7  
8   **Abstract**

9   An experimental investigation of low temperature SO<sub>2</sub> removal by porous sodium carbonate was  
10 carried out by thermogravimetry. As well as, applied mathematical modeling based on the random  
11 pore model was employed to kinetic study of this reaction. The experiments were performed at  
12 various temperatures (100-250 °C) and different SO<sub>2</sub> concentrations (0.13-1.12 vol%). The initial  
13 slopes procedure was used to determine dependency of the reaction rate constants versus  
14 temperature. First-order kinetic with respect to gaseous reactant was found and value of activation  
15 energy was attained as 22.5 kJ mol<sup>-1</sup>. Product layer diffusion coefficients were evaluated by the  
16 best fitting of experimental data with the model predictions. These random pore model predictions  
17 indicated good agreement with experimental conversion-time data at various conditions. The  
18 resulted kinetic parameters were available for engineering calculations of SO<sub>2</sub> abatement from  
19 the coal-based power plants by low-temperature flue gas desulfurization.

27 **1. Introduction**

28 **1.1 Background Information**

29 One of the significant air contaminant which causes acid rain is sulfur dioxide. Sulfuric acid  
30 formed by the reaction of SO<sub>2</sub> with water vapor in the air generates acid rain afterward. Creation  
31 of acidic lakes, reduction of soil fertility, damaging forests, and corrosive results on stones and  
32 metals are some of the acid rain's destructive impacts. Therefore, lots of industries require to  
33 develop appropriate SO<sub>2</sub> removal procedures because of the environmental hazards of this air  
34 pollutant.

35 Power plants based on coal, roasting units of extractive metallurgical plants (copper and zinc) and  
36 refineries of natural gas are the sulfur dioxide's major sources (Petheram 2002). Several SO<sub>2</sub>  
37 emission controller rules are established for the mobile sources. European Union limited the sulfur  
38 values in gasoline and gas-oil to 10 ppm since 2010 (Stanislaus et al. 2010). Consequently,  
39 modified catalysts have been presented for petroleum fuels hydrotreating (Chen et al. 2010, Yin et  
40 al. 2011). As well as to increase SO<sub>2</sub> removal yield from the stationary sources, recent studies  
41 focused on different Flue Gas Desulfurization (FGD) methods.

42 FGD technologies include throw-away and regenerative processes (Kirk et al. 1949). Throw-away  
43 procedures are suitable for based coal power plants within 1000 ppm SO<sub>2</sub> concentrations. The  
44 general sorbent in these processes is lime (CaO). However, lime reaction with sulfur dioxide is  
45 accomplished at high temperatures (about 800 °C). Moreover, incomplete conversion can be  
46 occurred owing to pore mouth obstruction (Z=3) (Ale Ebrahim 2010).

47 In addition, wet and dry regenerative processes are appropriate with high SO<sub>2</sub> concentrations in  
48 several metallurgical systems. SO<sub>2</sub> absorbs by Na<sub>2</sub>SO<sub>3</sub> solution and strips in wet regenerative FGD  
49 method. In dry regenerative FGD method, CuSO<sub>4</sub> produced by the reaction of SO<sub>2</sub> with CuO.  
50 Then, CuO regenerated with reducing CuSO<sub>4</sub> by H<sub>2</sub>. The concentrated SO<sub>2</sub> stream in both  
51 regenerative processes should be reduced by methane (Mousavi et al. 2018, Sohn & Kim 2002).

52 Metal oxides and metal carbonates are the current adsorbents of throw-away processes consist of  
53 CaO (lime), MgO, Na<sub>2</sub>CO<sub>3</sub>, K<sub>2</sub>CO<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, etc. The main characteristic of these processes are  
54 simplicity of operation and economic efficiency (Gray & Jarvis 2020, Jia et al. 2007, Tseng & Wey

55 2004). Major advantage of sodium carbonate is its ability to remove SO<sub>2</sub> at low temperatures  
56 (about 200 °C). The Na<sub>2</sub>CO<sub>3</sub> sorbent base FGD reaction can be written as:

## 58 **1.2 Literature Review**

59 To investigate performance of sulfur dioxide removal by sodium carbonate several experimental  
60 studies have been done in the literature.

