14

15 **Abstract**

16 **Background:** Maldistribution of health workers between urban and rural areas has
17 been a critical difficulty in China. The shortage of health workers in disadvantaged
18 areas reduces access to essential health services delivery, and adversely affects the
19 population health. Policies on attracting health workers to locate in rural areas are
20 needed to be explored. In order to identify the appropriate incentives, we conducted a
21 discrete choice experiment to determine how specific job attributes might be valued
22 by final year students in medical university in Guizhou Province, China.

23 **Methods:** Attributes of potential job were developed through literature review,
24 in-depth semi-structured interviews and pretest. Salary, education opportunity,
25 transportation, job location, workload, essential equipment, medical order, and
26 identification ('bianzhi') were included. The questionnaire was formulated through a
27 fractional factorial experiment design using %MktRuns macros of SAS 9.4. All
28 medical and nursing students in the final year at Guizhou Medical University were
29 invited to participate in the study. Mixed logit model was used to estimate stated
30 preferences of attributes. Willingness to pay and uptake rates for a defined job were
31 also calculated based on the mixed logit estimates.

32 **Results:** The final sample comprised 787 respondents, including 388 medical students
33 and 399 nursing students. Attributes were statistically significant (with the exception
34 of once every two years for education opportunity) and had expected signs. The
35 results indicate that physical conflict between doctors and patients and identification
36 ('bianzhi') were two of the most important non-monetary job characteristics for both

37 medical and nursing students. And nursing students placed more value on
38 identification ('bianzhi'). Policy simulation suggests that as for the individual
39 incentive respondents were most sensitive to salary increasing. Incentive packages
40 effects were stronger for students from rural background.

41 **Conclusions:** Strategies on medical order, identification ('bianzhi') and salary should
42 be considered to attract final year medical and nursing students to work in rural areas.
43 In addition, specific recruitment policy design tailored for subgroups should be taken
44 into account.

45 **Keywords:** Discrete choice experiment, Job preferences, Health workers,
46 Recruitment

47 **Background**

48 The uneven distribution of health workers reduces access to essential health services
49 delivery, and contributes to inequalities in health outcomes [1]. As one study found
50 that, reductions in under-five mortality rate were associated with increased health
51 workers[2]. Several studies have cast light on the systematic categories of imbalances
52 in the health workforce, including geographic imbalances, institutional imbalances,
53 public/private imbalance, and profession/specialty imbalance[3]. Among all these
54 imbalance categories, the lack of health workers in disadvantaged areas will impede
55 the universal health coverage and ultimately adversely affect the population health
56 living in remote and rural areas[4]. As one study found that, reductions in under-five
57 mortality rate were associated with increased health workers[2]. Disparity between
58 urban and rural areas in terms of health workforce has become a critical health policy
59 concern in many countries [5, 6]. China is not an exception, since health workers are
60 inclined to serve in tertiary hospitals in urban areas rather than in primary care
61 facilities in rural areas because of working conditions, career development, etc.

62 China's higher education system reform has been launched in 1998, since then a
63 major expansion of universities has facilitated to a fast growth of health education[6].
64 However, a big dilemma is that faculty numbers might not have kept pace with
65 numeric expansion of students[7]. Although China's total health workforce rose
66 remarkably from 6.7 million people in 2006 to 10.2 million in 2014[8], a shortfall of
67 over 500 000 physicians exists in rural areas[9]. In addition, the low nurse to doctor
68 ratio (1.1:1) to some extent constrains the development of clinical practice [8]. Further,

69 the density of nurses in urban areas is much higher than in rural areas and the gap is
70 widening [10].

71 Undergraduate health students' job preferences will influence the distribution of
72 health workers in the future. Thus, it is necessary to elicit policy incentives specific
73 for final year medical and nursing students, which can be tailored to make the posts in
74 rural areas more attractive, since posts in primary care facilities in rural areas are
75 usually considered less desirable because of high workloads, inconvenient traffic and
76 poorly infrastructure[11]. Incentives to attract health workers to locate in
77 disadvantaged areas have been well described by World Health Organization(WHO)
78 including education interventions, regulatory interventions, financial incentives,
79 personal and professional support [12]. WHO also proposed that countries need to
80 identify the appropriate interventions that are suitable for their local context, given
81 diverse health labor market and local demand [13]. Thus, the development of such
82 strategies really needs a precise insight into job preferences of health workers in
83 various counties.

