Abstract

Background

Aberrant expression of exosomal miRNAs has emerged as a research hotspot in cancer studies. However, no studies have been conducted on the dysregulation of exosomal miRNAs derived from cancer-associated fibroblasts (CAFs) in supraglottic laryngeal squamous cell carcinoma (SLSCC).

Methods

CAFs and paired normal fibroblasts (NFs) from SLSCC patients were cultured, and exosomes in the culture supernatants were collected and identified by transmission electron microscopy, nanoparticle tracking analysis and western blotting. Exosomal miRNA expression was compared in each pair of CAFs and NFs by next-generation sequencing. Four online bioinformatic algorithms predicted the potential target genes of aberrantly expressed miRNAs, while gene ontology and Kyoto Encyclopaedia of Genes and Genomes (KEGG) pathway enrichment and network analysis identified downstream target genes and their interactions.

Results

Three pairs of CAFs and NFs were successfully cultured and purified. CAF-derived exosomal miRNAs were mostly downregulated and included miR-656-3p, miR-337-5p, miR-29a-3p and miR-655-3p; however, some, including miR-184-3p, miR-92a-1-5p, miR-212-3p and miR-3135b, were upregulated. Bioinformatics analysis revealed involvement of these miRNAs in biological processes, cellular components and molecular functions. KEGG analysis revealed the top thirty pathways involvement in cancer initiation and progression and in cell cycle regulation. An interaction network showed miR-16-5p, miR-29a-3p, miR-34c-5p, miR-32-5p and miR-490-5p as the top five miRNAs and CCND1, CDKN1B, CDK6, PTEN and FOS as the top five target genes.

Conclusions

SLSCC patients showed aberrant expression of CAF-derived exosomal miRNAs. The target genes may jointly constitute a carcinogenic tumour microenvironment and may play decisive roles in the initiation and progression of SLSCC.

Background

Supraglottic laryngeal squamous cell carcinoma (SLSCC) is a special type of laryngeal cancer that is prone to lymph node metastasis and post-therapeutic relapse [1]. Tumour relapse is mainly caused by a disordered tumour microenvironment (TME) [2, 3], caused in part by the pro-tumourigenic capacity of

cancer-associated fibroblasts (CAFs), one of the most abundant stromal cell types in the TME [4, 5]. CAFs produce extensive exosomes—extracellular vesicles with diameters ranging from 30 to 100 nm—that regulate the TME and direct the growth and progression of cancer cells [6, 7].

Exosomes carry a variety of bioactive molecules, including miRNAs, signal peptides, lipids and DNA [8]. Of these molecules, the exosomal miRNAs play an important role in the modulation of the TME, and the aberrant expression of the exosome-derived miRNAs in CAFs are recognized as important contributors to cancer progression, metastasis and therapeutic resistance in different solid tumours [9]. The pro-tumourigenic potential of CAF-derived exosomal miRNAs has been validated by several recent studies [6, 10–12]. However, to date, no studies have been conducted to explore the aberrant expression profiles of CAF-derived exosomal miRNAs in patients with SLSCC.

In the present study, we compared exosomal miRNAs from pairs of CAFs and normal fibroblasts (NFs) to identify the aberrant expression profiles of CAF-derived exosomal miRNAs obtained from different patients with SLSCC. We then characterized the associated target genes and used bioinformatics analysis to identify vital signalling pathways. A few similar studies have been reported previously, but those studies focused on only a single pair of CAFs and NFs. For more reliable data, we collected ten pairs of SLSCC and normal connective tissue specimens for culture. However, only three pairs were successfully cultured and purified due to contamination or poor propagation capacity of NFs in vitro. The aberrant expression profiles of exosomal miRNAs from the three pairs of CAFs and NFs were identified using next-generation sequencing.

Most of the dysregulated exosomal miRNAs were downregulated, including miR-656-3p, miR-337-5p, miR-29a-3p, miR-655-3p, miR-16-5p, miR-34c-5p, miR-32-5p and miR-490-5p. A few dysregulated exosomal miRNAs were upregulated, including miR-184-3p, miR-92a-1-5p, miR-212-3p, miR-3135b, miR-1306-3p, miR-7704 and miR-1306-3p. The potential downstream target genes and their interactions with these selected exosomal miRNAs were explored by online bioinformatics analysis. Taken together, our findings indicate that these aberrantly expressed exosomal miRNAs, their target genes and the related vital signalling pathways may play critical roles in SLSCC initiation and progression and may provide new insights for the treatment of SLSCC.

Methods

Patient information

Ten tumour specimens from ten male patients with SLSCC diagnosed by biopsy and pathology were collected immediately after surgical tumour resection. All ten specimens were classified as moderately differentiated epiglottic LSCC. Paired adjacent normal connective tissues were obtained simultaneously from each patient. Data including laryngoscopic photos, contrast-enhanced computed tomography (CT) scans and pathologic photos were also collected.

Primary culture of tumour specimens and paired adjacent connective tissues

Each SLSCC specimen collected from fresh resected tumours was immersed immediately in cold RPMI 1640 medium (Invitrogen, Grand Island, NY, USA). The specimen was then immersed in povidone-iodine solution (saline-diluted, 1:10, 5 min), followed by gentamycin sulphate solution (saline-diluted, 1:8, 5 min) and finally lincomycin hydrochloride solution (saline-diluted, 1:8, 5 min). The specimen was then washed with phosphate-buffered saline (PBS) and scissored into fragments (1–2 mm³). The fragments were trypsinised in RPMI 1640 medium containing type IV collagenase (200 U/mL, Sigma, St. Louis, MO, USA) for 12 h at 37 °C. The digested fragments were suspended in bronchial epithelial cell growth medium (BEGM; Catalogue #CC-3170; Lonza, Walkersville, MD, USA) supplemented with 1% penicillin/streptomycin and 10% foetal bovine serum (FBS; Gibco, Life Technologies Corporation, Grand Island, NY, USA). The suspension was plated in 6 cm Petri dishes (Corning Inc., Corning, NY, USA) and incubated for 3–7 days in a humidified incubator in 5% CO₂ at 37°C. The dishes were then examined under a phase-contrast microscope and any contaminated dishes were discarded. The CAFs that grew successfully without contamination were collected and subcultured.

The paired adjacent connective tissue from the same patient was cultured using this same procedure and served as a control. Primary CAF and NF cultures were successfully generated from tissues from three of the ten patients.

Morphological examination and immunocytochemical staining of CAFs and NFs

CAFs and NFs were separated and purified by brief exposure to 0.25% trypsin-EDTA (Invitrogen, Grand Island, NY, USA). Representative images were recorded using a phase-contrast microscope. Immunocytochemistry was used to verify the identities of CAFs and NFs. The CAFs and NFs cells suspended in BEGM were plated on glass coverslips. The cells were then incubated at 37 °C for 24 h and immersed in 4% paraformaldehyde (PFA) for 15 min, washed with PBS, and incubated in 10% normal goat serum (Boster, Wuhan, China) for 40 min to block nonspecific interactions, in the presence or absence of 0.3% Triton X-100 to permeabilise the cells. The coverslips were immersed in solutions containing primary antibodies (rabbit antihuman) for pan-cytokeratin (CK; 1:400; Abcam, Cambridge, UK), vimentin (1:200; Abcam), α-smooth muscle actin (α-SMA; 1:200; Abcam) and fibroblast activation protein (FAP; 1:250; Abcam) and incubated at 4 °C overnight. The cells were then treated with secondary antibodies (Jackson ImmunoResearch, West Grove, PA, USA), either fluorescein isothiocyanate (FITC)-conjugated goat anti-rabbit IgG (H + L; 1:100) or CyTM3-conjugated goat anti-rabbit IgG (1:100) for 1 h at 37 °C. The cell nuclei were stained with 4',6-diamidino-2-phenylindole (DAPI; Boster).

Collection of culture supernatant and isolation of exosomes

Purified CAFs and NFs were cultured in BEGM medium (containing 10% exosome-depleted FBS) for 72 h. When each cell monolayer was near confluence, the culture supernatant was collected and centrifuged (1500 g, 10 min), followed by centrifugation (10,000 g, 30 min) at 4°C. The resulting exosome supernatant was then filtered (0.22 µm filter) to eliminate cellular debris, followed by centrifugal ultrafiltration (Amicon® Ultra-15 100 KDa; Merck KGaA) to prevent potential contamination. Exosomes were isolated from the ultrafiltered supernatant with Ribo™ Exosome Isolation Reagent (RiboBio Co., Ltd., Guangzhou, China), as previously described [13]. Briefly, the collected conditioned medium was mixed with Ribo™ Exosome Isolation Reagent (ratio 3:1), followed by an incubation at 4°C overnight. The medium was then centrifuged (1500 g, 30 min) and the resulting exosome pellets were suspended in phosphate-buffered saline (PBS; HyClone; GE Healthcare Life Sciences) and analysed immediately or stored at -80°C for subsequent research.

Transmission electron microscopy (TEM) and nanoparticle tracking analysis (NTA)

TEM was used to identify the morphological characteristics of exosome pellets, as described previously [13]. About 20 µL of exosome-PBS solution was added to carbon-coated copper grids for 1 min and then the excess solution was removed by blotting with filter paper. The exosome pellets were then stained with 20 µL uranyl acetate dihydrate (2%) for about 1 min. The sample was finally dried for 10 min under a lamp before observation with an FEI Tecnai G2 Spirit transmission electron microscope (FEI Company, Hillsboro, OR, USA) operated at 80 kV. The particle size distribution was determined by NTA using a NanoSight NS300 instrument (Malvern Instruments, Inc., Westborough, MA, USA), in accordance with the operating instructions.

Western blotting

Cell pellets and exosomes were lysed in RIPA lysis buffer. The protein concentration was determined, and protein samples from exosomes and control cells were separated by SDS polyacrylamide gel electrophoresis, followed by transfer to PVDF membranes (Millipore, Billerica, MA, USA). The membranes were initially blocked with 5% nonfat milk and probed overnight with rabbit primary anti-CD63 (1:1000, Abcam), anti-TSG101 (1:2000, Abcam) and anti-Calnexin (1:2000, Invitrogen), followed by detection using horseradish peroxidase-conjugated goat anti-mouse/rabbit/rat IgG (1:2,000; Jackson, Lancaster, PA, USA). Immunoreactive bands were detected using BeyoECL Plus (Beyotime Biotech, Nantong, China). Beta-actin antibody (1:5,000; HuaAn Biotech, Hangzhou, China) was used to normalise the amount of sample loaded.