61 Dry sodium injection has been studied by the Electric Power Research Institute (EPRI) since 1977.  
62 This material tested as a solid sorbent (Bland 1990). The related test results demonstrate that SO<sub>2</sub>  
63 reduce 70-90% for subbituminous coals combustion with a different sorbents based on sodium,  
64 which all of them contain a considerable ratio of sodium bicarbonate.

65 Several studies were conducted to investigate the influence of NaHCO<sub>3</sub> thermal decomposition to  
66 Na<sub>2</sub>CO<sub>3</sub> on SO<sub>2</sub> absorption efficiency (Carson 1980, Dal Pozzo et al. 2019, Erdos et al. 1989,  
67 Knight 1977, Mocek &Beruto 1986). These reports indicated that gas temperatures between 120-  
68 175 °C showed the best performance for SO<sub>2</sub> scrubbing when the initial substance is sodium  
69 bicarbonate.

70 Han et al. described for the first time that Na<sub>2</sub>CO<sub>3</sub> additive can promote the sulfate conversion of  
71 limestone due to the enhanced surface area and tuned pore size distribution (Han et al. 2017). A  
72 packed scrubber with absorbents (limestone and sodium bicarbonate) was used by Ghorbani et al.  
73 to measure the concentration of sulfur dioxide at the inlet and outlet of scrubber. The results  
74 presented the more SO<sub>2</sub> removal efficiency by using these absorbents with cation surfactants  
75 (ghorbani shahna et al. 2017).

76 A non-isothermal thermogravimetric analysis was used by Wu et al. to determine the intrinsic  
77 kinetics of the NaHCO<sub>3</sub> to Na<sub>2</sub>CO<sub>3</sub> decomposition reaction. They reported activation energy as  
78 25.3 kcal mol<sup>-1</sup> for sodium bicarbonate decomposition. They found that elevating the temperature  
79 of decomposition from 120 to 230 °C enhances pore diameter from 180 to 210 nm (Wu &Shih  
80 1993).

81 Mortson et al. applied regenerated sodium bicarbonate/carbonate to remove SO<sub>2</sub> and NO<sub>x</sub> using  
82 an advance and economic FGD technology developed by AIRborne Technologies Inc. (ATI). High  
83 SO<sub>2</sub> removal yield and production of different fertilizers reported in this work (Mortson &Telesz  
84 2001).

85 Guangwen et al. used a powder-particle fluidized bed reactor to absorb SO<sub>2</sub> and NO by  
86 Na<sub>2</sub>CO<sub>3</sub>/Al<sub>2</sub>O<sub>3</sub>. As well as they examined different effective parameters, such as reaction  
87 temperature, fraction of mixtures in flue gas, and sorbent size (Xu et al. 2000).

88 Walawska et al. studied on structural factors of particle. In addition, mechanically and thermally  
89 activated sodium bicarbonate were considered. Sodium carbonate showed better removal yield  
90 than sodium bicarbonate (Walawska et al. 2014).

91 Ma et al. presented a concept test of NOXSO flue gas treatment process at three scales of 0.017,  
92 0.06 and 0.75 MW power plants (Ma &Haslbeck 1993).

93 To explain the NaHCO<sub>3</sub> and SO<sub>2</sub> reaction, Keener et al. employed shrinking core model (with  
94 neglecting solid reactant porosity). In order to deduce the rate constant expression, kinetic data  
95 were exported from this model. The measured activation energy (56.4 kJmol<sup>-1</sup>) indicates  
96 dependency of rate constant to temperature (Keener &Khang 1993).

97 Kimura et al. studied the SO<sub>2</sub>-Na<sub>2</sub>CO<sub>3</sub> reaction kinetics in the range of 80-140 °C, constant SO<sub>2</sub>  
98 concentration of 0.3% with thermogravimetric analysis data. Because of rapid reaction, particular  
99 precautions were affected to operate such that transport resistance did not change the results. Rate  
100 constants were estimated from the suggested mechanism and the experimental data (Kimura  
101 &Smith 1987). However, SO<sub>2</sub> diffusion resistance between Na<sub>2</sub>CO<sub>3</sub> nano-grains was neglected  
102 (Kimura &Smith 1987).

