**Version of Record:** A version of this preprint was published at International Journal of Chronic Obstructive Pulmonary Disease on September 1st, 2020. See the published version at <https://doi.org/10.2147/COPD.S266844>.

# Abstract

**Background:** We sought to determine whether circulating inflammatory biomarkers were associated with the frequent exacerbator phenotype in stable COPD patients i.e. those with two or more exacerbations in the previous year.

**Methods:** 88 stable, severe, COPD patients (4 females) were assessed for exacerbation frequency, pulmonary function, fraction of expired nitric oxide ( $F_{E}NO$ ); inflammatory variables were measured in venous blood. Logistic regression assessed associations between the frequent exacerbator phenotype and systemic inflammation.

**Results:** Compared with infrequent exacerbators, frequent exacerbators (n=10; 11.4%) had greater serum concentration (median (25<sup>th</sup>-75<sup>th</sup> quartile)) of serum amyloid A (SAA; 134(84-178) vs. 71(38-116) ng/ml; P=0.024), surfactant protein D (SP-D; 15.6(9.0-19.3) vs. 8.5(3.6-14.9) ng/ml; P=0.049) and interleukin-4 (IL-4; 0.12(0.08-1.44) vs. 0.03(0.01-0.10) pg/ml; P=0.001). SAA, SP-D and IL-4 were not significantly correlated with FEV<sub>1</sub> %predicted or FVC %predicted. After adjusting for sex, age, BMI, FEV<sub>1</sub>/FVC and smoking pack-years, only SAA remained independently associated with the frequent exacerbator phenotype (OR 1.49[1.09-2.04]; P=0.012). The odds of being a frequent exacerbator was 18-times greater in the highest SAA quartile ( $\geq 124.1$  ng/ml) than the lowest SAA quartile ( $\leq 44.1$  ng/ml) (OR 18.34[1.30-258.81]; P=0.031), and there was a significant positive trend of increasing OR with increasing SAA quartile (P=0.008). For SAA, the area under the receiver operating characteristic curve was 0.721 for identification of frequent exacerbators with an optimal SAA cut-off of 131.7 ng/ml.

**Conclusion:** In stable COPD patients, SAA was independently associated with the frequent exacerbator phenotype, suggesting that SAA may be a useful serum biomarker to inform progression or management in COPD.

## Background

Chronic obstructive pulmonary disease (COPD) is characterized by both an accelerated decline in lung function and periods of acute deterioration in symptoms, termed exacerbations. Exacerbations of respiratory symptoms in COPD are of major importance in terms of their prolonged detrimental effects on patients<sup>1</sup>. Frequent exacerbations contribute to long-term decline in lung function as well as to increased morbidity, decreased quality of life, and increased mortality of patients with moderate to severe COPD<sup>2-4</sup>. Some patients experience frequent exacerbations, and form a distinct clinical subgroup, the 'frequent exacerbator' phenotype, in contrast to patients who experience few exacerbations over time<sup>5</sup>. The frequent exacerbator phenotype is recognized as a major phenotype in patients with COPD and occurs across disease severities<sup>5</sup>.

Exacerbations are typically caused by respiratory tract infections<sup>6</sup>. During an acute exacerbation episode, the existing airway and systemic inflammation increase further<sup>7-9</sup>. Inflammatory mediators, cytokines

and chemokines are released into the circulation and induce recruitment of inflammatory cells into the lung parenchyma. Besides local damage to lung structures, activation of immune cells causes systemic inflammation with increases in acute phase proteins such as fibrinogen and C-reactive protein (CRP)<sup>7,10</sup>. The airways of frequent exacerbators are more inflamed than those with infrequent exacerbations, and frequent exacerbators have greater concentration of sputum interleukin-6 (IL-6) and - 8 (IL-8)<sup>11</sup>. In addition, during the exacerbation recovery period, sputum IL-6 and serum CRP are greater in the frequent exacerbator phenotype<sup>12</sup>, consistent with their greater baseline inflammatory state. In the post-exacerbation recovery period, greater serum concentration of inflammatory mediators, such as CRP, are associated with a shorter time until the next exacerbation<sup>12</sup>. As a result, CRP has been proposed as a predictive biomarker for COPD exacerbation<sup>13</sup>.

Similar to CRP, serum amyloid A (SAA) is an acute phase inflammatory biomarker, and is strongly associated with COPD exacerbations<sup>14</sup>. Bozinovski et al<sup>14</sup> studied stable and exacerbating COPD patients, and found that SAA was four-fold greater in patients experiencing a severe acute COPD exacerbation. They also identified that the increase in SAA was a more sensitive indicator of acute COPD exacerbation than CRP alone or in combination with dyspnea<sup>14</sup>.

SAA is a family of proteins that form a major component of the acute-phase inflammatory response and, like CRP, is synthesized mainly in the liver in response to infection, inflammation, injury, or stress<sup>15</sup>. Considering that SAA is a sensitive marker of an acute inflammatory state, we aimed to determine the association between the frequent exacerbator phenotype of COPD and SAA concentration in the stable state of COPD. We hypothesized that greater SAA is associated with the frequent exacerbator phenotype in COPD and that the relationship is stronger than for other markers of inflammation.

