 and Fig. 3, respectively. A reference signal X is generated with the chaotic samples having a length of β . This reference signal is sent initially prior to the frame through switch S, to modulate the first information symbol, the same version of the reference signal is delayed and undergoes permutation operation according to the transmitted bits. The reference signal and its permuted version are related in a way that ensures very low correlation such that $XP_j^T(X) = 0$ [?], where $P_j(\cdot)$ is the permutation operator. A chaotic signal with the spreading factor of β can be permuted in $\beta! - 1$ permutation. Hence for information bits vector $a = (a_1 \ a_2 \ \dots \ a_n)$ with length of n , we will select one distinguished permutation out of $\beta! - 1$ and to have permutation mapping such away that $a_j \rightarrow P_j$ and $P_j \in \{P_1 \ P_2 \ \dots \ P_{2^n}\}$. Furthermore, P_j is the permutation performed in the chaotic sequence to present a_j data set. Thus, the first transmitted frame can be given by the baseband representation as:

$$S = \left[\underbrace{X_0}_{\text{reference}} \quad \underbrace{P_{j1}X_\beta^T}_{\text{1st symbol}} \quad \underbrace{P_{j2}X_{2\beta}^T}_{\text{2nd symbol}} \quad \dots \quad \underbrace{P_{jL}X_{L\beta}^T}_{\text{Lth Symbol}} \right] \quad (1)$$

Where $X_0 = (x_1 \ x_2 \ \dots \ x_\beta)$ is the reference chaotic segment and $P_{j1}X_\beta^T$ represents the first information signal which is nothing but reference signal delayed by β and permuted by P_{j1} mapped from information vector a_{j1} . Moreover, L is the frame length. In this paper, the analysis is simplified using the analysis of the first symbol only, similar methods can be applied on other following information symbols since all the symbols are statistically independent.

Under the assumption that the transmitted signal is received via AWGN channel and the transmitter and receiver are perfectly synchronized. The following operations are performed in the receiver: (i) the first incoming reference signal, is loaded into delay block and stored for correlation with other L symbol as shown in Fig. 2. (ii) the following information bearing signal is directly loaded to the permutation block to perform all possible M inverse permutations, where $M = 2^n$.

To detect the first information symbol, the received reference signal is delayed by β , (i.e $X_\beta + W_\beta$) is correlated with output of m^{th} inverse permutation block output

where $m \in (1, 2, \dots, M)$, hence, the output can be written as $P_m^{-1}(P_{j_1}X_\beta + W_0)$ where $W_0 = (w_1 \ w_2 \ \dots w_\beta)$ is the noise vector and w_k is AWGN noise sample having power spectral density of $N_0/2$. Therefore, the m^{th} correlator output can be found as

$$\begin{aligned} D_m &= (X_\beta + W_\beta)P_m^{-1}(P_{j_1}X_\beta + W_0) \\ &= \underbrace{X_\beta P_m^{-1}P_{j_1}X_\beta^T}_{SS \text{ or } SI} + \underbrace{X_\beta W_0^T + W_\beta P_m^{-1}P_{j_1}X_\beta^T}_{SN} + \underbrace{W_\beta P_m^{-1}W_0^T}_{NN} \end{aligned} \quad (2)$$

Where SS represents desired signal component at $m = j_1$, while SI is the inter signal interference components at $m \neq j_1$. Inter signal interference results from the correlation between the chaotic signal and its permuted version. The NN is the noise to noise correlation that has a significant impact on the performance particularly at a large spreading factor of β .

The first estimated permutation index $\hat{j}_1$ is determined by correlator which is having the maximum output compared with the others, hence

$$\hat{j}_1 = \arg \max \{D_m\}, m \in \{1, 2, \dots, 2^n\} \quad (3)$$

By estimating the correct $\hat{j}_1$, the transmitter can predict which permutation which has been used to send the information.

4 System Analysis

The BER performance analysis is performed analytically using GA methods that are suitable for a system having large spreading factors, However, for low spreading factors, an accurate integration method is suggested [?].

For each L symbols sent, one reference signal is dedicated, therefore, $LE_{symbol} = (L+1)E_s$, where E_{symbol} is the average symbol energy while E_s is average segment energy given by $\beta V(X)$ and $V(.)$ is the variance operator. For standard DCSK and CDSK and standard scheme [?][?][?][?], each information bearing signal is accompanied by reference signal. Therefore to send L symbols, we need to have L additional reference signal, hence energy and bandwidth efficiency are almost doubled. Compared with the proposed scheme, and for sufficient value of L , the energy efficiency can be calculated as

$$E_{\text{efficiency}} = \frac{L+1}{2L} \approx 50\% \text{ for sufficient value of } L \quad (4)$$