103 Ebrahimi et al. developed a model based on film theory for the SO<sub>2</sub> removal by NaHCO<sub>3</sub>/Na<sub>2</sub>CO<sub>3</sub>  
104 solution in a packed tower. This model includes diffusion and reaction processes, also  
105 thermodynamic equilibrium was considered for reactants in the bulk fluid (Ebrahimi et al. 2003).

106 Prada et al. designed a fixed-bed reactor to remove SO<sub>2</sub> in flue gases with sodium bicarbonate.  
107 Experiments were performed for 1500 ppm SO<sub>2</sub> and temperatures above 122 °C. In addition, a  
108 solution technique was used to predict the performance of reaction in this system with respect to

109 the length of reactor. This work showed better economic efficiency than SO<sub>2</sub> elimination with  
110 activated carbon for small-scale FGD applications (Charry Prada et al. 2019).

### 111 **1.3 Goals and Importance of the Present Study**

112 As mentioned, lime-based FGD systems are only performed at high temperatures (about 800 °C).  
113 In addition, incomplete conversion phenomenon of CaO reaction with SO<sub>2</sub> occurs due to pore  
114 mouth blockage (gypsum molar volume is very higher than lime, or  $Z=3$ ). Therefore, lime  
115 consumption is high and lime/gypsum mixture cannot be used as a byproduct. On the other hand,  
116 Na<sub>2</sub>CO<sub>3</sub> can remove SO<sub>2</sub> at low temperatures (about 200 °C). Other advantage of Na<sub>2</sub>CO<sub>3</sub> FGD  
117 system is its lower Z value ( $Z=1.28$ ), which means high possibility of complete conversion in  
118 Na<sub>2</sub>CO<sub>3</sub> reaction with SO<sub>2</sub>. Consequently, SO<sub>2</sub> removal by Na<sub>2</sub>CO<sub>3</sub> can be accomplished in low  
119 temperature flue gas ducts and sorbent consumption is low due to complete conversions.

120 To kinetic studies of non-catalytic gas-solid reactions, several mathematical models such as  
121 Modified grain model and RPM have been applied yet. These models can predict alteration of  
122 solid structural and specifically partial conversion. Really, industrial sorbents react on the interior  
123 areas of pores with a pore size distribution (PSD). Modified grain model simplification assumption  
124 is considering of porous solid contains of uniform fine grains which reaction occurs on their  
125 surfaces. It was confirmed that RPM accuracy for predicting conversion-time profiles is higher  
126 than modified grain model, due to considering of real PSD of the porous sorbent (Bahrami et al.  
127 2015).

128 As expressed in section 1.2, literature kinetic studies on the reaction of Na<sub>2</sub>CO<sub>3</sub> with SO<sub>2</sub> are very  
129 scarce. For example, Keener et al. (Keener &Khang 1993) applied sharp interface model for this  
130 reaction, while the resulted kinetic parameters seem insecure due to neglecting internal surfaces of  
131 sodium carbonate sorbent. On the other hand, Kimura et al. (Kimura &Smith 1987) considered a  
132 porous model, while neglecting diffusion resistance between Na<sub>2</sub>CO<sub>3</sub> nano-grains is questionable.  
133 Ultimately, comprehensive kinetic study of SO<sub>2</sub> reaction with Na<sub>2</sub>CO<sub>3</sub> which is not accomplished  
134 until now, is highly necessary for determining accurate inherent kinetic parameters. Therefore, the  
135 scope of the present work is complete kinetic study of SO<sub>2</sub> reaction with Na<sub>2</sub>CO<sub>3</sub> using  
136 sophisticated RPM considering concentration dependency and using real PSD of the porous solid.  
137 The resulted kinetic parameters are required for design of low temperature FGD reactors.

138 In this study, to determine the conversion-time profile data of  $\text{Na}_2\text{CO}_3$  reaction with  $\text{SO}_2$ ,  
139 isothermal thermogravimetry was used at predefined concentrations and temperatures. Moreover,  
140 precise modelling of  $\text{Na}_2\text{CO}_3$  reaction with  $\text{SO}_2$  is carried out by RPM. To evaluate the PSD,  
141 mercury porosimetry and nitrogen adsorption were applied. As well as, the appropriate order of  
142 the reaction is estimated. Initial slopes of conversion-time curves at several temperatures are used  
143 to determine intrinsic rate constants. The whole conversion-time profiles are employed to estimate  
144 the product layer diffusion coefficients. The comparison between measured RPM data and  
145 experimental data at various operating conditions displayed good agreement eventually.