## Methods

### Patient population

This cross-sectional study was conducted at the First Affiliated Hospital of Guangzhou Medical University. Patients with severe to very severe COPD (GOLD [Global Initiative for Chronic Obstructive Lung Disease] spirometry stages 3–4)<sup>16</sup>, were recruited during their stable state. Exclusion criteria included a COPD exacerbation within the previous 4 weeks, lung cancer, bronchiectasis, pneumoconiosis or other restrictive ventilatory dysfunction and chronic systemic inflammatory conditions. Information collected included medical and smoking history, exacerbation frequency, pulmonary function and fraction of expired nitric oxide ( $F_{E}NO$ ). Venous blood was collected and serum was assessed for inflammatory variables. The study protocol was approved by the Medical Ethics Review Committee of the First Affiliated Hospital of Guangzhou Medical University and all subjects provided written informed consent.

### Subgroups

Moderate and severe exacerbations were captured by a review of medical records. Moderate exacerbations were defined as an acute worsening of respiratory symptoms treated by antibiotics and/or oral steroids and severe exacerbations as a worsening of respiratory symptoms requiring hospitalization or emergency room visit.<sup>16</sup>. Frequent exacerbations were defined as two or more exacerbations in the previous year<sup>16,17</sup>. Subjects were divided into two groups: 1) “frequent exacerbators”, who experienced two or more moderate or severe exacerbations in the 12 months prior to study enrollment; 2) “infrequent exacerbators”, who had one or no exacerbations in the 12 months prior to study enrollment.

## Blood Sampling And Measurement Of Inflammatory Markers

Venous blood samples were collected from subjects by venipuncture in plain tubes. The samples were centrifuged immediately at 2,500 rpm for 15 minutes at room temperature and the serum fraction was collected and frozen at -80°C pending subsequent procedures. The concentration of SAA (R&D, #DY3019-05), SP-D (R&D, #DSFPD0), PRG4 (SAB, #EK2481), LTB4 (Abcam, #ab133040), MMP-8 (R&D, #DMP800), MMP-9 (Bioscience, #85-BMS2016-2) were measured in the serum by an enzyme-linked immunosorbent assay (ELISA). The concentration of GM-CSF, IL-1 $\beta$ , IL-4, IL-6 and IL-8 were measured using human cytokine V-PLEX validated immunoassay kit (Meso Scale Discovery, Gaithersburg, MD).

## Pulmonary Function Testing

Spirometry was performed by using a portable spirometer (Carefusion MasterScreen Pneumo, Germany) before, and 20 minutes after, inhalation of 400  $\mu$ g of short-acting  $\beta_2$ -agonist (albuterol) in accordance with the ERS/ATS recommendations<sup>18</sup>. Spirometric data were reviewed and graded by a quality control software (Sentrysuite V.2.3). Predicted values were calculated according to the use of the reference values from the European Coal and Steel Community (1993) and the application of conversion factors for Chinese adults (male: 0.95, female: 0.93)<sup>19</sup>.

## Fractional Exhaled Nitric Oxide (fno)

F<sub>E</sub>NO was measured by using the NIOX system (NioxMino® F<sub>E</sub>NO analyzer, Aerocrine, Sweden) in accordance with ATS/ERS recommendations<sup>20</sup>. F<sub>E</sub>NO was measured before

spirometry and measured three times, with differences  $\leq$ 10% indicating acceptable variance. The mean value of three measurements is reported.

## Statistical analysis

Data were expressed as mean  $\pm$  standard deviation (SD) or median (25th -75th quartiles) or as percentage. Univariate analyses included independent-samples Student's t or Mann-Whitney test for continuous variables or chi-square test or Fisher's exact test for categorical variables between two groups, as appropriate. SAA concentration was divided in quartiles. Relationships among frequent exacerbator phenotype (dependent variable) and clinical data, spirometric values, inflammatory variables and SAA (square root (sqrt) transformed) (independent variables), were assessed by logistic regression. A multivariable logistic regression model was adjusted for age, sex, smoking pack-years, body mass index and FEV<sub>1</sub>/FVC. The trend for linearity between the odds ratio (OR) and SAA quartiles was estimated by logistic regression including the median of each SAA quartile as a continuous variable. The optimal SAA cut-off point (highest sum of sensitivity and specificity) to identify frequent exacerbators was selected using receiver operating characteristic (ROC) analysis. Correlations between inflammatory variables and pulmonary function were assessed by Spearman correlation. All statistical analyses were performed using SPSS (IBM SPSS V.25.0, Armonk, NY, USA). Statistical significance was set at  $P < 0.05$ . Figures were created using GraphPad Software (GraphPad Prism V.8.0 for Windows, San Diego, California USA).