Extraction of total RNA

TRIzol reagent (Invitrogen; Thermo Fisher Scientific, Inc., Waltham, MA, USA) was used to extract high-quality total RNA from the exosomes obtained from each specimen. A NanoDrop 2000 spectrophotometer (NanoDrop Technologies; Thermo Fisher Scientific, Inc.) was used to analyse the concentration and quality of RNA. An Agilent 2200 Bioanalyser (Agilent Technologies, Inc., Santa Clara, CA, USA) was used to assess the RNA content.

Small RNA (sRNA) sequencing

The sRNA next-generation sequencing technology was used to investigate differences in the miRNA profiles between exosomes from the three pairs of CAFs and NFs. The sRNA library preparation and sample sequencing were performed with the assistance of RiboBio Co., Ltd. (Guangzhou, China) using an Illumina HiSeq™ 2500 device, as described previously [13]. Briefly, total RNA from the three pairs of CAF and NF exosomes were concatenated with 5'- and 3'-adaptors, followed by cDNA synthesis and PCR amplification. The cDNA library (18–40 nt) was then obtained by acrylamide gel purification and single end (SE) sequencing was conducted (1×50 bp).

Identification of candidate exosomal miRNAs and target genes

The miRNAs that showed significant differences ($P < 0.05$) between CAFs and NFs were selected as candidate exosomal miRNAs for further analysis. The genes targeted by selective exosomal miRNAs were predicted by four online bioinformatic algorithms: TargetScan (http://www.targetscan.org/vert_72/), miRDB (<http://mirdb.org>), miRTarBase (<http://mirtarbase.mbc.nctu.edu.tw/php/index.php>) and miRWalk (<http://mirwalk.umm.uni-heidelberg.de>). We selected an intersection among the four databases as a filtering condition to improve the accuracy of gene prediction. Only genes predicted simultaneously by specific exosomal miRNAs within the four databases were selected as target genes of the candidate exosomal miRNAs.

Gene Ontology (GO) and Kyoto Encyclopaedia of Genes and Genomes (KEGG) analysis

The GO analysis (<http://www.geneontology.org/>) was used to predict the potential functions of the target genes of selected miRNAs, while the KEGG (<http://www.genome.jp/>) pathway enrichment analysis was performed to identify the predominant pathways based on the DAVID 6.7 online software (<http://david.abcc.ncifcrf.gov/home.jsp>). All GO terms and KEGG pathway enrichment analysis were analysed with a $P < 0.05$ threshold of significance.

Results

Laryngoscopy, contrast-enhanced CT and pathology

Laryngoscopy revealed that all the three SLSCC tumours originated from the epiglottis and showed obvious enhancement in CT scans. Pathological examination showed that all tumours were moderately differentiated squamous cell carcinomas (Fig. 1a-i).

Primary culture, purification and morphology of CAFs and NFs

Although ten pairs of CAFs and NFs from ten SLSCC patients were initially subjected to primary culture, only three pairs were successfully cultured and purified due to contamination or poor propagation of the NFs in vitro. Two days after seeding, the CAFs, cancer cells and NFs grew out from the fragments. The CAFs and NFs were purified by differential trypsinisation at passages 3–4. Purified CAFs and NFs were stored in liquid nitrogen. The morphology of the NFs showed small differences when compared with the CAFs. For example, fewer cell prominences were formed by the NFs than by the CAFs (Fig. 2a-h). During subculture, the proliferation capacity of CAFs and NFs did not decrease significantly within 7 consecutive passages. Therefore, CAFs and NFs between passages 3 and 6 were used for subsequent assays.

Purity and identification of CAFs and NFs by immunofluorescence

Negative staining for pan-CK and positive staining for vimentin were detected in CAFs and NFs, confirming their fibroblast origin. The purity of CAFs and NFs revealed by vimentin staining was 100%, as validated by examining 10 randomly selected microscopic fields ($\times 200$). In comparison with the NFs, CAFs also showed positive staining for FAP and α -SMA, two CAF biomarkers (Fig. 2i-r).

Isolation and identification of exosomes derived from CAFs and NFs

Exosomes were verified by TEM, western blotting and NTA. TEM images showed the typical size range and morphology of membrane-bound exosome particles, which were homogeneous in appearance (Fig. 2s). Western blotting revealed positive expression of CD63 and TSG101, two of the well-established surface markers for exosomes, and negative expression of calnexin, commonly used as a negative control for extracellular vesicles [14, 15] (Fig. 2t). In addition, NTA analysis showed a size distribution (mean diameter at $109.1 \pm 44.1\text{nm}$) for the exosome particles that was consistent with the reported size range of exosomes (30–150 nm) [16] (Fig. 2u).

Different small RNA signatures of the exosome compartments derived from CAFs and NFs

High-throughput sequencing was performed using RNA samples extracted from exosomes derived from the three pairs of CAFs and NFs. Most of the exosomal clean reads could be mapped to known RNAs of the human genome, as illustrated in the circos plots (Fig. 3). Analysis of the chromosomal location of all the mapped small RNAs indicated that they mainly originated from chromosomes 3, 5, 6, 7, 13 and 14. No significant differences were noted between CAFs and NFs for the distribution of the exosomal small RNA location in the genome (Fig. 3a). Approximately 12.3% of the miRNAs were common between CAFs-derived and NFs-derived exosomes (Fig. 3b). The small RNA reads were functionally categorised based on a >90% identity to exonic regions of the genome and annotated ncRNAs. Briefly, the miRNAs were the most abundant among the known sequences, followed by tRNAs, rRNA, snRNAs, snoRNA, Y RNAs, piRNAs and other RNAs that could not be categorised. Of all the small RNAs sequenced, an average of 67.61% of the miRNAs were detected in CAF-derived exosomes, compared with an average of 62.50% of the miRNAs in NF-derived exosomes (Fig. 3c). Small RNAs, sized between 17 nt and 45 nt, were analysed. Most of the sequenced small RNAs were approximately 20 nt and 31 nt in size (clean reads). These characteristic sizes were consistent with small RNA populations (Fig. 3d).

Aberrant expression profiles of exosomal miRNAs between CAFs and NFs

The sRNA next-generation sequencing technology was used in this assay. Total RNA was extracted from three pairs of CAF and NF exosomes. A small RNA library was prepared and samples were sequenced. Patient YYX had 668 dysregulated miRNAs; however, only 45 miRNAs showed significant differences in expression. Of those, 3 (hsa-miR-184, hsa-miR-92a-1-5p and hsa-miR-212-3p) were upregulated and 42 were downregulated ($P<0.05$, Table 1). Patient XHG had 576 dysregulated miRNAs, but only 45 miRNAs showed significant differences in expression. Of those, 9 (hsa-miR-184, hsa-miR-3135b, hsa-miR-7704, hsa-miR-485-3p, hsa-miR-365a-5p, hsa-miR-1248, hsa-miR-342-5p, hsa-miR-370-5p and hsa-miR-550a-3-5p) were upregulated and 36 were downregulated ($P<0.05$, Table 2). Patient YSX had 476 dysregulated miRNAs, but only 33 miRNAs showed significant differences in expression. Of those, 8 (hsa-miR-92a-1-5p, hsa-miR-1306-3p, hsa-miR-205-5p, hsa-miR-200b-5p, hsa-miR-615-3p, hsa-miR-4448, hsa-miR-223-5p and hsa-miR-412-5p) were upregulated and 25 were downregulated ($P<0.05$, Table 3) (Fig. 4). Eleven miRNAs (miR-452-5p, miR-651-5p, miR-16-5p, miR-424-5p, miR-378d, miR-32-5p, let-7i-3p, miR-16-2-3p, miR-136-3p, miR-221-5p, miR-34c-5p) were downregulated simultaneously in two patients. Two miRNAs (miR-184, miR-92a-1-5p) were upregulated simultaneously in two patients. Four miRNAs (miR-656-3p, miR-655-3p, miR-337-5p, miR-29a-3p) were downregulated simultaneously in all the three patients (Fig. 5a, pie chart).

Prediction of miRNAs target genes and GO and KEGG pathway enrichment analysis

The target gene prediction analysis of differentially expressed miRNAs between CAF-derived and NF-derived exosomes was performed using the TargetScan, miRDB, miRWALK and miRTarBase online

databases. Only the genes predicted simultaneously by all four servers were considered target genes of a specific miRNA.

The GO approach used to explore potential gene functions revealed that all the GO terms were involved in three categories: biological process, cellular component and molecular function. The top three biological processes (the lowest P-value, $P<0.05$) were related to regulation of transcription from the RNA polymerase II promoter, transcription from the RNA polymerase II promoter and positive regulation of RNA metabolic processes. The top three cellular components (the lowest P-value, $P<0.05$) were related to the RISC-loading complex, the micro-ribonucleoprotein complex and the RNAi effector complex. The top three molecular functions (the lowest P-value, $P<0.05$) were related to core promoter binding, regulatory region nucleic acid binding transcription factor activity and transcription regulatory region DNA binding (Fig. 5b-d, Fig.6a).

The KEGG pathway enrichment analysis was performed to characterise the predominant pathways. The specific miRNA targets were compared to the whole reference gene background, and $P<0.05$ was chosen as the cut-off criterion. Thirty signalling pathways with the most statistical differences were selected and analysed (Fig. 6b). These 30 pathways were involved in many types of cancers (non-small cell lung cancer, endometrial cancer, renal cell carcinoma, chronic myeloid leukemia, melanoma, colorectal cancer, pancreatic cancer, glioma, small cell lung cancer), several signalling pathways critical for cancer (the MAPK, mTOR, ErbB, Ras, p53, PI3K-Akt and FoxO signalling pathways), the cell cycle, miRNAs in cancer, signalling pathways regulating the pluripotency of stem cells and other cancer-related molecular functions (focal adhesion, adherens junctions and EGFR tyrosine kinase inhibitor resistance).

Interaction networks of exosomal miRNAs and target genes

One miRNA can regulate hundreds of target genes, and one gene can be regulated by multiple miRNAs. An interaction network of selected exosomal miRNAs and genes were constructed. In all, 12 aberrantly expressed exosomal miRNAs were identified that formed a wide range of connections with the corresponding target genes. The top five were miR-16-5p, miR-29a-3p, miR-34c-5p, miR-32-5p and miR-490-5p (Fig. 7a). The top five most common overlay genes were identified as CCND1 (gene count 10), CDKN1B (gene count 7), CDK6 (gene count 6), PTEN (gene count 5) and FOS (gene count 5) (Fig. 7b, Table 4).