146

## 147 **2. Materials and Methods**

### 148 **2.1 Raw Materials**

149 To kinetic study of this reaction, pure sodium bicarbonate powder (Chem-Lab) was used as the  
150 starting material. 85 mg pellets were constructed in a 10 mm diameter cylindrical mould by 6 bar  
151 hydraulic press with 1 mm thickness. The slab pellet was placed in a thermogravimeter and was  
152 heated up to temperature range of 100-250 °C for 30 minutes. Thus, a porous sodium carbonate  
153 pellet ready for reaction with different sulfur dioxide concentrations was prepared by thermal  
154 decomposition. The high porosity of the pellet is due to the release of water and carbon dioxide  
155 during this calcination step. The gaseous mixture of zero air and  $\text{SO}_2$  (99.95 %) was used as a  
156 reactant in this study.

### 157 **2.2 Equipment**

158 A Rheometric Scientific thermogravimeter (TG) was employed in this work that can operate at an  
159 isothermal condition with 1°C deviation. An experimental setup's schematic diagram is provided  
160 in Fig. 1. The slab pellets contact better with gaseous stream in TG by placing in a platinum basket.  
161 Zero air stream ( $150 \text{ cm}^3 \text{ min}^{-1}$ ) was utilized to purge the TG furnace and the sample was heated  
162 by a rate of  $30 \text{ }^\circ\text{C} \cdot \text{min}^{-1}$  to attain the reaction temperature. Then, the calcination was carried out in  
163 reaction temperature for 30 minutes. As a result, an extremely porous sodium carbonate pellet was  
164 provided. Then, in an isothermal step, a mixture of  $\text{SO}_2$  and zero air was injected into TG at a pre-

165 defined concentration. Thus,  $\text{Na}_2\text{CO}_3$  reacted by  $\text{SO}_2$  and TG device measured the weight changes  
166 of the pellet at various constant temperatures.

### 167 **2.3 Sample Characterization**

168 Nitrogen adsorption by Autosorb-1MP from Quantachrome for determination the micro and  
169 mesopores of the pellet (by a 55-point test) and mercury porosimetry for evaluation of macropores  
170 were utilized to obtain the  $\text{Na}_2\text{CO}_3$  pellet's whole PSD. Two methods, Horvath-Kawazoe (HK)  
171 and Barrett-Joyner-Halenda (BJH), were used for calculating the volume  
172 of micropores and mesopores from the nitrogen adsorption test. Furthermore, Washburn equation  
173 was used for evaluation of macropores from mercury porosimetry test. Consequently, the  
174 whole PSD of the porous  $\text{Na}_2\text{CO}_3$  pellet in the range of 0.3-1000 nm was obtained which is  
175 presented in Fig. 2.

176 Fig.3 displays the SEM pictures of the raw slab, after calcination at 150 °C, after reaction with  $\text{SO}_2$   
177 at 150 °C (52% conversion), and 225 °C (75% conversion). It is obvious from this figure that due  
178 to the release of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  molecules from the sample, porosity increased after calcination.  
179 Then, owing to formation of the product layer around the pores, porosity decreased during the  
180 reaction of the pellet with  $\text{SO}_2$ . In addition, the reduction in the pellet porosity at 225 °C is more  
181 significant than 150 °C, due to the higher reaction rate and higher product layer thickness.

182 Finally, the XRD pattern of reacted pellet showed both  $\text{Na}_2\text{CO}_3$  and  $\text{Na}_2\text{SO}_4$  phases, which  
183 emphasized the ability to react and removal of  $\text{SO}_2$  by  $\text{Na}_2\text{CO}_3$ .

