Abstract

Background: Small bowel volvulus (SBV) is a benign gastrointestinal surgical condition in which there is a torsion of all or parts of a segment of small bowel on its mesenteric axis. It has been contributed significant burden of surgical emergency as cause of small bowel obstruction in developing countries. The main objective this study was to explore clinical and epidemiological profile of Small bowel volvulus in Northcentral Ethiopia

Method: The study was conducted at Debre Tabor General Hospital, South Gondar in Northcentral Ethiopia. The medical records of patients with a discharge diagnosis of small bowel volvulus were reviewed. The patients were seen for a 4year period from Jan1, 2016-Dec31, 2019. The study was hospital-based retrospective cross-sectional and data were collected with a standardized structure questioner tool. The collected data checked for any inconsistency, code, and enter SPSS version 23 for data processing and analysis. Descriptive analyses were represented as frequency, percent, mean \pm standard deviation for normal distribution, and Median \pm Interquartile range for skewed data. Cross tabulation analysis was done for risk factors contributed for mortality and morbidity of SBV.

Result: There were 148 patients with Small bowel volvulus as a cause of small bowel obstruction was admitted within four years. The annual occurrence rate of SBV was 35cases per year. Small bowel volvulus represented 59% of small bowel obstruction and 36.3% of bowel obstruction. The majority of SBV were males (N=125, 84.5%) and females were (N=23, 15.5%). The age ranged from 15-78years. The mean age was $41.14 \pm (SD=15.4)$. The most common clinical presentation was abdominal pain 98% and vomiting 91.2%. The median time of hospital stay was 5 days (\pm IQR=2). The mean duration of illness before hospital admission was 2days (\pm SD=1.4) and median was 1 day (\pm IQR=2). The morbidity rate was 5.4% (N=8) and the mortality rate was 3.4 % (N=5)

Conclusion: Annual occurrence of SBV was 37 cases per year. The prevalence of SBV was 59% of small bowel obstruction and 36.3% of bowel obstruction respectively.

Background

The origin of the word volvulus is derived from the Latin word “volvere” which means turn or roll [1]. Small bowel volvulus (SBV) is a benign gastrointestinal surgical condition in which there is a torsion of all or parts of a segment of small bowel on its mesenteric axis [2]. Small bowel volvulus is a rare cause of surgical emergency in the western and the USA while it is commonly found in Africa, India, and Iran [3]. Small bowel volvulus can be Neonatorm volvulus, primary or secondary according to the cause. The mechanism and underlying cause of primary SBV has not been well illustrated but the presumed factors include unusual mobility of small bowel, laxity of abdominal wall, physical exercise, absence of mesenteric fat, constipation or diarrhea, and the unusual length of small bowel segment[2–5]. Secondary SBV occurs in the presence of acquired underlying conditions such as post-op adhesion, tumors, pregnancy, diverticular disease, and bands [2] while Neonatorm volvulus is due to malrotation of bowel

and defective fixation of mesentery [3]. Small bowel volvulus is a rare cause of mechanical small bowel obstruction. The incidence rate of SBV is high (24-60 per 100,000 populations) in Africa, Asia and Middle Eastern while low (1.7–5.7 per 100,000 populations) in western [6]. The overall mortality rate of SBV varies from 10–38%, viable bowel 3–13% in western and 20–25% in Africa and Indian. The mortality rate of gangrenous bowel has been reported in a range of 20–100% [7]

Methods

Study area, period and Design

The study was conducted at Debre Tabor General Hospital, South Gondar in Northcentral Ethiopia. The medical records of patients with a discharge diagnosis of small bowel volvulus were reviewed. The patients were seen for a 4 year period from Jan1, 2016-Dec31, 2019. The study was hospital-based retrospective cross-sectional and data were collected with a standardized structure questioner tool. The Question tool contained demography, clinical presentation, and duration of illness, procedures and intraoperative findings, postoperative complications, and management outcome. All patients from age 15 years and above with clinical or/and radiological diagnosis of Small bowel volvulus which managed with conservatively and /or operatively or died due to confirmed Small bowel volvulus was included while paralytic Ileus (functional obstruction) and age below 15 years were excluded from the study. The hospital provides clinical service for approximately 900 inpatient and 80,000 outpatients in a year that comes from the catchment area of the population around 3.5 million.