## Results

### Patient characteristics

A total of 88 patients were enrolled. Patient characteristics are shown in Table 1. Overall, the group was predominantly male (96%), aged  $64 \pm 7$  years with severe or very severe COPD (FEV<sub>1</sub>  $38 \pm 9\%$  predicted). Ten (11.4%) patients were frequent exacerbators (3 (2–4) exacerbations in the previous 12 months), while 78 (88.6%) were infrequent exacerbators (0 (0–1) exacerbations in the previous 12 months). Frequent exacerbators had a significantly greater CAT score (13 (9–16) vs. 9 (6–12);  $P = 0.028$ ), greater mMRC dyspnea scale (2 (1–3) vs. 1 (1–2);  $P = 0.001$ ), a lower post-bronchodilator (BD) FVC ( $2.01 \pm 0.40$  vs.  $2.66 \pm 0.60$  L;  $P = 0.001$ ), and lower post-BD FVC %predicted ( $58.3 \pm 10.9$  vs.  $75.9 \pm 15.8\%$  predicted;  $P = 0.001$ ). There was no significant difference between the two groups in age, sex, BMI, current smoker status, smoking pack years, post-BD FEV<sub>1</sub>, post-BD FEV<sub>1</sub> %predicted or post-BD FEV<sub>1</sub>/FVC (Table 1).

Table 1  
Patient characteristics

Variable	Total (n = 88)	Infrequent Exacerbators (n = 78)	Frequent Exacerbators (n = 10)	P Value
Age, year	64.2 ± 7.3	63.9 ± 7.4	66.5 ± 6.3	0.288
Male, n (%)	84 (96%)	75 (96%)	9 (90%)	0.388
BMI, kg/m <sup>2</sup>	21.5 ± 3.7	21.5 ± 3.7	21.4 ± 3.5	0.970
Post-BD FVC, L	2.59 ± 0.62	2.66 ± 0.60	2.01 ± 0.40	0.001
Post-BD FVC %predicted	73.9 ± 16.3	75.9 ± 15.8	58.3 ± 10.9	0.001

mMRC dyspnea scale	1 (1–2)	1 (1–2)	2 (1–3)	0.001
Data mean ± SD or median (25th–75th interquartile range) or percentage. Infrequent exacerbators are defined as patients with 1 or fewer exacerbations in the previous year. Frequent exacerbators are defined as patients with 2 or more exacerbations in the previous year. Abbreviations: BMI = body mass index; BD = bronchodilator; FEV <sub>1</sub> = forced expiratory volume in 1 second; FVC = forced vital capacity; FEV <sub>1</sub> %pred = percentage of predicted FEV <sub>1</sub> ; FVC%pred = percentage of predicted FVC; CAT = COPD assessment test; mMRC = modified Medical Research Council dyspnea scale.				

## Inflammatory Variables In Groups Based On Exacerbation Frequency

SAA was significantly greater in frequent exacerbators compared to infrequent exacerbators ( $P = 0.024$ ) (Table 2; Fig. 1, A). Similarly, SP-D ( $P = 0.049$ ; Fig. 1, B) and IL-4 ( $P = 0.001$ ; Figs. 1, C) concentrations were significantly greater in frequent exacerbators compared infrequent exacerbators (Table 2). There was no significant difference between the two groups in other inflammatory variables including IL-1 $\beta$ , IL-6, IL-8, CRP, LTB4, GM-CSF, F<sub>E</sub>NO, MMP8, MMP9 and PRG4 (Table 2).

Table 2  
Inflammatory variables in groups based on exacerbation frequency

Variable	Infrequent Exacerbators (n = 78)	Frequent Exacerbators (n = 10)	P Value
SAA (ng/ml)	71 (38–116)	134 (84–178)	0.024
SP-D (ng/ml)	8.46 (3.64–14.91)	15.57 (9.00–19.27)	0.049
IL-1 $\beta$ (pg/ml)	0.09 (0.01–0.19)	0.05 (0.01–0.26)	0.496
IL-4 (pg/ml)	0.03 (0.01–0.10)	0.12 (0.08–1.44)	0.001
IL-6 (pg/ml)	0.70 (0.32–1.07)	0.60 (0.42–2.61)	0.854
IL-8 (pg/ml)	5.09 (4.22–6.53)	4.90 (3.85–6.30)	0.617
CRP (mg/dl)	0.21 (0.08–0.74)	0.20 (0.12–0.90)	0.533
LTB4 (ng/ml)	278 (166–354)	279 (162–333)	0.737
GM-CSF (pg/ml)	0.04 (0.01–0.14)	0.01 (0.00–0.13)	0.788
F <sub>E</sub> NO (ppb)	22.0 (16.3–31.0)	18.00 (14.5–27.5)	0.457
MMP8 (pg/ml)	681 (446–1136)	679 (457–2014)	0.604
MMP9 (ng/ml)	123 (81–182)	134 (74–156)	0.905
PRG4 (ng/ml)	54.2 $\pm$ 22.2	40.5 $\pm$ 23.1	0.101