184

### 185 **3. Kinetic Modeling**

186 The most sophisticated RPM model which was originally demonstrated by Bhatia and Perlmutter  
187 (Bhatia &Perlmutter 1981) is employed for precise kinetic study by considering different pore  
188 diameters and structural alteration (Moshiri et al. 2014, Ramachandran &Doraiswamy 1982). The  
189 assumptions of this model are the pseudo-steady state for gas concentration, the irreversible  
190 reaction, negligible effect of the bulk flow, the isothermal system and constant size of the pellet  
191 (Ale Ebrahim 2010, Bahrami et al. 2014). The dimensionless differential equations for a slab pellet

192 and an arbitrary concentration dependency are as follows (Bahrami et al. 2014, Bahrami et al.  
193 2016):

$$194 \quad \frac{\partial}{\partial y} \left( \delta \frac{\partial a}{\partial y} \right) = \frac{\phi^2 f(a) b \sqrt{1 - \psi \ln b}}{1 + \frac{\beta Z}{\psi} [\sqrt{1 - \psi \ln b} - 1]} \quad (2)$$

$$195 \quad \frac{\partial b}{\partial \theta} = - \frac{f(a) b \sqrt{1 - \psi \ln b}}{1 + \frac{\beta Z}{\psi} [\sqrt{1 - \psi \ln b} - 1]} \quad (3)$$

196 Where, dimensionless gaseous and solid reactants concentration are  $a$  and  $b$ , the initial Thiele  
197 modulus is  $\phi$ , the main RPM parameter which is the initial pore size distribution's function of the  
198 calcined slab is  $\psi$ , and the product layer's diffusion resistance is  $\beta$ . The initial and boundary  
199 conditions of the above equations are expressed as:

$$200 \quad \theta = 0 \rightarrow b = 1 \quad (4)$$

$$201 \quad y = 0 \rightarrow \frac{\partial a}{\partial y} = 0 \quad (5)$$

$$202 \quad y = 1 \rightarrow \frac{\partial a}{\partial y} = \frac{Sh}{\delta} (1 - a) \quad (6)$$

203 The local pellet porosity varies by time and described as (Bahrami et al. 2016, Moshiri et al. 2014):

$$204 \quad \frac{\varepsilon}{\varepsilon_0} = 1 - \frac{(Z - 1)(1 - \varepsilon_0)(1 - b)}{\varepsilon_0} \quad (7)$$

205 To relate the dimensionless effective pore diffusion and pellet porosity, following equation is used  
206 (Bahrami et al. 2016, Moshiri et al. 2014):

$$207 \quad \delta = \frac{D_e}{D_{e0}} = \left( \frac{\varepsilon}{\varepsilon_0} \right)^2 = \left[ 1 - \frac{(Z - 1)(1 - \varepsilon_0)(1 - b)}{\varepsilon_0} \right]^2 \quad (8)$$

208 The effective initial pore diffusion ( $D_{e_0}$ ) is calculated from molecular diffusion determined by the  
 209 Chapman-Enskog equation ( $D_{AM}$ ), and Knudsen diffusion equation based on the average pore size  
 210 ( $D_{AK}$ ), by the following equations (Bahrami et al. 2016, Liu & Wang 2019):

$$211 \quad \frac{1}{D_{e_0}} = \frac{1}{\varepsilon_0^2} \left( \frac{1}{D_{AM}} + \frac{1}{D_{AK}} \right) \quad (9)$$

$$212 \quad D_{AM} = \frac{1.859 \times 10^{-3} T^{1.5} \sqrt{\frac{1}{M_1} + \frac{1}{M_2}}}{p \sigma_{12}^2 \Omega} \quad (10)$$

$$213 \quad D_{AK} = \frac{2r_{av}}{3} \sqrt{\frac{8R_g T}{\pi M_A}} \quad (11)$$

214 The main parameters of RPM is computed using the PSD curve by the following equations  
 215 (Bahrami et al. 2016):

$$216 \quad V_p = \int_0^\infty v_0(r) dr \quad (12)$$

$$217 \quad \varepsilon_0 = \frac{V_p}{V_p + \frac{1}{\rho_B}} \quad (13)$$

$$218 \quad r_{av} = \frac{1}{V_p + \frac{1}{\rho_B}} \int_0^\infty v_0(r) r dr \quad (14)$$

$$219 \quad S_0 = \frac{2}{V_p + \frac{1}{\rho_B}} \int_0^\infty \frac{v_0(r)}{r} dr \quad (15)$$

$$220 \quad L_0 = \frac{1}{\pi(V_p + \frac{1}{\rho_B})} \int_0^\infty \frac{v_0(r)}{r^2} dr \quad (16)$$

221 
$$\psi = \frac{4\pi L_0(1 - \varepsilon_0)}{S_0^2} \quad (17)$$

222 The resulting structural parameters for the calcinated  $\text{Na}_2\text{CO}_3$  pellet from  $\text{NaHCO}_3$  are given in  
223 Table 1.