84 The policy implication could be elicited from the use of discrete choice experiment
85 (DCE) method. DCEs have been commonly used in health economics, while recently
86 determining health workers job preferences in human resource research field can be
87 informed by the results from this methodology. In particular, a user guide on how to
88 conduct a DCE for health workforce recruitment and retention in rural areas was
89 developed by WHO and other two agencies, which mentioned that DCE could assess
90 the stated preferences of health workers for a job [14]. The choice experiment is a

91 combination of the characteristics theory of demand and random utility theory [15].
92 The method assumes the utility associated with a good or service is made up of the
93 utilities of its attributes[16],which is well-established for identifying the relative value
94 that people place on factors (attributes) [17]. The benefit of DCE is that of
95 opportunity cost. Individuals want the best of everything, but when resources are
96 limited, the method gives a weighed relevance to distinguish which attributes are the
97 most highly valued. In addition, quantitative information on the relative strength of
98 the selected attributes could be provided, as well as the trade-offs between these
99 attributes and the probability of take-up of defined jobs [14, 18].

100 Under the circumstances of China's reform and opening-up, doctors has confronted
101 and undergone the challenges of ongoing economic reforms and medical reforms.
102 With the emergence of new problems such as violence against medical staff, previous
103 difficulties still exit, e.g. identification ('bianzhi'). The surge in hospital violence
104 seriously affects the normal medical order, which is a proper status where health
105 workers and patients in the medical relation share orderly interactions. And a
106 widespread concern among the health workers has been caused by the assaults on
107 them [19]. On the other hand, China had a special employment system from 1949 to
108 1978 in which the government decided the number of personnel for each employer,
109 which was called 'bianzhi'. But since the economic reforms in 1978, a transition in
110 employment system is the decrease of 'bianzhi' positions and the increase of
111 contract-based workers. However, 'bianzhi' positions are still highly valued by
112 Chinese public because of the benefits and belonging sense [20]. In our study, medical

113 order and 'bianzhi' were included as job factors to identify the impact on the
114 preference of medical students for job.

115 Undergraduates may have a lot of choices and puzzles when facing various jobs of
116 different characteristics. Where to locate, what kind of work can give them not only
117 bread and but also dignity, even safety may be weighed. Although there have been a
118 couple of studies to explore the job preferences of health workers using DCEs in
119 china[10, 21], and which found that identification ('bianzhi') , as well as income,
120 benefits, equipment, career development, respect from the community, training
121 opportunity, education environment for children could be the push and pull factors
122 affecting Chinese health workers' decision on location in rural areas [21, 22].
123 However, the paucity of evidence on how incentive policies influence undergraduate'
124 decision to work in rural areas is cause for concern. And to our knowledge, this is the
125 first study to explore the impact of medical order on rural recruitment. More evidence
126 would be needed to inform practical policy decisions. In this paper, we aim to explore
127 a set of factors that are amenable to job preferences among final year students, and to
128 assist policy-makers in designing better-informed interventions for attracting them to
129 rural areas.

130

131 **Methods**

132 **Study setting and sampling**

133 This research was conducted in Guizhou province, located in western-southern part of
134 China. This province was selected purposively for four reasons: 1) as one of the most

135 underdeveloped province in China, urbanization rate ranking was the last but one in
136 all provinces in 2015; and 2) the geographic access to health workers was poorly,
137 since Guizhou province is the only one which has no plains but hills among all the
138 provinces, villagers may climb a few mountains to see a doctor; 3) the proportion of
139 rural resident population was 56%, while the proportion of health workers working in
140 rural areas was 30%; 4) in 2016, the density of licensed (assistant) doctors in China
141 was 2.31 per 1,000 population, whereas in Guizhou province was 1.94. Density
142 figures for nurses were 2.54 and 2.42 per 1,000 population in China and Guizhou
143 province, respectively[23,30].

144 In this study we examined the preferences of Undergraduate health students who
145 are seen as the fresh blood of health professionals. China has a vast and complex
146 system of health professional education. The most common education program for
147 medical students is 5-year curricular plans, meanwhile 3-year schools after senior
148 high school or junior high school and 7-8-year degree programs exist all at once.
149 Graduates can be awarded Bachelor's degree after 5-year curricular plans, while
150 graduates for 3-year schools cannot get bachelor's degree and will be assistant doctors.
151 For 7-year degree program, graduates can be awarded Master's degree, and for 8-year
152 degree program, graduates can be awarded Doctoral degree. Graduates of 7-8-year
153 degree programs usually enter tertiary hospitals, medical colleges and research
154 institutions. For nursing students, 3-year and 4-year schools co-exist. Graduates can
155 be awarded Bachelor's degree after 4-year schools, while 3-year schools not.