Data median (25th–75th interquartile range) or mean  $\pm$  SD. Infrequent exacerbators are defined as patients with 1 or fewer exacerbations in the previous year. Frequent exacerbators are defined as patients with 2 or more exacerbations in the previous year. Abbreviations: SAA = Serum amyloid A; SP-D = Surfactant protein D; IL-1 $\beta$  = Interleukin-1 $\beta$ ; IL-4 = Interleukin-4; IL-6 = Interleukin-6; IL-8 = Interleukin-8; CRP = C-reactive protein; LTB4 = Leukotriene B4; GM-CSF = Granulocyte-macrophage colony-stimulating factor; F<sub>E</sub>NO = Fractional exhaled nitric oxide; MMP-8 = Matrix metalloproteinase-8; MMP-9 = Matrix metalloproteinase-9; PRG4 = Proteoglycan 4.

## Correlations Between Saa, Sp-d, Il-4 And Pulmonary Function

Table 3 shows Spearman correlation between SAA, SP-D, IL-4 and spirometric measures of pulmonary function. For these three inflammatory markers, there was no significant correlation with post-BD FVC %predicted, post-BD FEV<sub>1</sub> %predicted, and post-BD FEV<sub>1</sub>/FVC (Table 3).

Table 3  
The correlation between SAA, SP-D, IL-4 and pulmonary function

Variable	Post-BD FEV <sub>1</sub> %pred		Post-BD FVC%pred		Post-BD FEV <sub>1</sub> /FVC	
	R Value	P Value	R Value	P Value	R Value	P Value
SAA	-0.113	0.148	-0.145	0.090	0.023	0.416
SP-D	0.016	0.881	-0.033	0.759	0.074	0.495
IL-4	-0.077	0.503	-0.069	0.547	0.045	0.697

Abbreviations: BD = bronchodilator; FEV<sub>1</sub>%pred = percentage of predicted FEV<sub>1</sub>; FVC%pred = percentage of predicted FVC; SAA = Serum amyloid A; SP-D = Surfactant protein D; IL-4 = Interleukin-4.

**Tables**

## Association Between Saa And Frequent Exacerbations

In the univariate logistic regression models, SAA was significantly associated with frequent exacerbator status (OR 1.33; 95%CI 1.03–1.70; P = 0.027). SP-D, IL-4 and other inflammatory variables including IL-1 $\beta$ , IL-6, IL-8, CRP, LTB<sub>4</sub>, GM-CSF, F<sub>E</sub>NO, MMP8, MMP9, PRG4 were not significantly associated with frequent exacerbator status (Fig. 2, A). In the multivariable logistic regression model, adjusting for sex, age, BMI, Post-BD FEV<sub>1</sub>/FVC and smoking pack-years, SAA was independently associated with the frequent exacerbator phenotype (OR 1.49; 95%CI 1.09–2.04; P = 0.012) (Fig. 2, B).

## Associations Between Saa Quartiles And Frequent Exacerbations

The odds ratio for the association of frequent exacerbator status with quartiles of SAA concentration is presented in Fig. 3. After adjusting for sex, age, BMI, Post-BD FEV<sub>1</sub>/FVC and smoking pack-years, the hazard of frequent exacerbator status in the highest SAA quartile ( $\geq 124.1$  ng/ml) was 18 times that of the lowest SAA quartile ( $\leq 44.1$  ng/ml) (OR 18.34; 95%CI 1.30-258.81; P = 0.031). In categorical analysis, we found that a significant linear association between the OR for frequent exacerbator status and increasing SAA quartile (P value for trend = 0.008) (Fig. 3).

### Sensitivity and specificity of SAA to identify the frequent exacerbator phenotype

In ROC analysis, yielded an area under the curve (AUC) of 0.721 (95%CI 0.542–0.899) for the identification of frequent exacerbators. The optimal SAA to separate infrequent from frequent exacerbators was 131.7 ng/ml and corresponded to a sensitivity of 60.0% and specificity of 82.1% (Fig. 4).

## Discussion

The principal finding of this study was that the serum concentrations of SAA, SP-D and IL-4 were greater in COPD patients who experienced 2 or more exacerbations in the preceding year compared with those who did not. In addition, SAA, but not the other inflammatory biomarkers, was significantly associated with the frequent exacerbator phenotype after adjusting for potential covariates and was independent of spirometric measures of pulmonary impairment. We also found that the risk of frequent exacerbator status in the highest SAA quartile was 18 times of those in the lowest quartile, suggesting that SAA might be a good indicator of the frequent exacerbator phenotype in COPD. SAA = 131.7 ng/ml was optimal to separate infrequent from frequent exacerbators, to our knowledge using ROC analysis. Although the inflammatory biomarker SAA is known to be raised during an acute COPD exacerbation<sup>14</sup>, this is the first study to demonstrate an association of SAA with the exacerbation phenotype in stable phase of COPD. SAA may therefore be a useful biomarker to identify patients at risk of frequent exacerbations, to inform progression and to guide management of COPD.