Data collection and analysis

Data collected with a structured questionnaire that is developed by the English language and translated to the Amharic language. The tool was prepared after reviewed different literature and pretested before data collection. The collected data checked for any inconsistency, code, and enter SPSS version 23 for data processing and analysis. Normal distribution was evaluated with the Q-Q plot test and histogram diagram. Descriptive analyses were represented as frequency, percent; mean \pm standard deviation for normal distribution, and Median \pm Interquartile range for skewed data. Cross tabulation analysis was done for risk factors contributed for mortality and morbidity of SBV.

Ethical consideration

Ethical Review Committee of Debretabor University was approved and collection started after approval of the proposal. The confidentiality and privacy of patients maintained during data collection. The data collected retrospectively from the medical chart and consent from patients is not needed

Results

There were 148 patients with Small bowel volvulus as a cause of small bowel obstruction was admitted within four years. Small bowel volvulus represented 59% of small bowel obstruction and 36.3% of bowel obstruction. The majority of SBV were males (N = 125, 84.5%) and females were (N = 23, 15.5%). The

majority of SBV patients were rural residents (N = 121, 81.8%) and urban residents were (N = 27, 18.2%). The age ranged from 15–78 years. The mean age was $41.14 \pm (SD = 15.4)$ (Table 2)

Table 2
The Demographic and Characteristics of the Patients
Small bowel volvulus in Debre Tabor Hospital,
Northcentral Ethiopia, 2020

Item		Frequency	Percent (%)
Age N = 148	15–25	28	18.9
	26–35	34	23.0
	36–45	33	22.3

	Female	23	15.5
Residence N = 148	Rural	121	81.8
	Urban	27	18.2

The most common clinical presentation was abdominal pain 98% and vomiting 91.2%. Most of the patients presented within 48hr (67.6%) and 48-72hr (19.6%). The mean of hospital stay was 5.3days ($\pm SD = 2.9$) and ranged from 1-18 day. The median time of hospital stay was 5 days ($\pm IQR = 2$). The mean duration of illness before hospital admission was 2days ($\pm SD = 1.4$) and median was 1 day ($\pm IQR = 2$). Majority of the patient respond for conservative treatment with NPO, NGT decompression and fluid resuscitation (43.2%). The most common procedure for non-respond for conservative measures were Derotation and Milking for 39.9% and Primary resection and anastomosis for 16.2%(Table 3). The morbidity rate was 5.4% (N = 8) and the Mortality rate was 3.4%(N = 5) (Table 3& 4). Wound infection was found as most complication.

Cross tabulation analysis showed morbidity rate of SBV was more likely female 8.7%vs4.8%, common in age > 40 years 5.8%vs5.1%, urban 7.4%vs. 5%, Hospital stay > 7 days 24%vs1.6

%, patients presented 72–96 hrs. 12.5% ,as compared less than 48hr 5%, gangrenous SBV 20%vs.2.4% ,emergency procedure 9.6% vs0% conservative and primary resection and analysis16%vs Derotation and Milking

Cross tabulation analysis showed mortality of SBV was more likely common in age < 40 years 3.8%vs2.9%, urban 3.7%vs.3.3%, Hospital stay > 7 days 4%vs3.3%, patients presented above 97hrs 18.2%

as compared less than 48hr 2%, gangrenous SBV 8%vs.2.4% ,emergency procedure 6% vs0% conservative and Derotation and Milking 7%vs.4% in primary resection and analysis

Discussion

Small bowel volvulus is a rare cause of small bowel obstruction in the western and the USA [1, 2, 8]. The incidence rate of SBV is high (24-60per 100,000populations) in Africa, Asia and Middle Eastern while low (1.7–5.7 per 100,000populations) in western [6]. Annual occurrence in the USA and Europe is quite low compared with that in Africa, Middle East countries, and Asian [2–3, 7, 13–15] (Table 1). A 57 years data review in the USA found that annual occurrences of SBV was 0.6case per year and SBV accounted for 6.9% of all bowel obstruction [7]. Welch CE 1958 reported that the prevalence reduction from 6.9–3.3% in the period of 1930–1958 in the USA [16] .A. Roggo and L. W. Ottinger (1992) at the Massachusetts General Hospital over 10 years reported those 35 small bowel volvulus were treated which represented 1.7% of bowel obstructions and 4% of small bowel obstructions [7]. Vaez-Zadeh et al (1969) reported the incidence of small bowel volvulus in Iran was 19.6% and 41% in bowel obstruction and small bowel obstruction respectively [2]. A series of research done in Ethiopia t reported that the prevalence of small bowel volvulus was Tegegne A. 1992(18.3%) [9], Lintjorn B.1981et al (38.6%) [10], M. Demissie 2001(41.7%) [2], Gizaw TA.et al 2016, (36.4%) [11], Soressa U.et al 2016, (30.3%) [12] in all bowel obstruction. I.O.McDonald et al. 1980 reported more than 50% of bowel obstruction due to Small bowel volvulus in Nepal [5]. This great discrepancy of the prevalence of small bowel volvulus may due to dietary factors that when a bulky bolus of food entered the proximal jejunum, that loop felt down into pelvis and causing empty distal bowel to rise into a right upper quadrant. Rapid emptying of the stomach and diaphragm makes the distal bowel spread across the left upper quadrant. As this distal loop themselves filed up would fall into left quadrat completing 360⁰ twists [3]. Primary SBV is more common in developing countries while secondary SBV is more in developed countries. Frazee RC et.al 1988 (UK) and A.Roggo and L. W. Ottinger 1992(USA) noted that secondary SBV accounted for 89%&86% of SBV respectively [13, 7](Table 1). A Research done by Vaez-Zadeh et al 1969(Iran), M.Demssie 2001(Ethiopia) and De Souza LJ1976 (Uganda) showed that primary SBV accounted 80%, 94.9% and 100% of SBV respectively [2, 3, 15] (Table 1).We found that primary SBV accounted 100% of SBV. The presumed risk factors in different literature were hypermobility of bowel gut, hypermobility of mesentery, and bulky and poorly digestible diet taken at long intervals [2, 7, 13, 17].