Since each symbol is carrying n bits, hence average bit energy is given by

$$LE_{symbol} = LnE_b \quad (5)$$

$$\frac{(L+1)}{Ln} \beta V(X) = E_b \quad (6)$$

5 Performance analysis

In this section, the performance analysis of the proposed scheme is analyzed in AWGN channel environment to predict the BER performance. The chaotic sequence is generated from the symmetric Tent map, given by the equation $x_{k+1} = 1 - 2|x_k|$. The chaotic sequence x is having uniform distribution between -1 and 1 with zero mean and computed variance $V(x) = 1/3$ and $V(x^2) = 4/45 = 4/5V^2(x)$ [?]. For the rest of the analysis, the following assumptions are considered (i) The correlation between the chaotic sequence and its permuted version is decaying quickly for a sufficient correlation window. (ii) The correlation between the chaotic sequence and the noise sample is statistically independent.

The Bit Error Probability of the proposed scheme is determined by calculating (i) errorness of permutation estimation Pr_{map} , (ii) errorness probability of bits detection which largely depends on the number of bits n which calculated by the following

$$P_{r_{map}} = \frac{2^{(n-1)}}{2^n - 1} P_{red} \quad (7)$$

Correct estimation of the transmitted sequence is done by selecting the maximum absolute value of one of the correlator outputs. This output results from the correlation between the delayed reference signal and inverse permuted information bearing signal. Each correlator output can be modeled as a Gaussian random variable D_m . For equiprobable transmitted sequence, the error probability of permutation index estimation conditioned by P_j is given by

$$P_{red} = (P_r |D_{j_1}| < \max P_r |D_m|) \text{ for } 1 \leq m \leq 2^n, m \neq j_1 \quad (8)$$

Where the D_{j_1} and D_m are decision variable at m^{th} and j_1^{th} correlator output. The error will occur only if any value of D_m can have a magnitude larger than D_{j_1} . To detect the first information bearing signal, the output of m^{th} correlator can have two values and can be rewritten as

$$D_m = \begin{cases} SS + SN + NN & m = j_1 \\ SI + SN + NN & m \neq j_1. \end{cases} \quad (9)$$

The correlation components can be calculated as

$$SS = X_\beta P_{j_1}^{-1} P_{j_1} X_\beta = X_\beta X_\beta^T = \sum_{k=1}^{\beta} x_k x_k \quad (10)$$

$$SN = X_\beta W_0 + W_\beta P_{j_1}^{-1} P_{j_1} X = \sum_{k=1}^{\beta} x_{k-\beta} w_k + \sum_{k=1}^{\beta} w_{k-\beta} x_k \quad (11)$$

$$NN = W_{\beta} P_{j_1}^{-1} W_0 = \sum_{k=1}^{\beta} w_{k-\beta} w'_k, \quad (12)$$

where w'_i is the permuted noise sample.

Based on the assumption that the correlation between noise sample w_i and chaotic samples x_j for all i and j is negligible, for sufficient value of β , then

$$E(D_{j_1}) = E(SS) + E(SN) + E(NN) = E\left(\sum_{k=1}^{\beta} x_k x_k\right) + 0 + 0 = \beta V(x) = \frac{L}{L+1} n E_b \quad (13)$$

$$V(SS) = V\left(\sum_{k=1}^{\beta} x_k x_k\right) = V\left(\sum_{k=1}^{\beta} x_k^2\right) = \frac{4}{5} \beta V(x) V(x) = \frac{4(L)^2}{5\beta(L+1)^2} n^2 E_b^2 \quad (14)$$

$$V(SN) = 2\beta V(x) V(w) = 2 \frac{Ln}{L+1} E_b N_0 \quad (15)$$

$$V(NN) = V(w) \cdot V(w') = \frac{\beta}{4} N_o^2. \quad (16)$$

While $E(D_m) \approx 0$, similarly

$$V(D_m) = V(SI) + V(SN) + V(NN) \quad (17)$$

$$= \frac{(L)^2 n^2}{\beta(L+1)^2} E_b^2 + 2 \frac{Ln}{(L+1)} E_b N_0 + \frac{\beta}{4} N_o^2 \quad (18)$$

The output of each $2^n - 1$ correlators D_m for $m \neq j_1$ are statistically independent random values characterized by a normal distribution with zero mean and can be given as

$$f_{D_m}(y) = \frac{1}{\sqrt{2\pi V(D_m)}} e^{-\frac{(y)^2}{2V(D_m)}} \quad (19)$$

While the correlator output conditioned by correct permutation can be given as

$$f_{D_{j_1}}(y) = \frac{1}{\sqrt{2\pi V(D_{j_1})}} e^{-\frac{(y - E(D_{j_1}))^2}{2V(D_{j_1})}} \quad (20)$$

It is easier to calculate the probability of correct permutation which is occurred only if magnitude of $D_{j_1} > D_1$, $D_{j_1} > D_2$ and ... $D_{j_1} > D_M$, therefore the probability of correct map detection can be given as [?]