Discussion

Increasing evidence reveals that dysregulation of exosomal miRNAs in the TME plays a critical role in cancer initiation, proliferation, vascularisation and metastasis, as well as other biological characteristics [17, 18]. Exosomal miRNAs may be derived from cancer cells themselves or from stromal cells like CAFs. To date, most studies have focused on exosomal miRNAs derived from cancer cells [19, 20]. CAF-derived

exosomal miRNAs are now receiving increasing attention, but no studies have yet been conducted to explore the aberrant expression profiles of exosomal miRNAs derived from CAFs in patients with SLSCC.

The present study is the first to describe dysregulation of the expression profile of miRNAs encapsulated in the CAF-derived exosomes in different patients with SLSCC and analysis of the potential involvement of their signalling cascade in cancer progression. Previous investigations have focused on only a single pair of CAFs and NFs, whereas we initially collected ten pairs of SLSCC specimens and paired normal connective tissues for primary culture. Three pairs were successfully cultured and used for subsequent investigations. Laryngoscopy revealed that all three SLSCC tumours originated from the epiglottis, with obvious enhancement in CT scans. Pathological examination showed that they were all moderately differentiated squamous cell carcinomas (Fig. 1a-i).

Both the CAFs and NFs showed long, fusiform morphology, with several cell prominences. However, the cell prominences were fewer on the NFs than on the CAFs, which probably reflected the fact that they were in a relatively inactive state (Fig. 2a-h). After purification, the CAFs were distinguished from the NFs by positive immunofluorescence staining for FAP and α-SMA, two CAFs biomarkers, indicating their activated state (Fig. 2i-r).

Exosomes, as intraluminal vesicles, range in size from 30 to 150 nm and can be isolated by various methods, such as ultracentrifugation, chromatography, density gradient separation and immunoaffinity capture techniques [21, 22]. In the present study, exosomes were isolated from conditioned media surrounding the CAFs and NFs using Ribo™ Exosome Isolation Reagent, as previously described [13].

The collected exosomes were verified as such by TEM, western blotting and NTA. TEM showed the typical size and morphology of membrane-bound exosome particles (Fig. 2s). Previous studies have reported that exosomes are generally enriched with certain specific marker proteins, such as CD9, CD63, CD81, TSG101 and HSP70 [23, 24], with lower expression of some cellular proteins, such as cis-Golgi matrix protein GM130 [25] and endoplasmic reticulum (ER) calnexin [14, 15]. Exosomes can therefore be identified by western blotting or flow cytometry. In the present study, we selected CD63 and TSG101 (two of the well-established surface markers for exosomes) and calnexin (a negative marker of extracellular vesicles) to confirm the isolation of exosomes by western blotting. The blots revealed the presence of CD63 and TSG101 and the absence of calnexin, consistent with the previously reported characteristics of exosomes markers (Fig. 2t). In addition, NTA analysis showed the exosome particles to have a size of 109 ± 44.1 nm, which was consistent with the reported size range of exosomes (30–150 nm) [26] (Fig. 2u). Our findings confirmed that these isolated particles qualified as exosomes.

We also analysed the chromosomal locations and sequence lengths of the target small RNAs extracted from the exosomes derived from all three pairs of CAFs and NFs. We found that all the mapped small RNAs mainly originated from chromosomes 3, 5, 6, 7, 13 and 14. No significant difference was detected for the distribution of exosomal small RNAs locations in the genome between CAFs and NFs (Fig. 3a). Most sequenced small RNAs had a size of approximately 20 nt and 31 nt (clean reads), which was consistent with small RNA populations (Fig. 3d).

The aberrant expression profiles of exosomal miRNAs derived from the three pairs of purified CAFs and NFs from patients with SLSCC were then analysed by next-generation sequencing (Table 1–3, Fig. 4). Most of the aberrantly expressed miRNAs were downregulated, but a few were upregulated. Eleven miRNAs (miR-452-5p, miR-651-5p, miR-16-5p, miR-424-5p, miR-378d, miR-32-5p, let-7i-3p, miR-16-2-3p, miR-136-3p, miR-221-5p and miR-34c-5p) were downregulated simultaneously in two patients. Two miRNAs (miR-184 and miR-92a-1-5p) were upregulated simultaneously in two patients. Interestingly, four exosomal miRNAs (miR-656-3p, miR-655-3p, miR-337-5p and miR-29a-3p) were downregulated simultaneously in the purified CAFs from all three patients (Fig. 5a, pie chart).

A few reports have appeared about miR-656-3p and miR-337-5p and a few about miR-655-3p in different types of cancers. For example, miR-656-3p was found to be dysregulated in colon cancer tissues [27] and downregulated in non-small cell lung cancer tissues [28]. Overexpression of miR-337-5p in colorectal cancer tissues was significantly associated with improved overall survival [29]. Downregulation of miR-655-3p was reported in ovarian cancer tissues [30] and in hepatocellular carcinoma tissues and cell lines [31]. However, all three miRNAs in these reports were extracted either from tumour tissues or from cancer cell lines. None of the miRNAs were extracted from exosomes, let alone from the CAF-derived exosomes from different patients with SLSCC.

MiR-29a-3p is a potential tumour-suppressive miRNA and is downregulated in several cancer tissues, such as papillary thyroid carcinoma tissues and cell lines [32], hepatocellular carcinoma tissues and cell lines [33], gastric cancer tissues [34] and high-grade glioma tissues [35]. More studies have been conducted on miR-29a-3p than on miR-656-3p, miR-337-5p or miR-655-3p, and studies on exosome-derived miR-29a-3p are very rare. We found only one report that examined exosomal miR-29a-3p from oral squamous cell carcinoma cell lines [36]. No studies have reported CAF-derived exosomal miR-29a-3p.

Eleven miRNAs (miR-452-5p, miR-651-5p, miR-16-5p, miR-424-5p, miR-378d, miR-32-5p, let-7i-3p, miR-16-2-3p, miR-136-3p, miR-221-5p and miR-34c-5p) were downregulated simultaneously in two patients. However, the results in previous reports were controversial. The expression of miR-452-5p was significantly increased in 387 clinical lung squamous cell carcinoma specimens [37] and renal cell carcinoma tissues [38], whereas it was downregulated in 1007 prostate cancer samples [39]. MiR-16-5p has been proposed to function as a tumour suppressor and it was downregulated in non-small cell lung cancer cell lines [40], breast cancer samples [41], hepatocellular carcinoma tissues [42], chordoma tissues [43] and glioma tissues [44]. It was also downregulated in the plasma of gastric cancer patients [45]. However, exosomal miR-16-5p was upregulated in malignant mesothelioma cell lines [46]. The expression of miR-424-5p was significantly decreased in liver cancer tissues [47], intrahepatic cholangiocarcinoma tissues [48] and basal-like breast cancer tissues and cell lines [49]. However, it was upregulated in laryngeal squamous cell carcinoma tissues [50], thyroid cancer tissues [51], gastric cancer tissues and cells [52] and oesophageal squamous cell carcinoma tissues and cell lines [53]. A significant downregulation of miR-32-5p was reported in cervical cancer tissues and cells [54], but a significantly upregulation was detected in colorectal cancer tissues [55] and prostate cancer tissues and cells [56]. MiR-34c-5p was downregulated in leukaemia stem cells [57], osteosarcoma tissues and cells [58] and

aryngeal squamous cell carcinoma [59]. Let-7i-3p was upregulated in the serum-derived exosomes from osteosarcoma patients [60], but downregulated in the sera of lung cancer patients [61] and in hepatoblastoma tumours [62]. MiR-16-2-3p was downregulated in locally advanced gastric cancer samples [63] and upregulated in sera of patients with pancreatic ductal adenocarcinoma [64]. MiR-221-5p was significantly upregulated in renal cell carcinoma tissues and cell lines [65], but downregulated in prostate cancer samples [66]. No studies have reported the regulation of miR-651-5p, miR-378d and miR-136-3p in cancer research.

The two miRNAs (miR-184, miR-92a-1-5p) that were upregulated simultaneously in two patients in our study have also had controversial findings. For example, miR-184 expression was upregulated in tongue squamous cell carcinoma tissues and cell lines [67, 68], hepatocellular carcinoma tissues [69] and renal carcinoma tissues [70], but it was downregulated in glioblastoma tissues and cell lines [71], nasopharyngeal carcinoma cell lines [72] and endometrial carcinoma tissues [73]. MiR-92a-1-5p was upregulated in tumours from the luminal A to the basal-like prostate cancer subtypes [74] but downregulated in urinary exosomes from prostate cancer patients [75]. These results suggest that these miRNAs play different regulatory roles in different types of tumours.

However, most of the miRNAs reported in different studies were extracted from either tumour tissues or cancer cell lines. Most of the exosomal miRNAs reported in different studies were conducted using miRNAs extracted from cancer cell-derived exosomes. Although increasing studies focused on the exosomal miRNAs extracted from CAFs, almost all of them used only one pair of CAFs and NFs. And almost no of them were conducted using miRNAs extracted from exosomes derived from CAF primary cultures from different patients. We believe that the miRNAs with the most significant statistical difference or showing the same expression trends in more than one patient sample are the miRNAs that jointly constitute a carcinogenic TME and play decisive roles in the initiation and progression of SLSCC.

The bioinformatics analysis using four online databases (TargetScan, miRDB, miRWalk and miRTarBase) predicted the potential target genes of the exosome miRNAs that were differentially expressed between CAFs and NFs. Our exploration of the potential functions of these target genes using GO analysis revealed an involvement of three GO categories (biological process, cellular component and molecular function) that had transcription and regulation of RNA as important functions (Fig. 5b-d, Fig. 6a). The KEGG pathway enrichment analysis identified the top thirty pathways involved in many types of cancers, in critical signalling pathways in cancer initiation and progression and in regulation of the cell cycle. Our findings indicated that the differentially expressed exosomal miRNAs play a critical role in the processes of tumourigenesis and in the regulation of cancer-associated signalling pathways, the cell cycle and other aspects of cancer biology (Fig. 6b).