224 The conversion of slab pellet can be determined as follows (Bahrami et al. 2016, Moshiri et al.  
225 2014):

226 
$$X(\theta) = 1 - \int_0^1 b(y, \theta) dy \quad (18)$$

227 In this study, the finite element method is used for solving the coupled nonlinear partial differential  
228 equations of RPM.

229

## 230 **4. Results and Discussion**

### 231 **4.1 TG and Conversion-Time Results**

232 Typical experimental TG curves of sodium bicarbonate calcination as well as  $\text{Na}_2\text{CO}_3$  reaction  
233 with  $\text{SO}_2$  at 150 and 200 °C are presented in Figs. 4 and 5. As mentioned pictures show, the first  
234 stage were heating of sample pellet under zero air stream to reach the specified reaction  
235 temperatures. Through this calcination step, sample weight diminished and porosity of the pellet  
236 increased. So a high porous  $\text{Na}_2\text{CO}_3$  pellet was produced due to release of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  which  
237 was the reason for about 37% weight loss of initial sample weight. In the next stage, the stream  
238 was shifted to a combination of zero air and predefined  $\text{SO}_2$  concentration. As a result, the sample  
239 weight increased due to the sulfation reaction at isothermal condition of TG. During the reaction,  
240 the slope of TG curve decreased gradually because of the product layer's thickness increasing.

### 241 **4.2 Concentration Dependency Determination**

242 To determine the best reaction's order, several experiments with  $\text{SO}_2$  concentrations of 0.13, 0.33,  
243 0.66, and 1.12 vol% were carried out at 150 °C. So, the conversion-time data are plotted in Fig. 6.  
244 According to this figure, the conversion increased by raising  $\text{SO}_2$  mole fraction. As expected, the

245 pore diffusion and surface reaction controlled the overall rate during the initial stages, while in the  
 246 next slower stages the reaction rate controlled by product layer diffusion.

247 Now, the RPM equations were solved by considering  $\delta = b = 1$  at zero time to determine the initial  
 248 conversion-time slopes. Therefore, equation 1 can be simplified to (Bahrami et al. 2016, Moshiri  
 249 et al. 2014, Rashidi et al. 2013):

$$250 \quad \frac{\partial}{\partial y} \left( \frac{\partial a}{\partial y} \right) = \phi^2 f(a) \quad (19)$$

251 The dimensionless gas concentration profile,  $F(y)$ , inserted in equation 2 and integrated to:

$$252 \quad b_{\theta \rightarrow 0} = 1 - F(y)\theta \quad (20)$$

253 As a result, conversion at initial time for a slab pellet by using equation 20 and 18 was obtained as  
 254 follows:

$$255 \quad X_{\theta \rightarrow 0} = \int_0^1 F(y)\theta dy \quad (21)$$

256 The following equation by differentiation of equation 21 at initial time was obtained:

$$257 \quad \left[ \frac{dX}{d\theta} \right]_{\theta \rightarrow 0} = \int_0^1 F(y) dy \quad (22)$$

258 The dimensionless time was replaced in equation 22 as following (Bahrami et al. 2016, Moshiri et  
 259 al. 2014, Rashidi et al. 2013):

$$260 \quad I = \frac{C_{B0}(1 - \varepsilon_0)}{S_0 \int_0^1 F(y) dy} \left[ \frac{dX}{dt} \right]_{t \rightarrow 0} = k_s C_{Ab}^n \quad (23)$$

261 In equation 19,  $f(a)$  is the power law or fractional concentration dependency. To solve these  
 262 equations, the numerical analysis with iteration procedure was used. In this study, (I) was plotted  
 263 versus  $(C_{Ab}^n)$  for reaction order between 0.89 and 1.15. The highest regression coefficient was  
 264 observed in the fractional form. Furthermore,  $K_{ad}$  in the denominator was set to get the best results.