$$p_{map} = 1 - \int_0^\infty F_{D_m}(y)^{2^n-1} f_{j_1}(D_{j_1})(y) dy, \quad (21)$$

where $F_{D_m}(y)$ is the commutative distribution function given by

$$F_{D_m}(y) = erf\left(\frac{y}{\sqrt{2\pi V(D_m)}}\right) \quad (22)$$

The overall BER of the system can be given by substitution on

$$BER_{SR-PI-DCSK} = \frac{2^{(n-1)}}{2^n - 1} \left[1 - \frac{1}{\sqrt{2\pi \frac{4(L)^2 n^2}{5\beta(L+1)^2} E_b^2 + 2 \frac{Ln}{L+1} E_b N_0 + \frac{\beta}{4} N_o^2}} \int_0^\infty erf\left(\frac{y}{\sqrt{2\pi \frac{(L)^2 n^2}{\beta(L+1)^2} E_b^2 + 2 \frac{Ln}{L+1} E_b N_0 + \frac{\beta}{4} N_o^2}}\right)^{2^n-1} e^{-\frac{(y-E(D_{j_1}))^2}{2V(D_{j_1})}} dy \right] \quad (23)$$

6 Experimental results

In this section, different standard chaos schemes including the recently proposed scheme have been simulated and compared with the suggested system in AWGN channel environment and with various E_b/N_0 . Furthermore, the proposed system has been compared with the standard PI-DCSK [?]. Analytic performance based on Eq. 23 has been compared with simulation results for different frame lengths. Finally, the effect of the spreading factors on the proposed scheme has been examined.

In Fig. 4, the SR-PI-DCSK is compared with the DCSK, CDSK, HE-DCSK, and TR-DCSK. The system outperforms the other systems by an average of 2 dB except for DCSK which exceeds the suggested system by 1 dB, although the proposed system offers a double bit rate. This is due to non-complete orthogonality at spreading factor $\beta = 100$. When the spreading factor is increased to $\beta = 150$, it can be easily noted that the SR-PI-DCSK system performance enhanced by an average of 3 dB for all other systems as shown in Fig. 5. Obviously, the superiority in the performance continue while spreading factor increased to $\beta = 200$ and $\beta = 300$ as shown in Fig. 6 and Fig. 7, respectively. This can be explained by the fact that, compared to other system chaos signal, the average transmitted signal energy per bit for the proposed system has been saved by $2L/(L+1) \approx 50\%$ compared to the standard systems to which corresponds to a gain or horizontal displacement of BER. In addition to the very low cross correlation value at the correlator output between the interference component.

Comparison of the SR-PI-DCSK system performance at various frame length has been demonstrated on Fig. 8, Fig. 9, Fig. 10 and Fig. 11. The comparison is performed at the increment trend of the spreading factor. It is obvious that the performance of the proposed system with frame length $L = 3$ is better than systems with the length of $L = 2$ and $L = 1$ or PI-DCSK [?]. It evident that the performance is degraded at a high value of β due to noise to noise (NN on Eq. 12) which at the correlator output.

A theoretical estimation of BER for the proposed system is developed using GA and validated using computer simulation. Excellent agreement between theoretical expression in Eq. 23 and simulation results that shown in Fig. 12, Fig. 13, Fig. 14 and Fig. 15 for $\beta = 100$, $\beta = 150$, $\beta = 300$ and $\beta = 500$, respectively. The results obtained clearly validate the expression derived.

Effect of increasing of spread factor β has been studied and illustrated in Fig. 16 at fixed value of E_b/N_0 (at 13 dB and 17 dB). It is clearly shown that the performance is enhanced as β increases and reach its ideal performance at $\beta = 100$, and this matched with the results shown in Fig. 4, Fig. 5, Fig. 6, and Fig. 7. After β reach 100, the performance starts to decrease with β due to dominance of noise to noise expression (NN) at high spreading factor as illustrated by the equation (23)

7 CONCLUSION

A new permutation based DCSK system named Single Reference-Permutation Index-Differential Chaos Shift Keying (SR-PI-DCSK) is proposed, designed, and validated through simulation. A theoretical formula to predict the bit error rate is developed and verified. The proposed system sends information symbols in a frame, each frame consists of a reference signal followed by a sequence of L information bearing signal. This reduces the energy requirement and enhanced the BER. The BER performance is simulated and compared with DCSK, CDSK, HE-DCSK, and PI-DCSK schemes. Results illustrate the system outperform other chaos based systems, particularly at large spreading factor. Comparison results illustrate the advantage of the proposed scheme specifically at moderate E_b/N_0 over the other schemes. Based on the GA method, theoretical prediction for BER is developed and compared with the simulation results. Excellent matching between the derived form and simulation results is noticed.