We also constructed an interaction network of selected exosomal miRNAs and target genes. This network contained 12 aberrantly expressed exosomal miRNAs that formed a wide range of connections with the corresponding target genes (Fig. 7a). Of these, the top five miRNAs were miR-16-5p, miR-29a-3p, miR-34c-5p, miR-32-5p and miR-490-5p. MiR-16-5p was reportedly downregulated in breast cancer [76],

hepatocellular carcinoma [77] and glioma [78], in agreement with our findings. Overall, miR-29a-3p has been reported to function as a tumour suppressor and is downregulated in many types of cancers, such as thyroid carcinoma [32], colorectal carcinoma [79] and hepatocellular carcinoma [80]. The downregulation of miR-34c-5p has been reported in several types of cancer, such as leukaemia [57] and osteosarcoma [58], and it has been closely associated with poor prognosis. Similarly, miR-490-5p is markedly downregulated in hepatocellular carcinoma tissues [81], in renal cell carcinoma tissues and cells [82] and in childhood neuroblastomas and cell lines [83]. MiR-32-5p was significantly downregulated in cervical cancer tissues and cells [54] but significantly upregulated in colorectal cancer tissues [55]. In our study, the expression of exosomal miR-32-5p was significantly repressed in CAFs compared to NFs, indicating that miR-32-5p might play different regulatory roles in different cancers.

We also found the top five most common overlay target genes (CCND1, CDKN1B, CDK6, PTEN and FOS) (Fig. 7b, Table 4). Of these, CCND1, CDKN1B and CDK6 are critical regulatory subunits required for the cell cycle G1/S transition. Cancer cells frequently overcome pRb-dependent growth inhibition by phosphorylation thereby inactivating pRb function by cyclin-dependent kinase (CDK) partnered with cyclin D, termed cyclin-CDK complexes. The CDKN1B gene that encodes for the p27 protein, acts as a cyclin dependent kinase (CDK) inhibitor. Dysfunction of these three genes may therefore lead to uncontrolled cell cycle progression and ultimately to tumourigenesis [84, 85].

PTEN acts as an inactivated tumour suppressor gene in cancer. It is a critical negative regulator of the PI3K signalling pathway, which is one of the most significant cell growth and survival signalling pathways in cancer. Variation in or loss of the PTEN gene is commonly observed in many types of human cancers. PTEN inhibits tumourigenesis through different mechanisms, such as phosphatase-dependent and independent activities that modulate a variety of cellular functions including DNA repair, growth, proliferation and cell motility [86, 87]. The Fos gene family (c-Fos, FosB, Fra-1 and Fra-2) dimerise with Jun proteins to form the transcription factor complex AP-1. Genes regulated by AP-1 include important regulators of proliferation, differentiation, invasion, metastasis, hypoxia and angiogenesis [88] and may play important roles in the initiation and progression of cancer.

Conclusions

Primary cultures were successfully obtained for three pairs of CAFs and NFs from ten SLSCL patients. The aberrant expression profile of CAF-derived exosomal miRNAs was then identified by next-generation sequencing. Important functions of the predicted target genes were revealed by bioinformatics analysis. The top thirty pathways involved in cancer initiation and progression and in cell cycle regulation were identified by KEGG analysis. The top five miRNAs, miR-16-5p, miR-29a-3p, miR-34c-5p, miR-32-5p and miR-490-5p, and the top five most common overlay target genes, CCND1, CDKN1B, CDK6, PTEN and FOS, were revealed by the interaction network. Our findings predict that these critical miRNAs and target genes may jointly constitute a carcinogenic TME and may play decisive roles in the initiation and progression of SLSCL. Therefore, they may represent promising candidate targets for therapeutic intervention. However, these predictions require further experimental exploration in future studies.

Abbreviations

CAFs: cancer-associated fibroblasts; SLSCC: supraglottic laryngeal squamous cell carcinoma; NFs: normal fibroblasts; TEM: transmission electron microscopy; NTA: nanoparticle tracking analysis; GO: Gene Ontology; KEGG: Kyoto Encyclopaedia of Genes and Genomes; TME: tumour microenvironment; CT: computed tomography; PBS: phosphate-buffered saline; BEGM: bronchial epithelial cell growth medium.

Declarations

Acknowledgments

We thank Dr. Zuopeng Lin in RiboBio Co., Ltd (Guangzhou, China) for his great help in bioinformatics analysis.

Author's contributions

Chunping Wu, Mei Wang and Liang Zhou conceived and designed the study. Chunping Wu, Qiang Huang and Chunyan Hu performed the experiments. Chunping Wu, Mei Wang, Yang Guo and Hongli Gong analysed the data. Chunping Wu and Mei Wang wrote the manuscript. Yang Guo, Hongli Gong and Liang Zhou reviewed and edited the manuscript. All authors read and approved the final manuscript.

Funding

This study was supported by grants from the National Natural Science Foundations of China (grant no. 81972529)

Availability of data and materials

All data generated or analysed during this study are available in this published article.

Ethics approval and consent to participate

All SLSCC specimens were obtained with the approval of the Ethics Committee of the Eye, Ear, Nose and Throat Hospital, Fudan University, Shanghai, China. Signed informed consents were obtained from all patients included in this study.

Consent for publication

All authors reached an agreement to publish the study in this journal.

Competing interests

The authors declare that they have no competing interests.