156 Target group of our research was final year medical students of 5-year schools and

157 nursing students of 3-year and 4-year schools training to be doctors and nurses, since
158 doctors and nurses have been identified by health officers in Health Commission of
159 Guizhou Province as the most needed staffing to effectively run a primary health
160 facility through semi-structured interviews we have done in August in 2017. We
161 selected final year students because they had experienced the clinical training and
162 were considering career options but had not yet made their post decisions. Guizhou
163 Medical University was selected purposively for it was the most influential medical
164 school and had the most number of graduates in Guizhou province.

165 While exact recommendations vary, a minimum of between 20 and 50 respondents
166 per experiment group is required to reliably estimate respondent preferences[24].
167 Thus, all medical and nursing students in the final year at Guizhou Medical University
168 were invited to participate in the study (excluding the 33 students who participated in
169 the pilot test).

170

171 **Identification and selection of attributes and levels (instrument development)**

172 DCE is an evaluation method, which is founded on the random utility theory. This
173 theory of utility requires a multiple attribute approach that consists of breaking down
174 the examined good into its different components or attributes for which the levels
175 vary systematically between choice sets [25, 26]. The first stage of developing a DCE
176 tool involves identifying attributes and then determining the levels of these attributes.
177 DCE attributes were selected by literature review, semi-structured interviews and
178 pretests. Possible attributes (n=15) were identified through literature review, which

179 then were narrowed down through semi-structured interviews conducted with 23
180 doctors and 18 nurses present on the day of the visit. These interviewees were from
181 nine primary health facilities in Guizhou province. To ensure common views were
182 captured, we conducted the interviews in four counties and one district during July in
183 2017(TableA1). Semi-structured interviews with six senior government officers in
184 charge of the primary health care in Health Commission of Guizhou Province were
185 conducted to ensure the realistic concerning development of policy incentives.
186 Interviews were digitally recorded and transcribed. Thematic analysis and constant
187 comparison was used to analyze the data. Content analysis of current policy
188 documents was conducted. Prior to data collection, DCE instruments were pretested
189 once with final year medical students. Minor modification was made.

190 Informed by these work, eight attributes were important to warrant inclusion in the
191 final DCE (Box 1): salary, education opportunity, transportation, job location,
192 workload, essential equipment, medical order, and 'bianzhi'. Salary was meant the
193 monthly net salary (after tax). A salary attribute was always included in DCE studies,
194 for the estimation of willingness to pay (WTP) for improvements in other
195 attributes[21]. Given the hypothetical nature of the levels of attribute, and in order to
196 compare the job preferences between medical students and nursing students, the
197 difference of practical salary between the two groups was not shown in this study. The
198 lowest salary level included in the instrument represented the average salary estimated
199 through the interviews with health officers. Education opportunity represented the
200 training opportunity which should substantially improve health workers' clinical skills,

201 not like some ways, for example expert assistance for the primary health facilities
202 from upper hospitals which some interviewed health workers reflected they could not
203 improve as much as they expected through this way. As for the transportation attribute,
204 'inconvenient' was meant that from post location to living zone it would take almost
205 1.5 hours or more, 'convenient' was meant it would take around 0.5 hour or least. Job
206 location, the definition of location was according to the administrative division in
207 China. Villages and towns were corresponding to rural areas. Workload, given
208 working for 50 hours per week was common phenomena among health workers
209 known through interviews with health workers and officers mentioned above, 50
210 hours per week was the reference. Essential equipment was described as medical
211 equipment and facilities which was regular and equipped enough for common and
212 frequently-occurring disease. Medical order was included, because escalating
213 doctor-patient tension has been a serious concern in current China[19]. In addition,
214 our research team worked closely with the health officers in Health Commission of
215 Guizhou Province who requested that medical order related attributes should be
216 included in the DCE. Suit (synonymous with the terms 'lawsuit' or 'litigation' as
217 relevant throughout the document) was one of its levels we identified, which meant
218 that the medical dispute needs to be adjusted in court. Identification ('bianzhi'), 'iron
219 rice bowl' positions with life-time job security is called 'bianzhi' in China, as opposed
220 to 'bianzhi', contract-based health workers have fewer job benefits and less belonging
221 sense to the job[20]. In order to clarify the attributes and levels and confuse the
222 respondents least, most of them were described quantitatively and concretely. For

223 example, we used frequencies (e.g. once a year) to describe education opportunity
224 instead of qualitative description i.e. 'insufficient, some, sufficient'.