265 
$$f(a) = \frac{a}{1 + K_{ad} C_{Ab} a} \quad (24)$$

266 The results are summarized in Table 2. It is clear from this table, that the best regression coefficient  
 267 is related to fractional concentration dependency. Because of the low SO<sub>2</sub> concentrations  
 268 ( $1 \gg K_{ad} C_{Ab} a$ ), the reaction can be assumed first order.

### 269 4.3 Rate Constant Estimation

270 The effect of temperature (in the range of 100-250 °C) on Na<sub>2</sub>CO<sub>3</sub> reaction with constant (0.66  
 271 vol%) SO<sub>2</sub> concentration is shown in Fig. 7. Conversion improved by elevating temperature owing  
 272 to increasing the reaction rate. However, conversion decreases above 275 °C owing to the product  
 273 layer's sintering. The rate constant can be evaluated from the following equation for n=1 (Bahrami  
 274 et al. 2016):

275 
$$\left[ \frac{dX}{dt} \right]_{t \rightarrow 0} = \frac{k_s S_0 C_{Ab}}{C_{B0} (1 - \varepsilon_0)} \left[ \frac{\tanh\left(\frac{L_0}{2} \sqrt{\frac{k_s S_0}{\nu_B D_{e0}}}\right)}{\frac{L_0}{2} \sqrt{\frac{k_s S_0}{\nu_B D_{e0}}}} \right] \quad (25)$$

276 The calculated rate constants of Na<sub>2</sub>CO<sub>3</sub> reaction with 0.66 vol% SO<sub>2</sub> at different temperatures are  
 277 reported in Table 3. The frequency factor and activation energy can be evaluated by the Arrhenius  
 278 plot that is presented in Fig. 8. So, the rate constant was described as follows:

279 
$$k_s = 1.8 \times 10^{-2} \exp\left(\frac{-22486.04}{RT}\right) \quad (26)$$

### 280 4.4 Product Layer Diffusion Estimation

281 To obtain the  $D_p$  suitable values at various temperatures, the RPM conversion-time curves were  
 282 plotted by equations 2 and 3 numerically solving and plots was matched with the experimental  
 283 data. The upward and downward shifts in model conversion-time profiles are gained by higher and  
 284 lower  $D_p$  values, respectively.

285 Table 4 presents the essential parameters for RPM model at 150 °C. In this table, the low value of  
 286 Thiele modulus illustrates that the system is not completely controlled by diffusion, and the

287 accuracy of rate constants is appropriate. Fig. 9 shows a successful comparison between RPM  
288 predictions and experimental conversion-time profile at various operating temperatures. As  
289 demonstrated in this figure, simulation results predicts experimental data with good agreement.

290 Table 5 presents the appropriate  $D_p$  values. It is obvious that the  $D_p$  increases with temperature.  
291 The diffusion coefficient's Arrhenius plot is illustrated in Fig. 10. The frequency factor and  
292 apparent activation energy were found by regression on this diagram between 100-250 °C. Thus,  
293 the product layer diffusion is described as a function of temperature with the following expression:

$$294 \quad D_p = 3 \times 10^{-15} \exp\left(\frac{-23354.03}{RT}\right) \quad (27)$$

295

## 296 **5. Conclusion**

297 In this study, the kinetics of sulfur dioxide removal reaction by  $\text{Na}_2\text{CO}_3$  was comprehensively  
298 carried out by RPM. An isothermal TG was employed for experiments between 100-250 °C and  
299 0.13-1.12 vol%  $\text{SO}_2$ . The RPM as the most sophisticated mathematical model was applied to  
300 generate kinetic parameters of  $\text{SO}_2$  reaction by  $\text{Na}_2\text{CO}_3$ . The RPM considers solid reactant PSD,  
301 structural changes, solid reactant pore diffusion, and resistance of product layer. Nitrogen  
302 adsorption and mercury porosimetry methods were utilized to plot the complete PSD of the sample.  
303 The reaction relation with concentration and temperature were investigated by initial slopes  
304 procedure. As a result, the first-order concentration relationship can express the kinetics of the  
305 reaction with activation energy of 22.5 kJ mol<sup>-1</sup>. In addition, diffusion coefficients through product  
306 layer were specified. RPM predictions follows experimental data with a good agreement. Finally,  
307 industrial low temperature FGD plants can be designed by the obtained kinetic parameters.