Figures

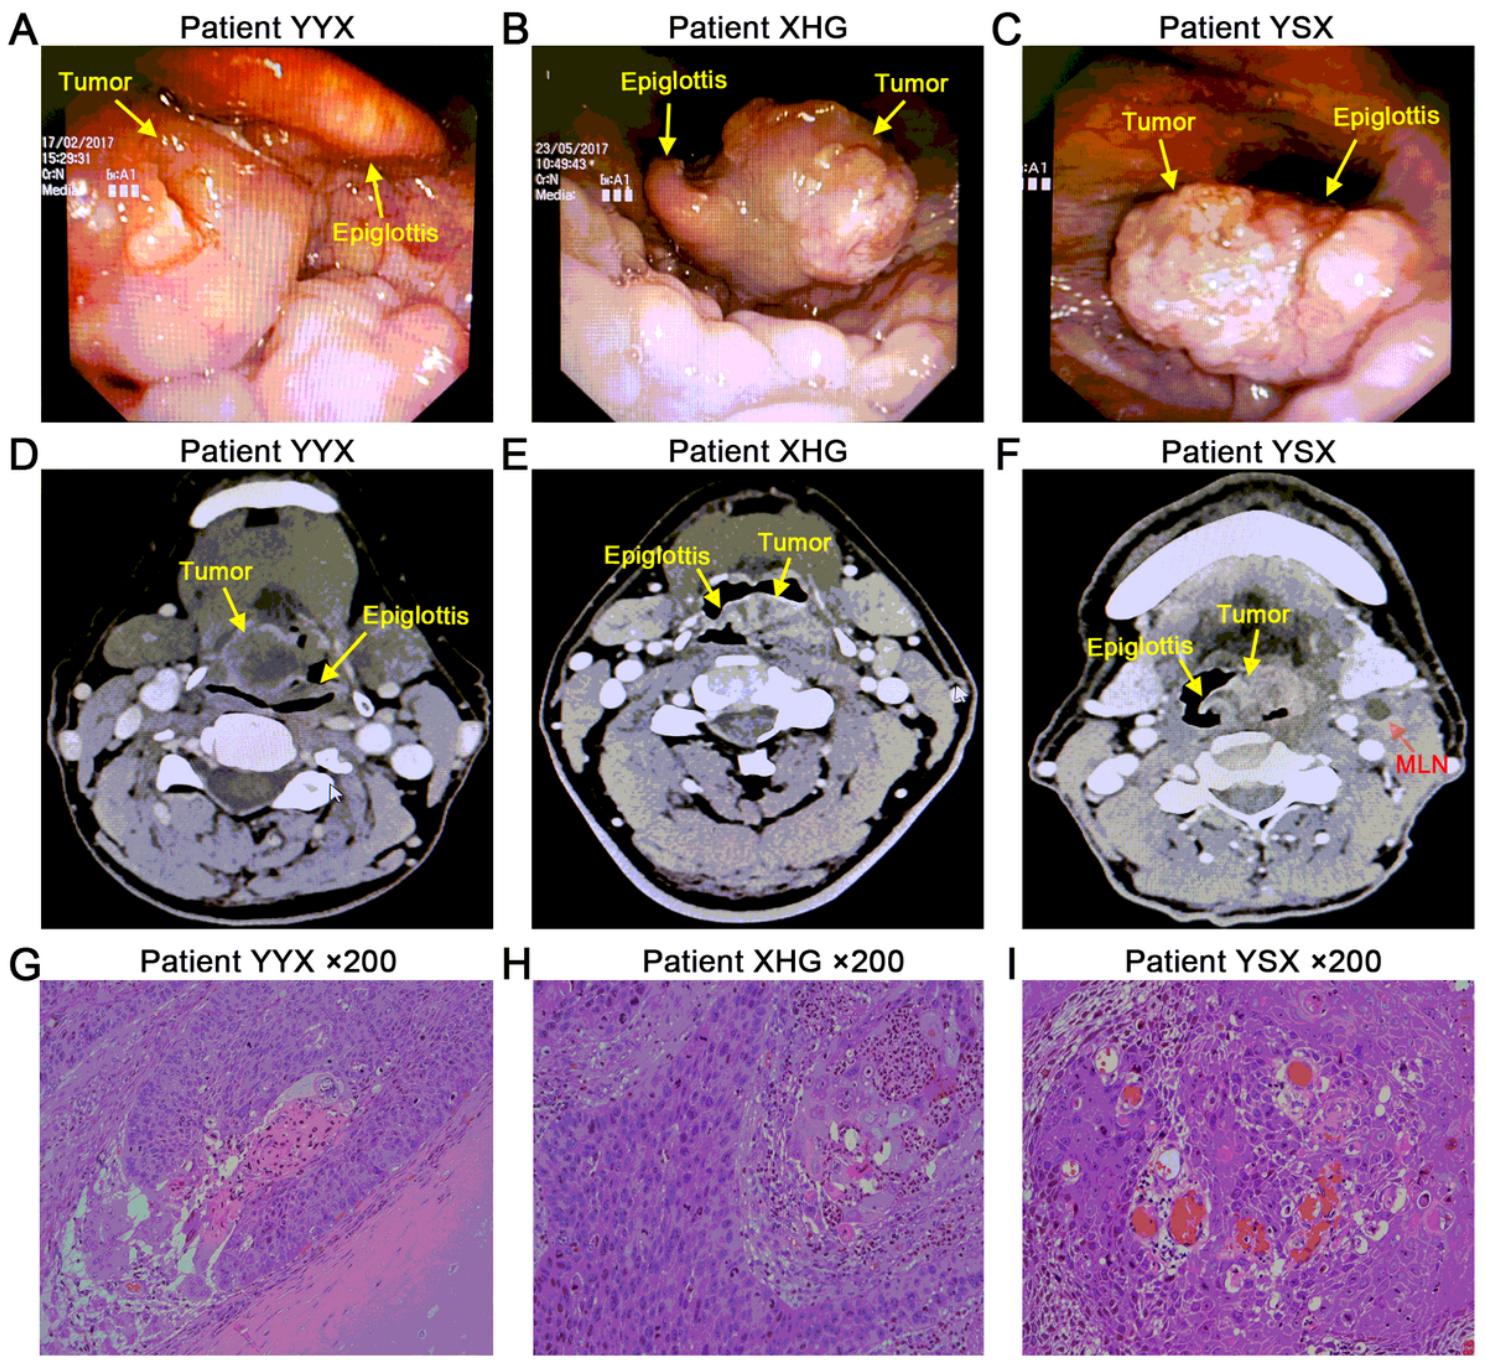

Figure 1

Laryngoscopy, contrast-enhanced CT and pathology of tumours from patients with SLSCC. Typical laryngoscopic photos of tumours from patients (a) YYX, (b) XHG and (c) YSX. All the tumours in three patients originated from the epiglottis. Typical CT images of tumours from patients (d) YYX, (e) XHG and (f) YSX. An obvious metastatic lymph node (MLN) with liquefactive necrosis was observed in the left neck near the submandibular gland in patient YSX. Typical pathological images of tumours from patients (g) YYX, (h) XHG and (i) YSX. All three tumours were moderately differentiated squamous cell carcinomas.

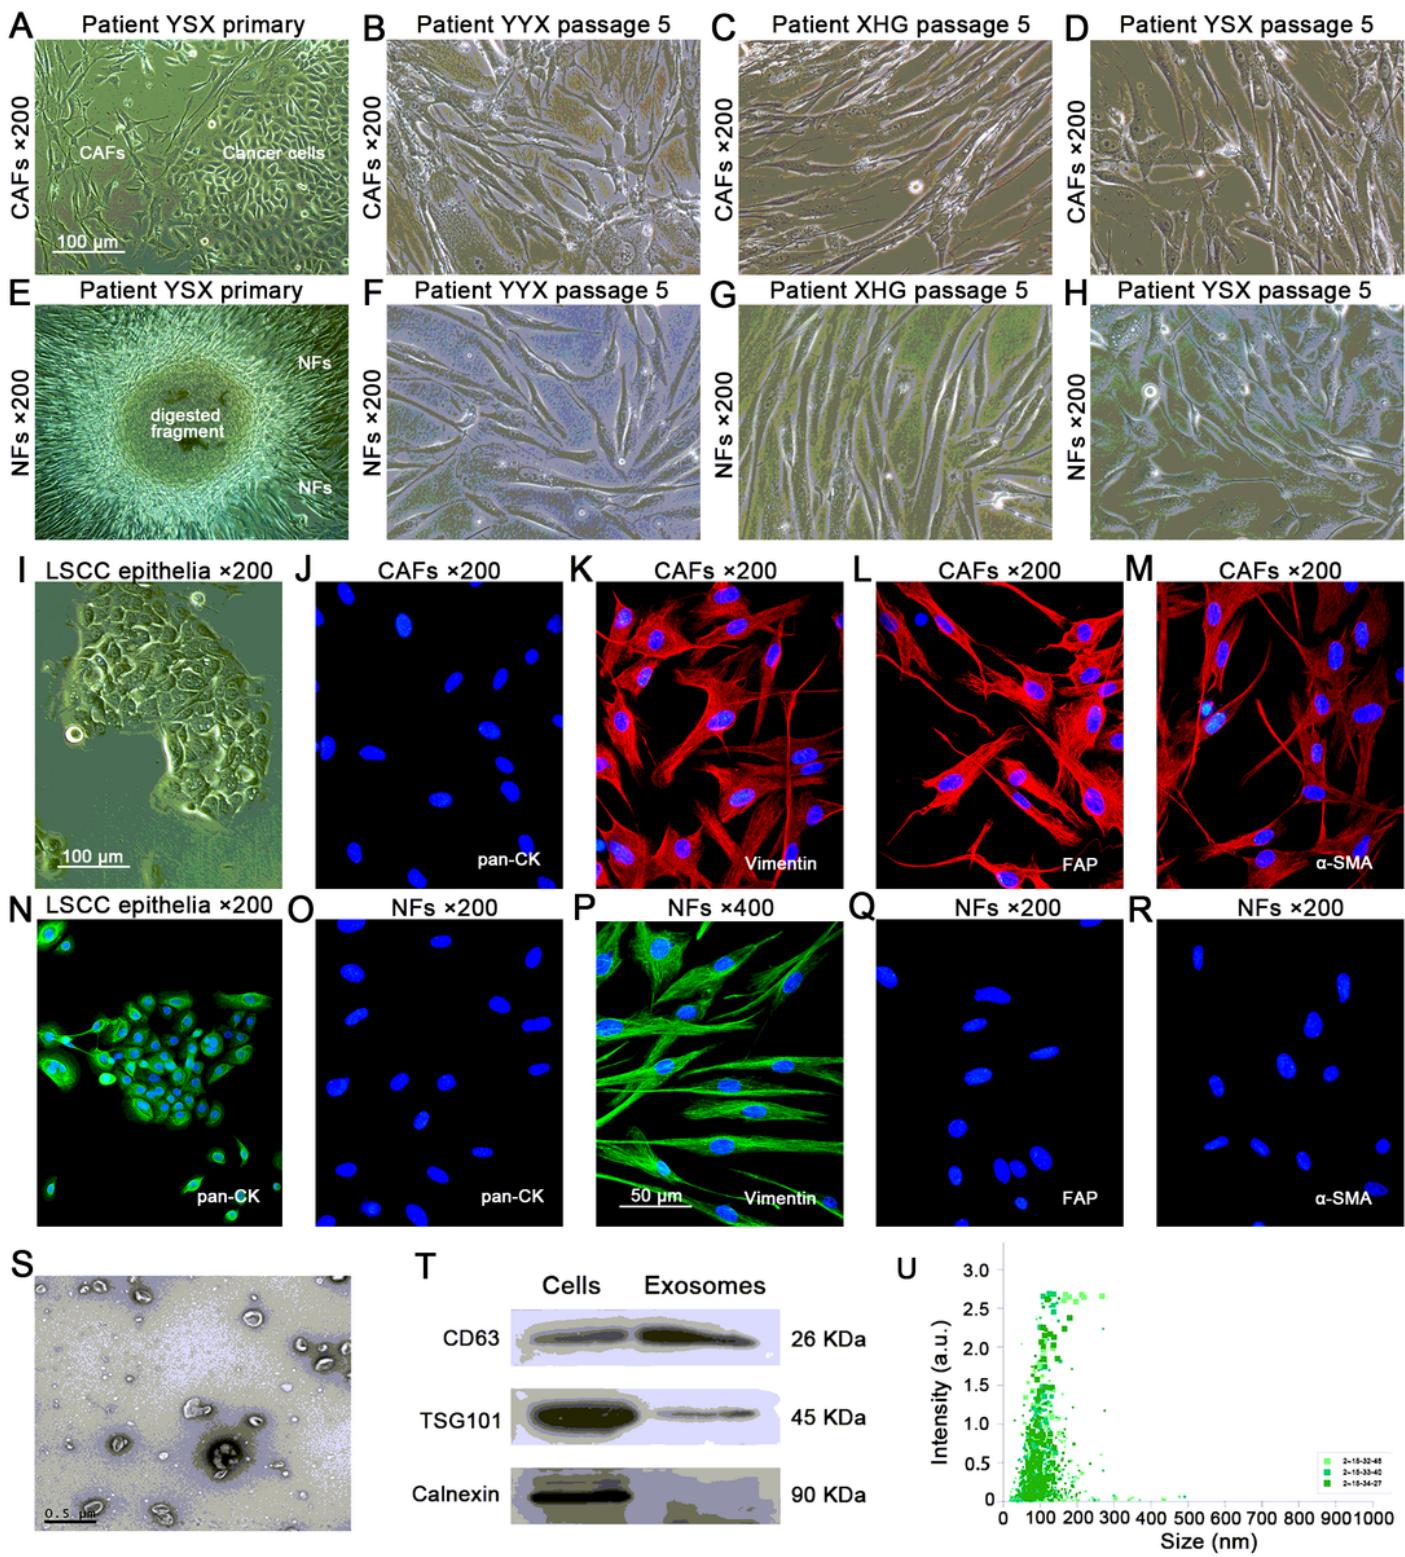

Figure 2

Morphology and immunofluorescence of CAFs and NFs and identification of exosomes. a Primary CAFs co-existed with cancer cells. b-d Purified CAFs at passage 5 from 3 patients. e Primary NFs grew out from the collagenase-digested fragments. f-h Purified paired NFs at passage 5; the NFs showed fewer cell prominences compared to the CAFs. i Morphology of LSCC epithelia. j-m CAFs showed negative staining for pan-CK and positive staining for vimentin, FAP and α-SMA. n Positive control of pan-CK. o-r NFs

showed negative staining for pan-CK, FAP and α -SMA and positive staining for vimentin. s-u TEM images, western blots and NTA data for exosomes.