The speculation was some populations have long mesenteric and short roots of mesentery which would allow abnormal mobility of whole or segment of the small bowel. Diet and pattern of feeding is also the most relevant risk factor for occurrences of primary SBV. The Abrupt change of dietary habit of ingestion of a single large amount and bulky food after a long interval of fasting or empty of bowel may induce forceful bowel peristalsis, resulting in SBV [2, 7, 13, 17]. Secondary small bowel volvulus occurs in the presence of underlying identified predisposed conditions. It is mainly seen in bands, post-op adhesion, malrotation, or midgut nonrotation in newborn and young children and a gastrointestinal infestation of

the parasite. The prevalence of secondary SBV is more common in western, constituting a 70–90% of case [7].

The prevalence of primary SBV is more common in children and young while secondary SBV is dominantly in old age. A study conducted in the different areas stated that the mean age was 67 years in the USA, 34 years in Ethiopia, 42 years in Iran, 59 in the UK [2,3,7,13] (Table 1). We found that the mean age was 42 years. The incidence of SBV is a male predominance, particularly in developing countries. The research described that male to female proportion 1:1.2 in USA, 1:1.12 in UK, 9.25:1 in Iran, 8.8:1 in Ethiopia [2, 3, 7, 13]. We found similar results on the male to female proportion 5.4:1 (Table 1). The exact cause of sex discrepancy is not well-illustrated but possible reasons suggested that spacious female pelvic area allowed a greater possibility of spontaneous reduction of volvulus, females have a lax abdominal wall due to childbearing, doing less heavy and prolonged exercise and more obese [2, 3, 7].

The literature review summarized the common complaints of SBV abdominal pain 94–100%, vomiting 83–100%, and abdominal distention 55–100% [7]. Our result identified the common clinical complaints of SBV similar to the previous review; abdominal pain 98%, vomiting 92.1% and distention 61.5% and frequent physical findings were abdominal tenderness 85.1% and visible peristalsis 64.9%.

SBV has been contributing a significant burden in mortality and morbidity especially when the bowel becomes gangrenous, ischemic, and develops peritonitis. The prevalence of gangrenous SBV depends on the health-seeking behavior of the community, access to a health facility, early diagnosis, and economy of the patients. The incidence of gangrenous SBV was 28.7 in Ethiopia, 46% in the USA, and 43% in the UK [2, 7, 13].

Our study found that the incidence of gangrenous SBV 16.9%. This difference study conducted in the USA and UK was in the early 1950s and currently increases access to surgical investigation modality decreasing the incidence of gangrenous SBV.

SBV had a high mortality rate but currently mortality due to SBV decreasing due to the advance of surgical health, investigation, and early diagnosis. Overall mortality rate reported 26% in Nepal, 13.3% in Ethiopia, 28% in UK, 9% in USA and 15% in Iran [2, 3, 5, 7, 13]. Our finding was lowered compared with the previous study (3.4%).

Conclusion:

Annual occurrence of SBV was 37 cases per year. The prevalence of SBV was 59% of small bowel obstruction and 36.3% of bowel obstruction respectively. It had low morbidity and mortality rate (5.4 & 3.4% respectively). The majority of SBV were respond with conservative treatment with NPO, NGT decompression and Resuscitation (43.2%).