225

226 **Experimental design and choice set construction**

227 As described in Box 1, there were two attributes with four levels, another two
228 attributes with three levels and four attributes with two levels. This design generated
229 2304 ($4^2 \times 3^2 \times 2^4$) potential scenarios with different combinations of levels of the eight
230 job attributes and 2,653,056 $((2304 \times 2303)/2)$ potential choice tasks. As this was too
231 many to present to each individual, the number of potential scenarios was reduced by
232 a fractional factorial experiment design using %MktRuns macros of SAS 9.4 to
233 optimize D-efficiency, maximize level balance and orthogonality, and minimize
234 overlap among attributes levels, furthermore a restrictions macro was also used to
235 avoid dominated alternatives[27,33]. Dominance in a DCE means a participant always
236 selected job scenarios on the basis of one attribute.

237 The final design consisted of 40 sets. Systematic review identified that 16-20
238 choice tasks was the mode for previous DCEs administered to health workers[28]. In
239 order to not exhaust the respondents, the 40 sets were blocked into 2 questionnaire
240 versions, each containing 20 choice sets. The blocks were randomly allocated to the
241 respondents. Each choice set was comprised of two job scenarios (Job A and Job B)
242 (Figure A1). A forced choice approach was employed for two reasons: 1) to elicit
243 more information on respondents' preferences for the attributes; 2) since students had
244 not empirical understanding of the job in reality, the opt-out option (to choose their

245 current job) was not included. We used an unlabeled DCE, because some evidence
246 suggested that labels may distract respondents from job attributes and thus diminish
247 the reliability of estimates of job preferences[29]. The questionnaire was presented in
248 three sections. Section one was an introductory script. The purpose of this part was to
249 acclimate respondents to the hypothetical nature of the DCE they were about to take.
250 The telephone number of research group member was also in this part for the
251 interviewees to connect while they had problems during the process of filling in
252 questionnaires. Section two included socio-demographic characteristics, such as
253 gender, age and location of birth. Section three was 20 choice sets. The survey was
254 conducted during October and December 2017.

255

256 **Survey administration**

257 The self-administered questionnaire was emailed to the class tutor who uploaded it to
258 the Class QQ Population (instant message software, widely used in China), the
259 questionnaire was then downloaded by students who would send it to the class
260 monitor after finishing it. All final-year medical and nursing students in this school
261 were invited to participate except the students who participated in the pilot-testing.
262 The class monitor collected, packed and emailed the questionnaires to the research
263 group.

264

265 **Pilot-testing**

266 Prior to the start of data collection, we piloted with 33 medical students. This process

267 provided an opportunity to determine if the presentation was conceptually clear.
268 Minor correction was made. Respondents did not think 20 choice sets were a
269 cognitive burden, and they completed the survey within 20 minutes.

270

271 **Statistical analysis**

272 All data from the DCE questionnaires was entered and stored using Microsoft Excel
273 2010 (Microsoft Corporation, USA). Descriptive statistics were calculated for
274 demographic variables. The main effects mixed logit models were adopted to analyze
275 the DCE data.

276 Recently, the use of mixed logit models is increasing [1, 10, 15, 26, 30-38] which
277 take the preference heterogeneity among respondents into consideration. The
278 underpinning of discrete choice model is random utility theory, stipulating that
279 respondents as a rational economic individual consider all the relevant information
280 and choose the option that can maximize the utility. The utility of alternative i for
281 individual n in a choice situation j can be specified as:

$$282 U_{inj} = V_{inj} + \varepsilon_{inj}$$

$$283 i = A, B; \quad n = 1, \dots, n; \quad j = 1, \dots, 20$$

284 The utility is made up of two independent additive parts: a deterministic part, V_{inj} , and
285 a stochastic part, ε_{inj} . Where $V_{inj} = V(X_{inj}, \eta_n)$ is the systematic component of the utility
286 which is the explainable of the variance in the choice, with individual characteristics
287 η_n . The ε_{inj} is unobservable to the researcher and treated as independent and identical
288 distributed extreme value[21].