Investigators have long sought a circulating biomarker that separates non-exacerbators from exacerbators. In the ECLIPSE trial, 2,138 COPD patients were followed for three years to determine predictors of exacerbations. None of the measured circulating biomarkers were independent predictors of exacerbation frequency. More recently, Gulati and colleagues reported a greater concentration of fibroblast growth factor 23 (FGF23) in frequent exacerbators compared with patients without frequent exacerbations<sup>21</sup>. In addition, these investigators showed that FGF23 is independently associated with frequent exacerbations, after adjusting for age, lung function, smoking and oxygen use<sup>21</sup>.

Previous studies showed that SAA is dramatically increased during acute phase of a COPD exacerbation, and that SAA is a sensitive biomarker for exacerbation severity in COPD patients<sup>14</sup>. Other studies showed increased circulating SAA concentration in COPD and other pulmonary diseases such as idiopathic pulmonary fibrosis (IPF)<sup>22-24</sup>. Formiga et al. reported that inspiratory muscle performance was considerably lower in COPD patients with greater SAA concentration<sup>23</sup>. In addition, SAA was greater in patients with IPF than in healthy controls<sup>22</sup>. Furthermore, serum levels of SAA and CRP together with other inflammatory markers (e.g. IL-6, IL-8, TNF- $\alpha$ , IP-10) were significantly greater in COPD patients experiencing an exacerbation than during remission and in healthy control subjects<sup>24</sup>.

Elevated SAA was reported in patients with cardiovascular disease where COPD was a comorbidity<sup>25</sup>. Since half of the deaths in COPD are associated with cardiovascular events, and the incidence of these events increases dramatically after each exacerbation<sup>26,27</sup>, and also because SAA is a good predictor of coronary artery disease as well as future cardiovascular events, SAA might be considered as a potential indicator of frequent exacerbation phenotype as well as an indicator of comorbid cardiovascular disease.

As well as acting as a biomarker for the frequent exacerbator phenotype during the stable phase of COPD, evidence suggests that SAA may mediate an acute COPD exacerbation<sup>14</sup>. SAA induces lung inflammation in COPD by promoting lung neutrophilia, which is activated by increasing expression of IL-

17a in  $\gamma\delta$ T cells<sup>28</sup>. In addition, SAA activates the NLRP3 inflammasome and elicits robust TLR2-, MyD88-, and IL-1-dependent pulmonary inflammation<sup>29</sup>. Consistent with this, SAA is found in the lungs and bronchoalveolar lavage fluid of smoke exposed COPD patients and endotoxin-challenged mice<sup>30,31</sup>.

In stable COPD patients we also showed that the circulating concentration of SP-D was greater in frequent exacerbators compared to infrequent exacerbators, although SP-D was not independently associated with exacerbation. Although no previous study compared the serum concentration of SP-D between frequent and infrequent exacerbators, the ECLIPSE study showed that SP-D significantly, although weakly, predicted exacerbation during the first year of follow-up<sup>17</sup>. SP-D is mainly produced by type II alveolar cells in the lung<sup>32</sup>, and is involved in regulating pulmonary surfactants, lipid homeostasis and innate immunity in order to protect the lungs from pathogens<sup>33-35</sup>. SP-D has many protective properties including anti-inflammatory and anti-oxidant functions<sup>34</sup> that associate with protection against the development of COPD<sup>36</sup>. SP-D knockout mice have large lungs with enlarged airspaces and activated macrophages; they develop progressive pulmonary emphysema and subpleural fibrosis in association with chronic inflammation<sup>37</sup>.

A major role of SP-D is to regulate antibody-independent immune responses against invading microorganisms<sup>38</sup>. Indeed, SP-D deficient mice are more susceptible to respiratory infections with *Pneumocystis carinii*, influenza, respiratory syncytial virus, and bacteria<sup>39-42</sup>. This is consistent with the observation that COPD patients with serum SP-D concentration greater than the 95th percentile of nonsmokers had an increased risk of exacerbation over the following 12 months<sup>43</sup>.

Our results showed no significant correlation between serum SP-D and spirometric lung function (FEV<sub>1</sub>%pred, FVC%pred, FEV<sub>1</sub>/FVC), which is consistent with several other studies<sup>43</sup>. The interpretation of association of serum SP-D and lung function is complicated in that serum SP-D is affected not only by lung synthesis, but also by increased leakage of SP-D from the COPD lung into the systemic circulation<sup>36</sup>. Nevertheless, in our study, SP-D was not as strongly (or independently) associated with the frequent exacerbator phenotype as SAA.