308

## 309 **6. Nomenclature**

$a = C_A/C_{Ab}$  Dimensionless gas concentration

$b = C_B/C_{B0}$  Dimensionless solid concentration

$C_A$	Gaseous reactant concentration in the pellet, $\text{kmol m}^{-3}$
$C_{Ab}$	Bulk gas concentration, $\text{kmol m}^{-3}$
$C_B$	Solid reactant concentration, $\text{kmol m}^{-3}$
$C_{B0}$	Initial solid reactant concentration, $\text{kmol m}^{-3}$
$D_{AK}$	Knudsen diffusivity, $\text{m}^2 \text{s}^{-1}$
$D_{AM}$	Molecular diffusivity of gas A in the pellet, $\text{m}^2 \text{s}^{-1}$
$D_e$	Effective diffusivity of gas A in the pellet, $\text{m}^2 \text{s}^{-1}$
$D_{e0}$	Initial effective diffusivity of gas A in the pellet, $\text{m}^2 \text{s}^{-1}$
$D_p$	Effective diffusivity of gas A in the product layer, $\text{m}^2 \text{s}^{-1}$
$k_m$	External mass transfer coefficient, $\text{m s}^{-1}$
$k_s$	Surface rate constant, $\text{m s}^{-1}$
$K_{ad}$	Adsorption constant, $\text{m}^3 \text{kmol}^{-1}$
$L$	Thickness of the pellet, m
$L_0$	Pore length per unit volume, $\text{m}^{-2}$
$M_B$	Molecular weight of solid reactant, $\text{kg kmol}^{-1}$
$M_D$	Molecular weight of solid product, $\text{kg kmol}^{-1}$
$n$	Reaction order
$r$	Pore radius, m
$\bar{r}$	Average pore radius of the pellet, m
$R^2$	Correlation coefficient
$R$	Gas constant, $\text{J K}^{-1} \text{mol}^{-1}$
$S_0$	Reaction surface area per unit volume, $\text{m}^{-1}$

$Sh = \frac{k_m L}{2D_{AM}}$	Sherwood number for external mass transfer
$t$	Time, s
$U_0(r)$	Pore volume distribution function, $m^2 \text{ kg}^{-1}$
$V_p$	Total pore volume, $m^3 \text{ kg}^{-1}$
$X(\theta)$	Solid conversion at each time
$y=2z/L$	Dimensionless position in the pellet
$z$	Distance from the centre of the pellet, m
$Z$	Ratio of molar volume of solid product to solid reactant
$\beta = 2k_s(1-\varepsilon_0)/(\nu_B D_p S_0)$	Product layer resistance
$\mathcal{E}$	Pellet porosity
$\varepsilon_0$	Initial pellet porosity
$\delta = \frac{D_e}{D_{e0}}$	Variation ratio of the pore diffusion
$\theta = k_s S_0 C_{Ab}^n t / [C_{B0}(1-\varepsilon_0)] = t / \tau$	Dimensionless time
$V_B$	Stoichiometric coefficient of the solid reactant
$V_D$	Stoichiometric coefficient of the solid product
$\rho_B$	True density of the solid reactant, $\text{kg m}^{-3}$
$\rho_D$	True density of the solid product, $\text{kg m}^{-3}$
$\phi = (L/2)(k_s S_0 C_{Ab}^{n-1} / \nu_B D_{e0})^{1/2}$	Thiele modulus for the pellet
$\Psi$	Main RPM parameter

310 **7. Declarations**

311 **Ethics approval and consent to participate:** Not applicable

312 **Consent for publication:** Not applicable

313 **Availability of data and materials:** The datasets used and/or analyzed during the current study are  
314 available from the corresponding author on reasonable request.

315 **Competing interests:** The authors declare that they have no competing interests.

316 **Funding:** No funding was received for conducting this study.

317 **Authors' contributions:** Habib Ale Ebrahim is supervisor of this study. Iman Omidi acquired the data. All  
318 authors read and approved the final manuscript.