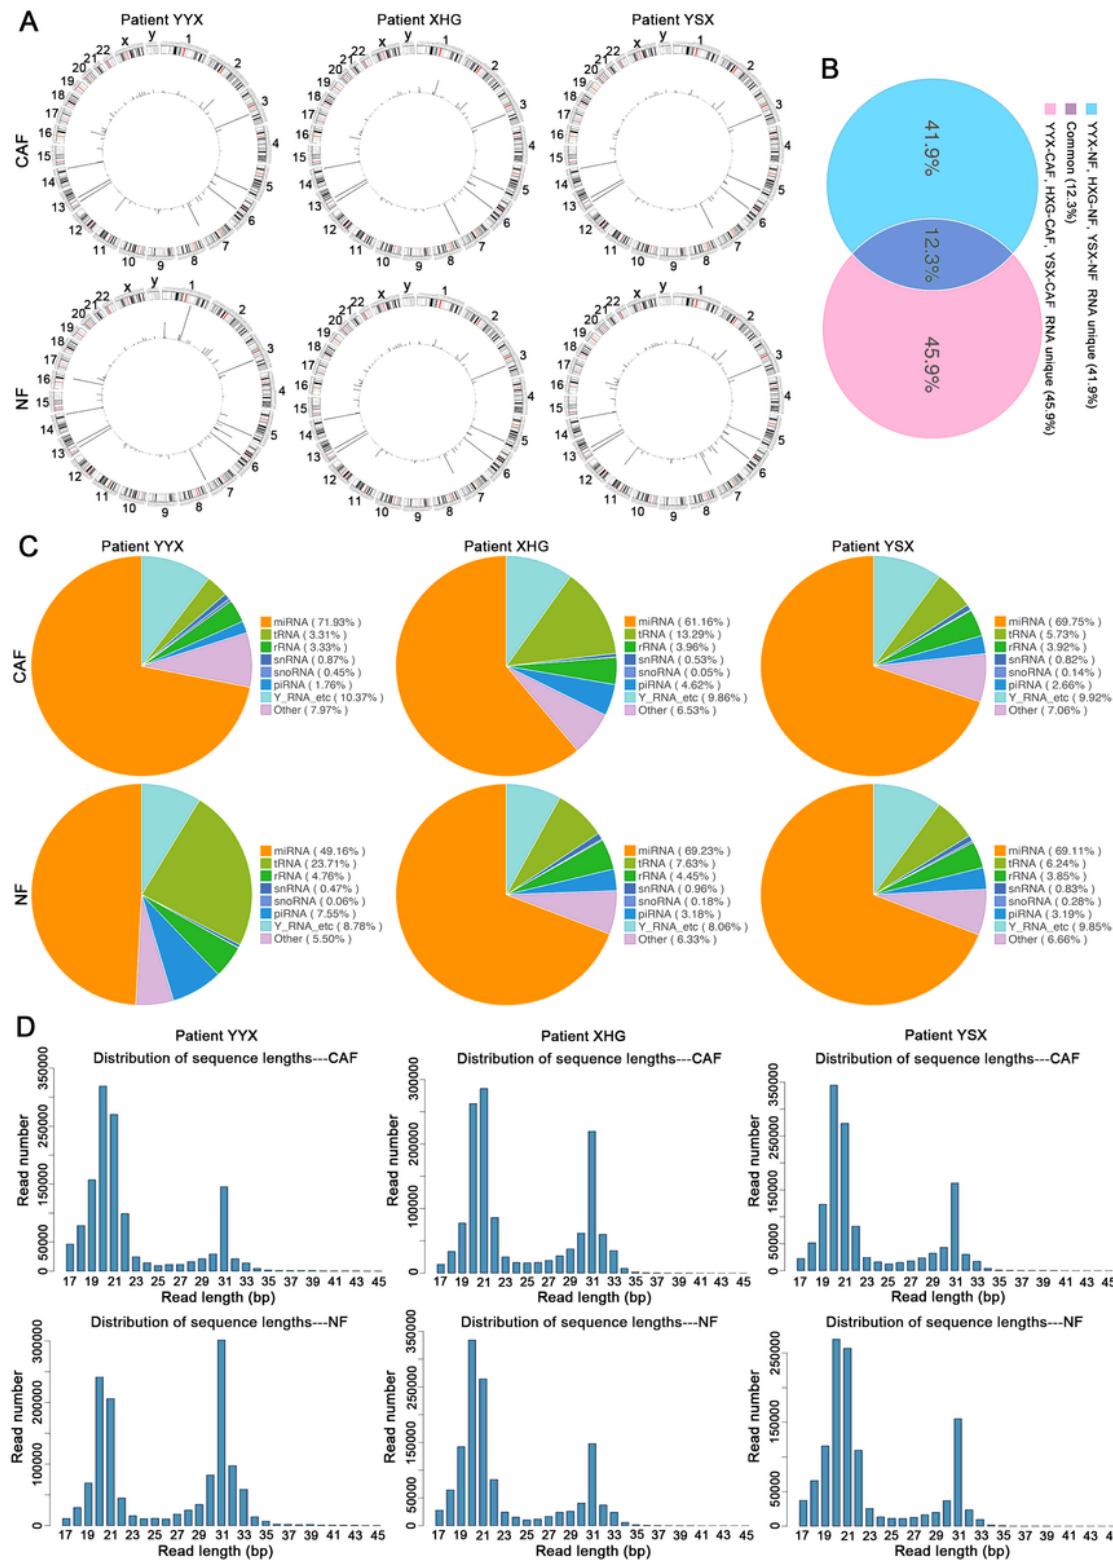

Figure 3

Different small RNA signatures of the exosome compartments and distribution of sequence lengths. a Sample read distribution in the whole genome illustrated by circos plots. The outer ring displays the ID of each chromosome, and the inner ring shows the abundance of RNA in the chromosomal region. The

small RNAs mainly originated from chromosomes 3, 5, 6, 7, 13 and 14. b Illustration of common and unique sequence data in exosomes. c Distributions of small RNA categories in exosomes, illustrated as pie charts. The main identified RNAs in the total small RNA distributions are miRNAs, tRNAs, rRNAs, snRNAs and snoRNAs. d Distribution of sequence lengths of exosomal RNAs. Most sequenced small RNAs were approximately 20 nt and 31 nt (clean reads) in size.

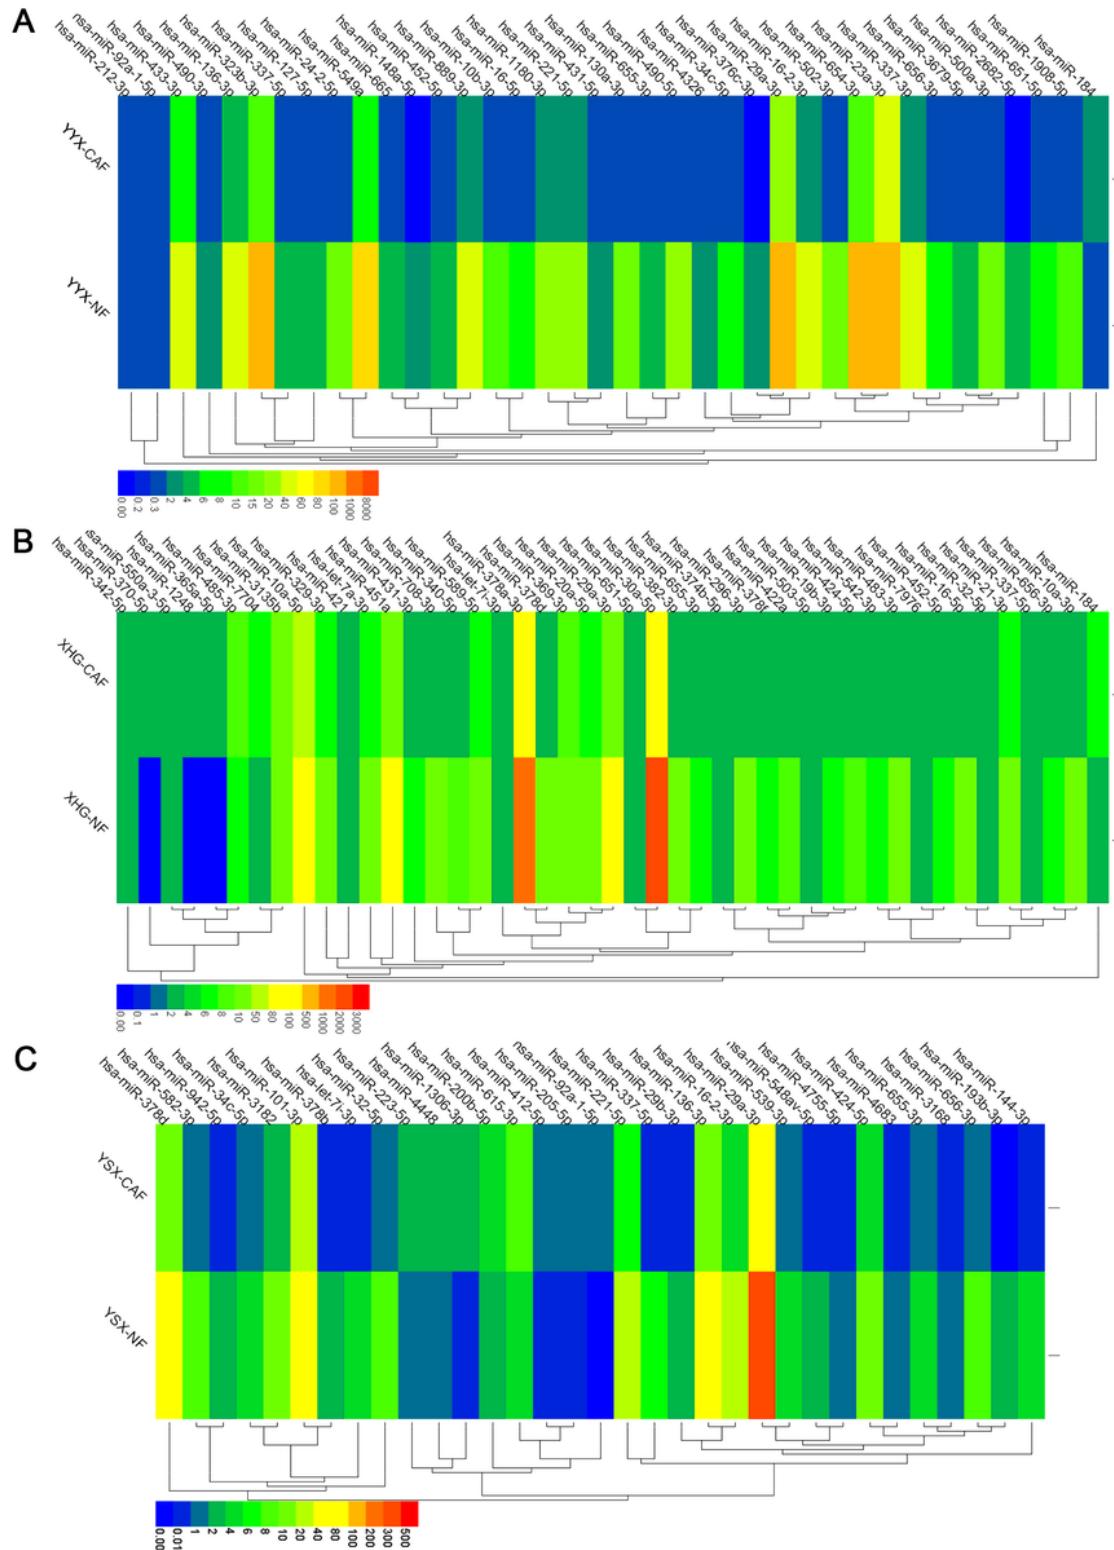

Figure 4

Dysregulated expression profiles of exosomal miRNAs between CAFs and NFs (CAF/NF) illustrated by heat maps. The fold change of log2 served as an inclusion criteria in either direction. Red signal: relative high expression; blue signal: relative low expression. a Patient YYX had 3 miRNAs that were upregulated and the other 42 were downregulated. b Patient XHG had 9 miRNAs that were upregulated and 36 that were downregulated. c Patient YSX had 8 miRNAs that were upregulated and 25 that were downregulated ($P<0.05$).