We also found serum IL-4 was significantly greater in frequent exacerbators, but regression analysis showed no significant independent correlation between IL-4 and exacerbator phenotype in our stable COPD patients. IL-4 is secreted by Th-2 lymphocytes which stimulate the proliferation of B lymphocytes to produce IgG and IgE, and to mediate humoral immunization<sup>44</sup>. To our knowledge this is the first study showing greater concentration of IL-4 in frequent than infrequent exacerbators. Previous studies showed that serum IL-4 is greater in COPD patients during an acute exacerbation compared with stable COPD and control groups<sup>45</sup>. Additionally, IL-4 concentration was dramatically increased in *Mycoplasma pneumoniae*-induced airway diseases, including those occurring in COPD patients<sup>46</sup>. These data suggest that Th2 secreted cytokines (e.g., IL-4) might play an important role in reducing inflammation. Based on this rationale, greater IL-4 in frequent exacerbators compared with infrequent exacerbators might indicate a protective role of Th2 lymphocytes and their secreted cytokines in balancing immune system function

during acute infection and exacerbation. On the other hand, increased concentration of IL-4 due to hyper-activated Th2 cells might increase the concentration of IgE immunoglobulin which leads to airway hyper-responsiveness in exacerbating COPD patients<sup>45</sup>. Despite this proposal, we did not find a correlation between IL-4 concentration and spirometric pulmonary function.

This study has limitations. We enrolled fewer frequent exacerbators than infrequent exacerbators. This might affect our ability to detect differences between the two groups. In addition, our study suffers from gender imbalance. The majority of our subjects were men (96%), limiting our ability to assert whether our findings also apply to women with COPD.

## **Conclusions**

This study demonstrated that serum SAA, SP-D and IL-4 concentration was greater in stable COPD patients who had 2 or more exacerbations in the previous year compared with those who experienced 1 or none. Further, SAA was significantly and independently correlated with the frequent exacerbator phenotype but not with spirometric indices of lung function. SAA should be considered as a potential biomarker of the frequent exacerbator phenotype in COPD. These findings provide new insights into the phenotyping COPD and may be a useful to inform management of COPD patients.

## **List Of Abbreviations**

<b>BMI</b>	<b>Body mass index</b>
BD	Bronchodilator
FEV <sub>1</sub>	Forced expiratory volume in one second
FEV <sub>1</sub> %pred	Percentage of predicted FEV <sub>1</sub>
FVC	Forced vital capacity
FVC%pred	Percentage of predicted FVC
CAT	COPD assessment test
mMRC	Modified Medical Research Council dyspnea scale
SAA	Serum amyloid A
SP-D	Surfactant protein D
IL-1 $\beta$	Interleukin-1 $\beta$
IL-4	Interleukin-4
IL-6	Interleukin-6
IL-8	Interleukin-8
CRP	C-reactive protein
LTB4	Leukotriene B4
GM-CSF	Granulocyte-macrophage colony-stimulating factor
F <sub>E</sub> NO	Fractional exhaled nitric oxide
MMP-8	Matrix metalloproteinases-8
MMP-9	Matrix metalloproteinases-9
PRG4	Proteoglycan 4
NLRP3	NLR family pyrin domain containing 3

## Declarations

## Acknowledgements

Results of this study have been presented at the American Thoracic Society 2020 annual conference. The authors would like to thank the investigators and patients at their investigative sites for their support of this study.

## Authors' contributions

NZ is the guarantor of this study. The study was conceived and designed by NZ,DZ,AA, HBR and RC.XS, HL, YP and LS contributed to patient recruitment. WZ,QY, XG, YZ and TL contributed to data acquisition. The data were analyzed by DZ. All authors contributed to the drafting of the manuscript and approved its publication.

## Funding

This work was funded unconditionally by National Key R&D Program of China (2018YFC1313600&2016YFC0901102); Local Innovative and Research Teams Project of Guangdong Pearl River Talents Program (2017BT01S155). The sponsors have no role in design, conduct, data interpretation of the study, and preparation, review or approval of this manuscript.

## Ethics approval and consent to participate

The clinical study was approved by the Medical Ethics Review Committee of the First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China. The reference number for the study is 2016-20. Informed consent about the study procedures were signed and obtained from all the subjects before the study.

## Availability of data and materials

The datasets used and analyzed during the current study are available from the corresponding author on reasonable request.

## Consent for publication

Not applicable.

## Competing interests

The authors declare that they have no competing interests.