289 Assuming a linear additive utility function, the observable component for
 290 individual n for alternative i becomes $V_{inj} = \beta_n x_{inj}$, where $x_{inj} = (x_1, x_2, \dots, x_i)$ is a vector of
 291 attributes, each valued at a certain 'weight' $(\beta_1, \dots, \beta_i)$. Coefficient vector β_n varies in
 292 the population with density $(\beta_n | \theta)$, where θ are the true parameters. Thus, the
 293 probability of choosing alternative i from j alternatives is the standard logit formula:

$$L_{inj} = \frac{e^{\beta_n x_{inj}}}{\sum_j e^{\beta_n x_{jnj}}}$$

294 The modification in mixed logit is the researcher does not know the value of β_n or
 295 ε_{inj} . The solution of the equation requires integrating L_{inj} over all the possible values of
 296 β_n weighted by the density selected, usually the standard normal distribution. The
 297 probability of the observed sequence of choices for a given choice set becomes[31]:

$$P_{inj}(\theta) = \int L_{inj} f(\beta_n | \theta) d\beta_n$$

298 The estimated coefficients can only give information about the direction and
 299 significance of the effect of changing the levels of one attribute, all other things being
 300 equal. However, analysis on the valuation and comparison of different policies may be
 301 the most instructive part for policy makers. We then use the value of coefficients to
 302 calculate willingness to pay (WTP) and policy simulations.

303 Willingness to pay estimates were calculated by dividing attribute coefficients by
 304 the salary coefficient for each model, conveying in monetary terms respondents'
 305 preferences for one level of an attribute as compared to the reference level. The WTP
 306 for attribute x is given by the following equation:

$$WTP(x) = - \frac{\beta_n}{\alpha_1 + 2\alpha_2 w_{inj}}$$

307 Where α_1 , α_2 are the coefficients for the income and income squared, w_{inj} is the
308 attribute of income[39].

309 A simulation study was conducted to assess the potential impact of various
310 incentives that can be used to attract undergraduates to rural areas. Predicted
311 probabilities calculated to estimate an uptake rate of choosing a 'rural job' rather than
312 an 'urban job' can be depicted as [26]:

$$P_{\text{rural}} = \frac{\text{Exp}(V_{\text{rural}})}{\text{Exp}(V_{\text{rural}}) + \text{Exp}(V_{\text{urban}})}$$

313 All attributes variables were coded as dummy variables except for salary, which
314 was specified as continuous variable to facilitate the calculation of willingness to pay.
315 Sex and rural-urban background information was then used to divide the sample into
316 subgroups and separate analysis on each subgroup was carried out. All mixed logit
317 models were fit using StataMP 14's mixlogit command (Stata Corporation, USA), and
318 were specified with 500 Halton draws.

319 Several validity tests were conducted to determine the appropriateness of model
320 specifications. The theoretical validity of the model was assessed by determining
321 whether the coefficients were of the anticipated sign. We repeated the analysis using
322 conditional logit models (all data available from the authors). In this study, the results
323 from each conditional logit model were not substantively different from the mixed
324 logit model. As for the external validity test, telephone number of students was
325 acquired on a voluntary basis at the end of the questionnaire in order to follow them in
326 the future and ascertain the actual choices they made after graduation.

327

328 **Results**

329 Of 1168 eligible final year medical and nursing students in Guizhou medical
330 university, overall 879 (75%) agreed to participate in the survey: 438 were medical
331 students and 441 were nursing students. The response rates were 61% and 97%,
332 respectively. Questionnaires that were not completed were excluded from the sample,
333 thus the final sample comprised 787 respondents, including 388 medical students and
334 399 nursing students. The questionnaire qualification rates were 89% and 90%,
335 respectively.

336 The mean age of medical and nursing students were all 24 years old (SD=1.3), with
337 ages ranging from 21 to 29 years. Nursing students were predominantly female (92%),
338 while 58% of medical students were female. Medical students of rural origin were
339 52%, whereas 66% of nursing students had a rural background (Table 1).

340

341 **Preferences for job attributes**

342 Output from two mixed logit models for medical students and nursing students fit to
343 DCE data are represented in Table 2. The signs on all estimates were as expected,
344 which implies that respondents derived a higher level of utility from the superior
345 attribute level and made rational choices[16]. As for our study, workload of 60 hours
346 per week and tuneless medical order had an adverse effect on preferences while all the
347 others had the positive effects. Attributes were statistically significant at the 5% level
348 (with the exception of once every two years for education opportunity), indicating that
349 they impact on the probability of choosing a job. Physical conflict, 'bianzhi' and

350 essential equipment were major predictors of the preference for medical students
351 ($\beta=-0.893$, $\beta=0.411$, $\beta=0.271$, respectively), while physical conflict, 'bianzhi', and
352 transportation were major predictors of the preference for nursing students ($\beta=-0.498$,
353 $\beta=0.454$, $\beta=0.359$, respectively). From the standard deviation of the regression
354 coefficients, we find significant preferences heterogeneity exists over transportation,
355 workload of 40 hours per week, essential equipment, physical conflict, suit and
356 'bianzhi' for both medical and nursing students. Job location appeared to be an
357 important attribute for both medical and nursing students, and there was no preference
358 heterogeneity for nursing students' preferences while had for medical students.