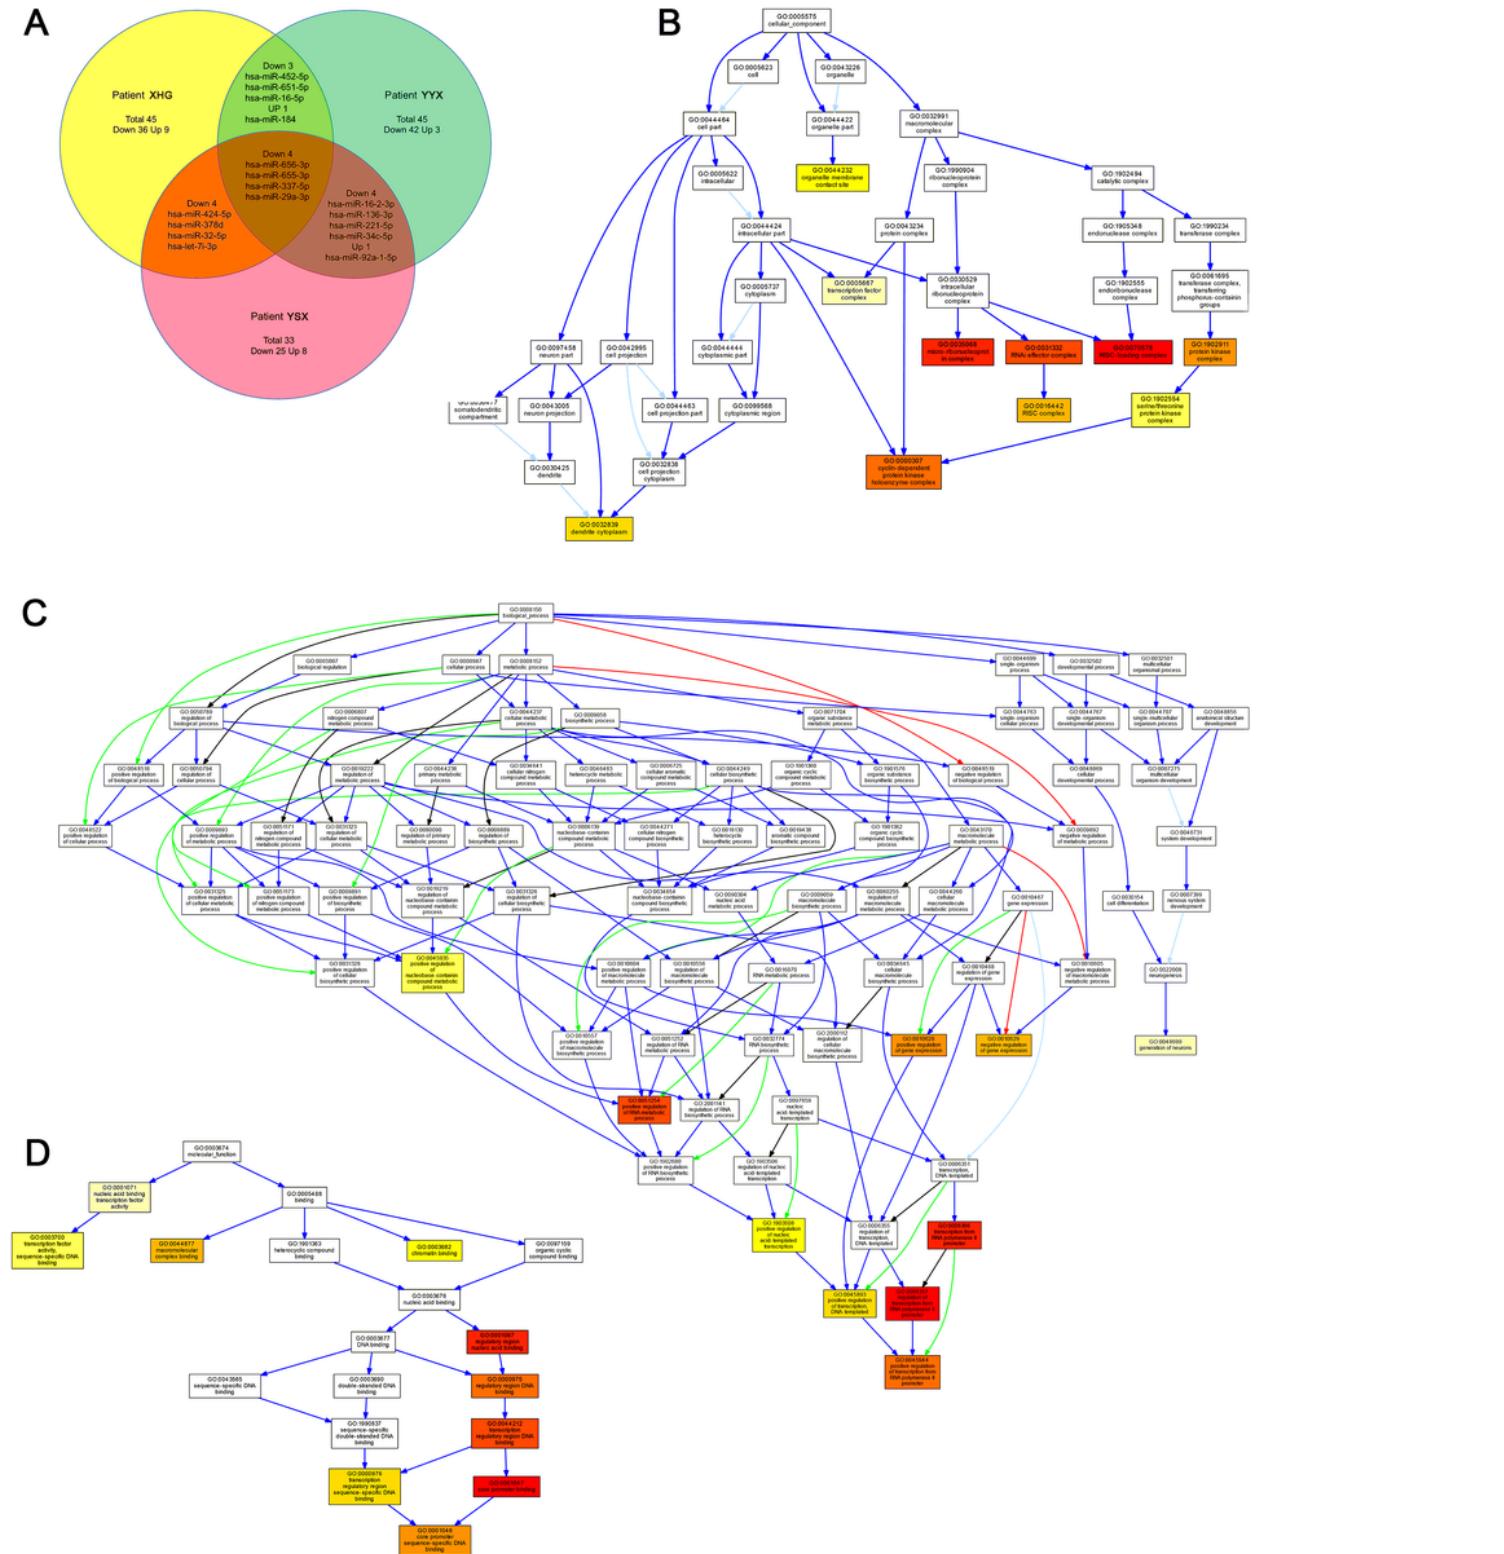

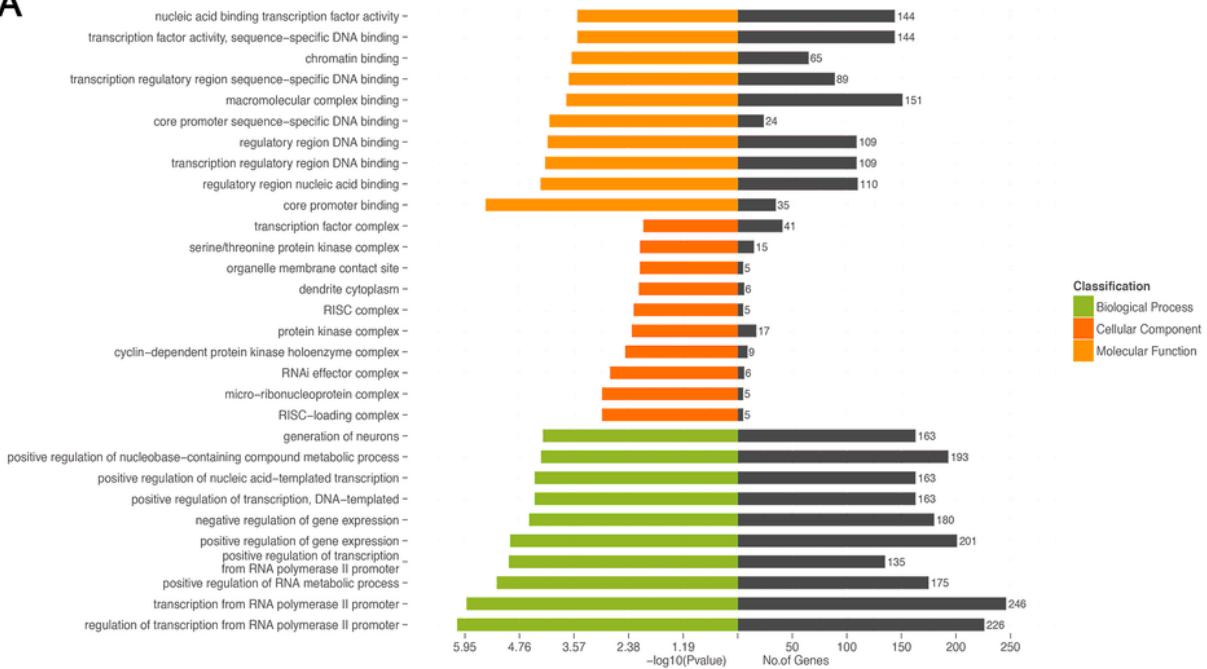

Figure 5

Illustration of dysregulated exosomal miRNAs from three patients with SLSCC and GO annotation of predicted targets. a Three miRNAs were downregulated and 1 miRNA was upregulated in both patient XHG and patient YYX; Four miRNAs were downregulated in both patient XHG and patient YSX; Four miRNAs were downregulated and 1 miRNA was upregulated in both patient YSX and patient YYX. Four miRNAs were downregulated simultaneously in all three patients. b-d The GO terms were involved in 3 categories: biological process, cellular component and molecular function ($P < 0.05$).