## Figures

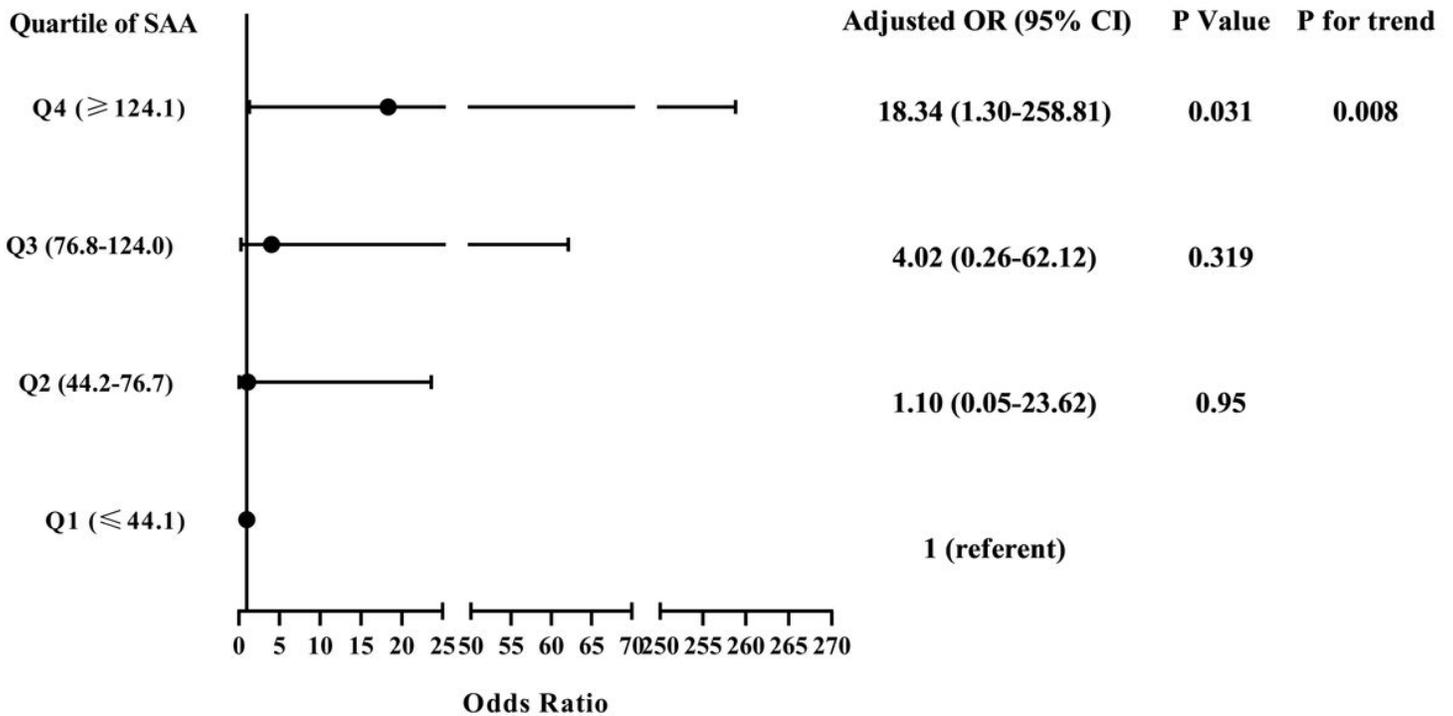

**Figure 1**

Comparison of SAA, SP-D and IL-4 concentration between frequent exacerbators and infrequent exacerbators. Frequent exacerbators (n=10) are defined as patients with 2 or more exacerbations in the previous year. Infrequent exacerbators (n=78) are defined as patients with 1 or none exacerbations in the previous year. (A) SAA concentration. (B) SP-D concentration. (C) IL-4 concentration. Statistical comparisons by Mann-Whitney test.

**Figure 2**

Odds ratio for variables associated with the frequent exacerbator phenotype (A) Univariate logistic regression models.(B)Multivariable logistic regression model adjusting for sex, age, BMI, FEV1/FVC and smoking pack-years. SAAwas square root (sqrt) transformed to normalize its distribution.

**Figure 3**

Associations between SAA quartiles and the frequent exacerbator phenotype Multivariable logistic regression model adjusting for sex, age, BMI, FEV1/FVC and smoking pack-years. SAA concentration was divided in quartiles: Q1,  $\leq 44.1$  ng/ml; Q2, 44.2-76.7 ng/ml; Q3, 76.8-124.0 ng/ml; Q4,  $\geq 124.1$  ng/ml. Linear association between OR and SAA quartile was assessed by P for trend using logistic regression model including the median of each SAA quartile as a continuous variable.