359

360 **Willingness to pay**

361 Table 3 shows the results of the WTP calculation. Mean utility coefficients are the
362 basis for estimations of WTP, which can be compared across different groups[30].
363 These measures explain how much of the salary a final year student is willing to
364 sacrifice to have an improvement on a particular job attribute. The WTP for medical
365 order gave us a clear indication about the importance of harmonious medical order,
366 the medical students and nursing students had to be compensated with RMB 3138
367 (US\$ 464) and RMB 1719 (US\$ 254) per month to take a job with physical conflict,
368 respectively. The medical students and nursing students were willing to pay RMB
369 1443 (US\$ 213) and RMB 1566 (US\$ 231) in order to obtain 'bianzhi', respectively.
370 In terms of essential equipment, medical students and nursing students were willing to
371 reduce the almost same monthly salary that was RMB 954 (US\$ 141) to have a job

372 with adequate essential equipment.

373 Analysis for subgroups on sex for medical students suggests that women would be
374 compensated with more money for tuneless medical order than men. And men would
375 pay more money to obtain the other attributes than women with the exception of
376 adequate essential equipment. Medical students from rural background would pay or
377 be compensated with more money for all attributes than those from urban background
378 except the job location of city (Table A2).

379

380 **Policy simulation**

381 The relative impact of DCE attributes is often better appreciated to predict the impact
382 of different policies. Figure 1 showed the likely uptake of rural jobs to reflect the
383 relative effectiveness of different policies proposing improved rural jobs, for the
384 medical and nursing students, as well as the rural and urban background students. Not
385 surprisingly, urban jobs were more strongly preferred than rural ones, especially for
386 nursing students and urban background students (the total uptake rate for rural
387 postings at the baseline was 2% and 4%, respectively). It appears that of all the single
388 incentives that could be introduced to improve the current rural job offers, the most
389 effective would be to offer rural posts with increased salary for the four groups. As
390 salary level went up, the impact on rural recruitment would increase. As the
391 simulation result showed, if the salary increase from 5000RMB to 7000RMB, the
392 probability of accepting the job would increase by 19%. Intervention packages were
393 also explored (Table 4). For example, intervention packages including salary of RMB

394 5000 (US\$ 739) per month, educational opportunities for once a year and having
395 'bianzhi' would yield the same impact as the scenario of salary of 7000RMB
396 (US\$ 1035) per month for medical students. Incentive packages effects were stronger
397 for students from rural background than those from urban background. Nursing
398 students were more responsive to intervention policies, although they were less likely
399 to choose rural jobs at the baseline.

400 **Discussion**

401 In the absence of any well-designed studies using revealed preference data, we
402 conducted a DCE among final-year health students in order to identify a better
403 understanding of their preferences for job attributes. Effective interventions need to be
404 matched with their job preferences and expectations. In addition, it is vitally important
405 to ensure that health workforce incentive policies are developed and evaluated on the
406 basis of comprehensive empirical evidence which could stem from this rigorous
407 methodology in our study. Further, DCEs are useful in that they can examine the
408 likely effects of policies that have not been executed, thereby providing important
409 information to guide the design of such incentives.

410 This DCE analysis offers important insights into the nature of the health workers
411 labor market in China. We found that final year health students preferred a job with
412 sufficient opportunities for education, adequate equipment and city location, light
413 working strength, convenient transportation, harmonious medical order, 'bianzhi',
414 higher monthly salary. This finding suggested that there could be a range of policy
415 interventions to improve the probability of choosing a rural job.

416 Our findings are in agreement with results of other studies. Education opportunity,
417 equipment, workload and transportation were also valued by other studies [15, 36, 40].
418 The lack of a significant effect for once every two years of educational opportunity
419 indicated that it has a limited effect on determining job selection. The fact that
420 respondents gave the high value to training opportunity for once a year implied that
421 policy options should focus on the factor. This finding echoes the DCE conducted for
422 students in Tanzania, revealing that they are eager to gain more knowledge[39]. For
423 educational opportunities, the government might consider a program where health
424 workers in rural areas are guaranteed access to educational training courses that are
425 most in demand and at least for once a year.