A

B

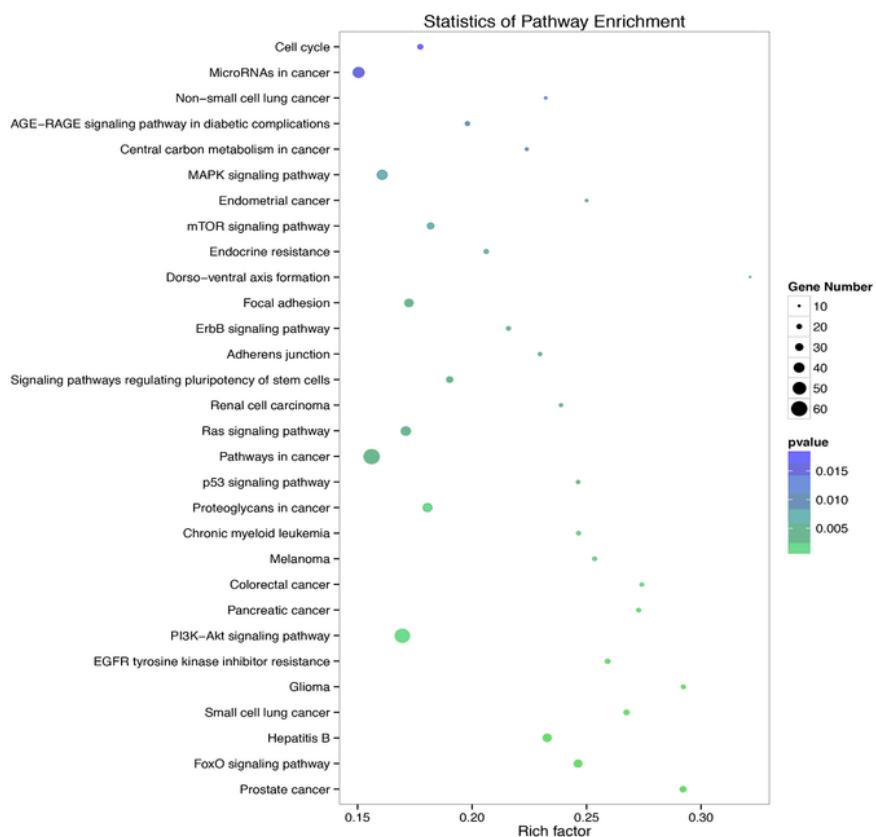

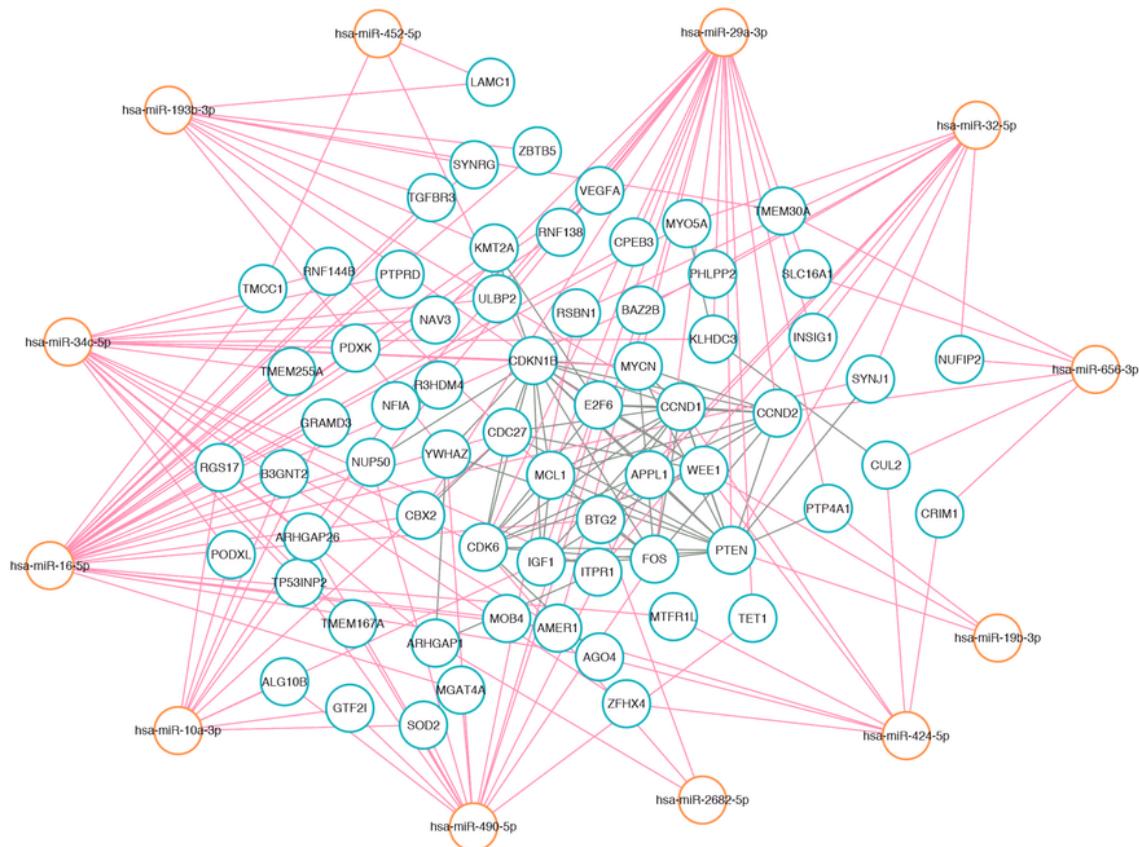

Figure 6

The top ten GO terms in three categories and KEGG pathway enrichment analysis. a The top 10 GO terms are illustrated for the three GO categories (biological process, cellular component and molecular function) ($P < 0.05$). b Thirty signal pathways with greatest statistical differences were selected for the KEGG analysis ($P < 0.05$).

A

B

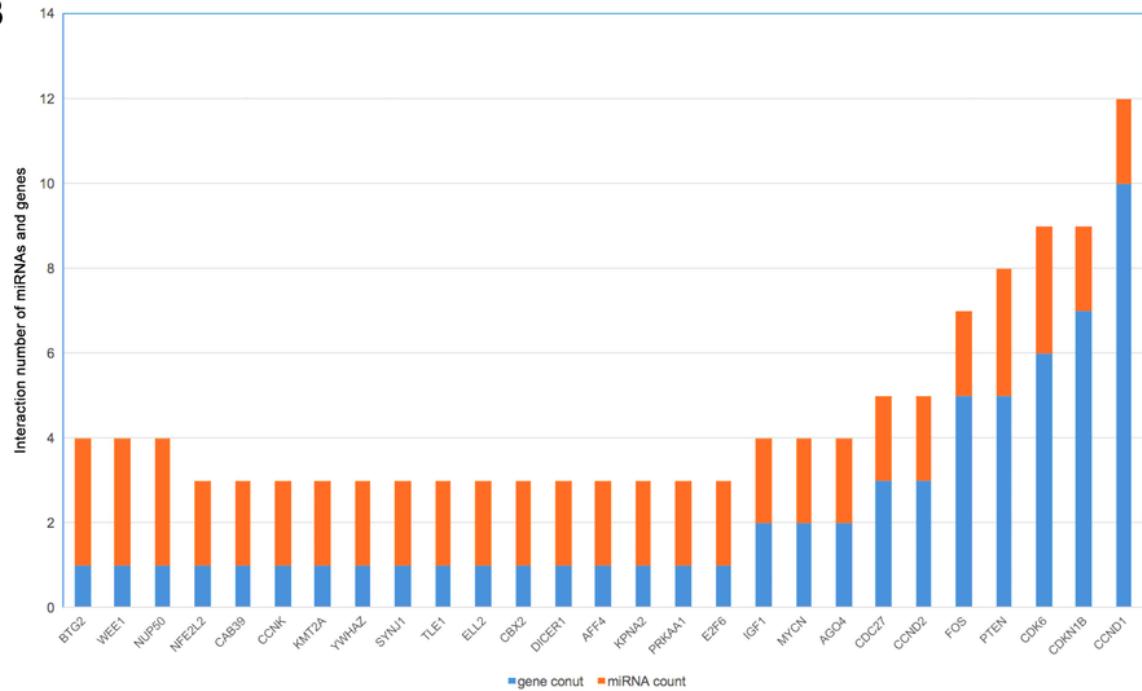

Figure 7

Interaction network of exosomal miRNAs and target genes. a The network revealed the interactions between 12 selected exosomal miRNAs and target genes determined by Cytoscape. b The interaction number of the selected genes with upstream miRNAs and downstream target genes. The orange bars represent the number of upstream miRNAs that regulate the present gene (such as CCND1, 2 upstream miRNAs). The blue bars indicate the number of downstream target genes that interacted with the present gene (such as CCND1, 10 downstream target genes).