# ROC curve

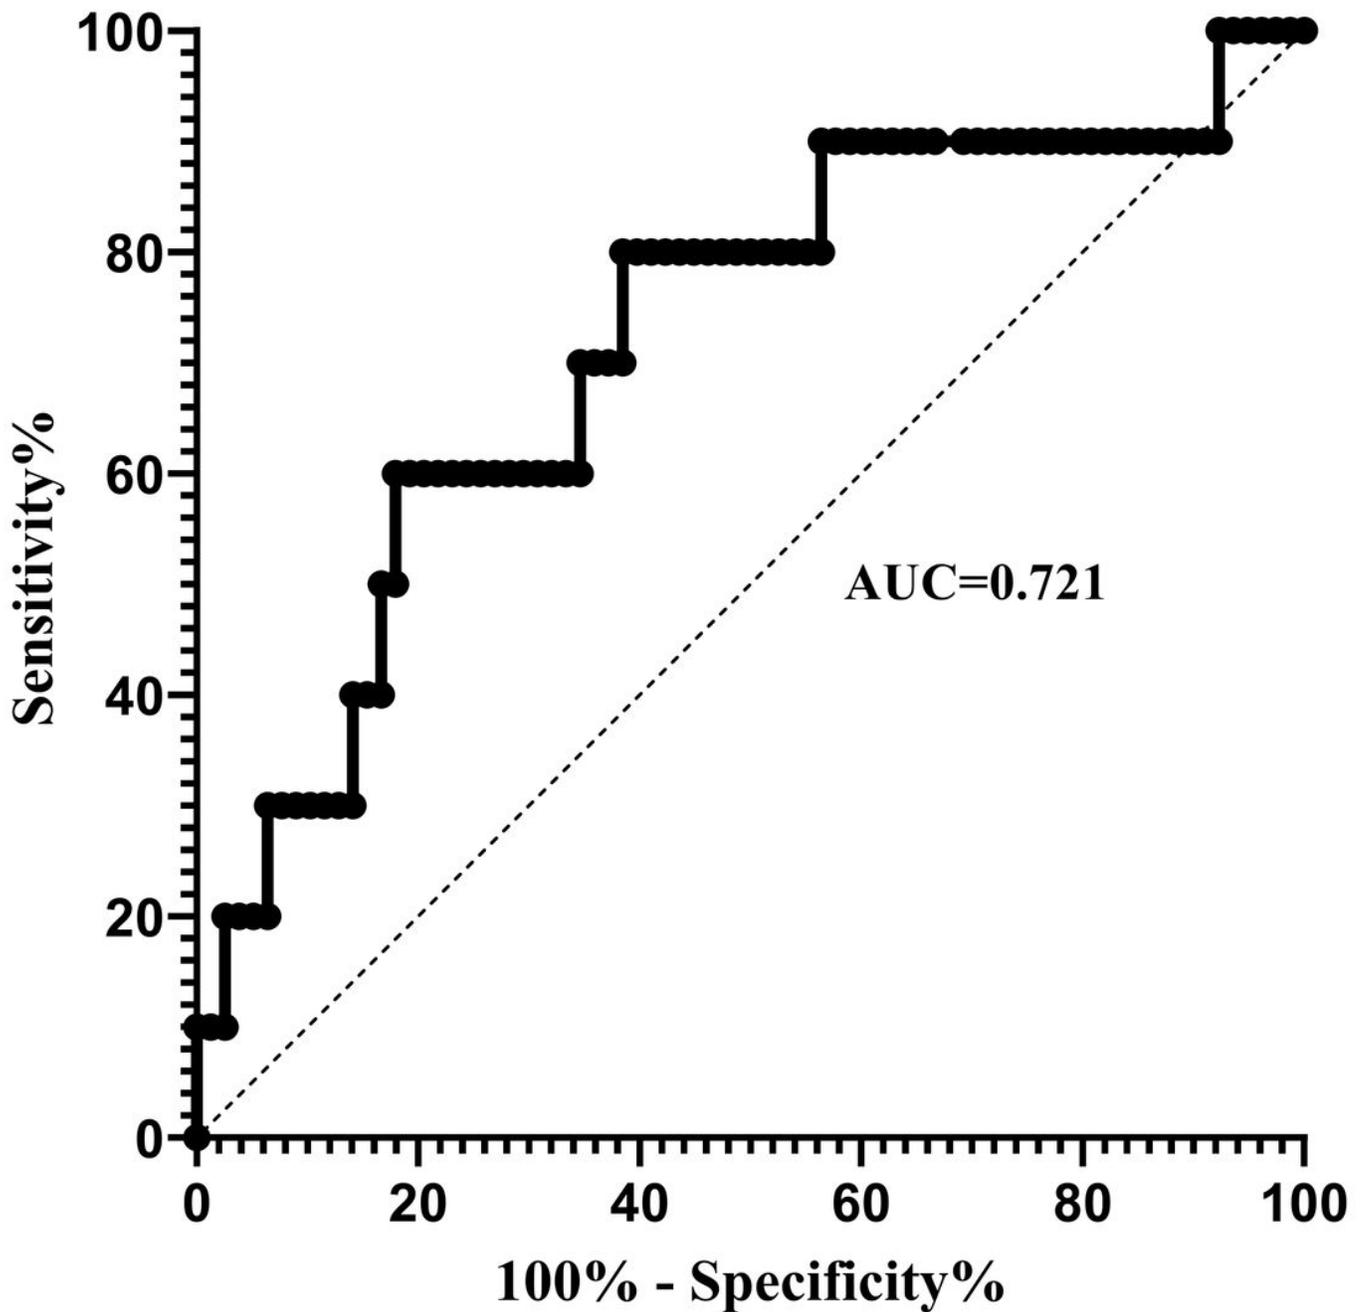

Figure 4

Receiver operating characteristic (ROC) for identification of the frequent exacerbator phenotype by serum amyloid A (SAA) ROC analysis yielded an area under the curve (AUC) of 0.721 (95%CI 0.542–0.899) for the identification of frequent exacerbators. The optimal cut-off separating infrequent from frequent exacerbators of SAA=131.7 ng/ml corresponded to a sensitivity of 60.0% and specificity of 82.1%.