426 We found that adequate health facility equipment is an important determinant of job
427 choice. This is particularly true for medical and nursing students, who are often
428 disappointed by the gap between what they have been taught to do, often based in a
429 tertiary hospital infrastructure, and the availability of equipment in rural health
430 facilities where they are expected to work after the graduation. These results are
431 consistent with those from other DCEs [13, 35, 37, 38, 41]. Also, a review paper on
432 health worker's motivation and retention indicates that the improvement of hospital
433 infrastructure and resource available could increase retention[42].

434 Subsequently, we found that respondents wished to have adequate leisure time and
435 there were some aversion to higher workload. A generational shift in the health
436 students could be likely the reason. The respondents were the so-called generation
437 post-90s, who have grown up after China's reform and opening up, and with the

438 weakening sense of material deprivation which has been strongly had by the
439 generation post-70s and 80s. The belief of hard working for food may be away, and
440 the life style to control over their own spare time may be popular with them. As a
441 result, unlike their parents, working for more hours may not be appreciated by the
442 new power of the workforce market. Therefore, it will be necessary for authority to
443 reconcile work with rest in the future in order to make working in rural areas
444 sufficiently attractive to future health workers.

445 The result of our study highlighted the importance of convenient traffic. The
446 responsibility for creating such an environment will require an integrated approach
447 that necessarily goes beyond the health commission and include other departments
448 (e.g. finance, road).

449 Both medical students and nursing students placed high adverse value on tuneless
450 medical order, which was consistent with the context of tense relationship between
451 doctor and patient in China. Indeed, there are complaints among patients over the lack
452 of communication and empathy from doctors, and then the emerging phenomena are
453 widespread physical attacks on doctors[43]. Patients are given a strong impression
454 that health workers pay more attention to earnings than the patients themselves.
455 Gradually, health workers in medical facilities lose the trust and respect from patients.
456 However, one study in China showed that, from the perspective of health workers,
457 respect from community would be of great importance for them[21]. The DCE
458 information presented here may be used to inform the development of specific policy
459 intervention. Given the high doctor-patient tensions in China and the results of our

460 studies, the introduction of humanistic practice and the inculcation of professional
461 norms in medical schools could be urgent and essential[8]. 'Physical conflict' was the
462 most disliked scenario for medical and nursing students, followed by 'suit'. The
463 findings suggest that these students place more value on their life safety, rather than
464 medical event that could be solved through suit in court. Thus, in order to attract final
465 year students to locate in positions in disadvantaged areas, regulations and institutions
466 need to be improved to protect the safety of them.

467 Not surprisingly, 'bianzhi' had a large effect on job preferences. This key finding
468 has important policy implications. The majority of health workers in China work at
469 state-owned health facilities, 'bianzhi' can attach them with not only identification
470 from the government, but also corresponding benefits. Nursing students were willing
471 to pay more money to obtain 'bianzhi' than medical students, partly because of a high
472 utilization of contract-based nurses as opposed to 'bianzhi' nurses in China and the
473 inequities between the two types of nurses in terms of wages and job-related benefits.
474 Further, study finds that the disparities may adversely affect both nurse and patient
475 satisfaction in hospitals [20]. In real life, such environments are hard to change, but its
476 substantial impact on job preferences should be considered in health policy
477 discussions. For example, 'equal pay for equal work' strategy could be emphasized by
478 government in order to eliminate the disparities between 'bianzhi' and contract-based.

479 Our findings confirm that financial incentives are very important in attracting final
480 year students to locate in a rural posting. Final year health students viewed a higher
481 salary as a very important attribute. This reinforces previous studies in China [33],

482 which might be due to the fact that they are less satisfied with their salaries. As
483 Chinese health students still value the most fundamental needs, the lowest level of
484 needs in Maslow's theory, that is basic needs for safety[21]. From a health policy
485 makers' perspective, future programs should focus on not only non-financial strategies,
486 like educational opportunities or adequate equipment, but also financial incentives.
487 Unlike several studies showing that financial incentives were not found to be most
488 powerful policy levers [13, 26, 28, 31, 33, 36, 38, 44]. However, our findings
489 conformed that monthly income had a significant impact on the job choices of
490 undergraduate health students, similar with other studies [10, 37, 45].

491 Willingness to pay was used as an estimate of the minimum compensation. The
492 WTP results from the sub-group analysis on sex for medical students showed that
493 women would pay more money for harmonious medical order than men. As a result,
494 female doctors could be considered to be absorbed in the clinical team to smooth the
495 relationship between doctor and patient. Policymakers could target interventions to
496 different sub-groups of students or at least consider the differential impact in their
497 planning.

498 Our studies found that medical students from rural background would pay more
499 money on the all attributes of the hypothesized work with the exception of rural job
500 location. This finding is in line with previous research [26], but is somewhat at odds
501 with study in India [46]. It follows that the rural shortage of health workers could be
502 mitigated to some extent by preferential admission of health students from rural areas.
503 On the other hand, we could infer that if students with rural background can obtain the

504 potential work, they maybe cherish the job opportunity. So these were all prompts that
505 need to be taken into account when planning an attraction strategy. This also suggests
506 that preferential selection of rural students by training institutions can be an effective
507 strategy, and it also lends support to claim that student selection policies are a key
508 important of human resource intervention packages. This could be considered, e.g.,
509 through a scholarship or student loan scheme for students who are from a rural area
510 and who are willing to accept a job in a rural area upon completing their study.

511 The results of policy simulation indicate if these forms of incentives are provided,
512 medical and nursing students would take up the job even if it is in a rural area. From a
513 policy perspective, salary increasing would have the largest effect on recruitment,
514 concurring with previous studies especially conducted in poorer areas [1, 36]. Besides,
515 policy makers should attach greater importance to the recruitment of nurses in rural
516 areas. However, nursing students would be more sensitive to policy interventions
517 although they were unwillingly to locate in rural areas at the base line. Some have
518 argued that packages of interventions are essential for improving the distribution
519 human resources, and DCEs are one of the few methods available for comparing such
520 packages. Mounting evidence indicates that incentive packages may be more effective
521 [18]. This study has examined the likely effect of incentive packages on the
522 probability of attracting students to rural areas, and also confirms the importance of
523 developing incentive packages.

524 This study had several limitations. First, the stated preference method used, even if
525 it allowed us to determine relative strengths of the different attributes, cannot fully

526 anticipate the decisions eventually made by participants in real life situations. In order
527 to follow them along time to ascertain the actual choices they made, the respondents
528 were asked to provide telephone number on the basis of voluntary. Second, the
529 diverse intrinsic and extrinsic factors influencing job choices in real life are amenable
530 to change over time, and this need to be considered when designing recruitment
531 policies. Third, this research was conducted in Guizhou province, so if the findings
532 can be generalized to other place should be considered deliberately. Fourth, our
533 research did not consider the costs of each type of incentives, which is also an
534 important aspect of any incentive strategies. Further research should be on costs
535 information and monetary valuation of different policies to identify the most cost
536 effective one affecting health students' job choices.

537

538 **Conclusions**

539 The results of this study help develop priorities for the human resources for health
540 reforms currently on the policy agenda in China and add evidence to the literature on
541 job preferences of final year medical and nursing students, examining the relative
542 importance of factors influencing their job choices. Our research suggests that a
543 variety of possibilities exist to improve doctors and nurses' deployment in rural setting
544 e.g. increasing salary, providing harmonious medical order and eliminating the
545 disparities between 'bianzhi' and contract-based. These findings pose major challenges
546 for planning human resources policies aimed at prioritizing rural areas. Meanwhile,
547 subgroup analysis indicates that one uniform recruitment policy is not recommended.

548 The results presented here should be considered by policy makers for its
549 implementation, while weighing carefully the labor market and policy cost.

*** $P < 0.01$, ** $P < 0.05$.
SD, standard deviation.
SE, standard error.

710 ^aThe coefficient represents the mean relative utility of each attribute conditional on
711 other attributes in a choice set, while the standard deviation of the random
712 coefficients reflects the degree of heterogeneity in respondent preferences for a given
713 attribute.
714 ^bContinuous variable; the coefficient represents the magnitude of increase in utility by
715 having one extra RMB.
716 ^cCompared with once every five years.
717 ^dCompared with inconvenient transportation.
718 ^eCompared with rural job location.
719 ^fCompared with 50 hours per week.
720 ^gCompared with inadequate essential equipment.
721 ^hCompared with no quarrel, physical conflict and suit.
722 ⁱCompared with no 'bianzhi'.
