## ABSTRACT:

Since January 2020, some studies have been reporting a reduction in air pollution in several countries due to social isolation measures, which have been adopted in order to contain the coronavirus outbreak progress (Covid-19). This study aims to evaluate the change in the atmospheric pollution levels by NO and NO<sub>2</sub> in São Paulo city in the social isolation period. The NO and NO<sub>2</sub> hourly concentrations were obtained through air quality monitoring stations from CETESB, from January 14 to April 12, 2020. Mann-Kendall and the Pettitt tests were performed in the air pollutants time series. We observed an overall negative trend in all stations, indicating a decreasing temporal pattern in concentrations. Regarding NO, the highest decrease rates were observed in Congonhas (-6.39  $\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ ) and Marginal Tietê (-6.19  $\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ ) stations; Regarding NO<sub>2</sub>, the highest rates were observed in Marginal Tietê (-4.45  $\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ ) and Cerqueira César (-4.34  $\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ ) stations. In addition, we identified a turning point in the NO and NO<sub>2</sub> series trends that occurred close to the start date of the social isolation period (March 20, 2020). Moreover, from statistical analysis, it was found that NO<sub>2</sub> is a suitable surrogate for monitoring economic activities during social isolation period. Thus, we concluded that social isolation measures implemented in March 20, 2020 caused significant changes in the air pollutants concentrations in São Paulo city (as high as -200% in NO<sub>2</sub> levels).

**Keywords:** Air pollution, NO<sub>2</sub>, Coronavirus outbreak, COVID19, São Paulo.

## 1. INTRODUCTION

The population increase in urban centers causes serious environmental problems, among which the degradation of air quality stands out due to the emission of air pollutants by internal combustion engines (Aleixo and Neto 2009; Cetin et al. 2019). Such air pollutants may come from mobile or stationary sources. It is noteworthy that in highly urbanized regions, such as the São Paulo Metropolitan Area (SPMA), the main source of air pollutant emissions is the vehicle fleet. According to the official emissions inventory, SPMA mobile sources in 2017 were responsible for 97% of carbon monoxide (CO) emissions, 75% of hydrocarbons (HC), 64% of nitrogen oxides (NO<sub>x</sub>), 17% of sulfur oxides (SO<sub>x</sub>) and 40% of particulate material (MP<sub>10</sub>) to the atmosphere (Cetesb 2020).

According to World Health Organization (WHO) data, 91% of the world's population breathes polluted air (WHO 2016) which causes thousands of deaths each year from heart disease, lung cancer, stroke and acute and chronic respiratory diseases. The Southern region of Brazil is the most affected area regarding air pollution, especially São Paulo State due to its demographic features, since it has almost 46 million inhabitants. From this total, almost 25% resides in São Paulo city in an area of 1,521 km<sup>2</sup>, associated with the largest vehicle fleet in the country, exceeding 8 million vehicles (~ 90% light vehicles) according to 2019 IBGE's data (Dapper et al. 2016; Silva et al. 2017; Koga et

**\*Correspondence author:** Marcelo Vieira da Silva Filho (marcelo.filho@ufla.br), phone: (+55)11-9 8598 6567

36 al. 2020; Ministério da infraestrutura 2020). Given this perspective, the emission of NO (nitrogen monoxide) and NO<sub>2</sub>  
37 (nitrogen dioxide), which are pollutants derived directly from the burning of fossil fuels, stands out (Ribas et al.,  
38 2016). Regarding NO<sub>x</sub> levels, NO<sub>2</sub> can also be formed in the atmosphere from chemical reactions of NO with  
39 oxidizing compounds, which implies higher concentrations of nitrogen dioxide in urban zones (Casquero-Vera et al.  
40 2019; Yao et al. 2019; Zhang et al. 2020).

41 In early 2020, several nations adopted social isolation measures in order to contain the advance of the  
42 Coronavirus outbreak (Covid-19), categorized in China as Sars-CoV-2 (Andersen et al. 2020; Chean and Lanjuan  
43 2020) and which has a high rate of transmission and contagion. The same measure was adopted in the city of São  
44 Paulo from the first half of March (Sanar Saúde 2020), leading to the closure of universities, institutions and commerce  
45 lockdown in order to reduce contagion (São Paulo 2020). However, we should note that adherence to isolation was  
46 not widespread and varied from one location to another in São Paulo city (Revista Veja 2020).

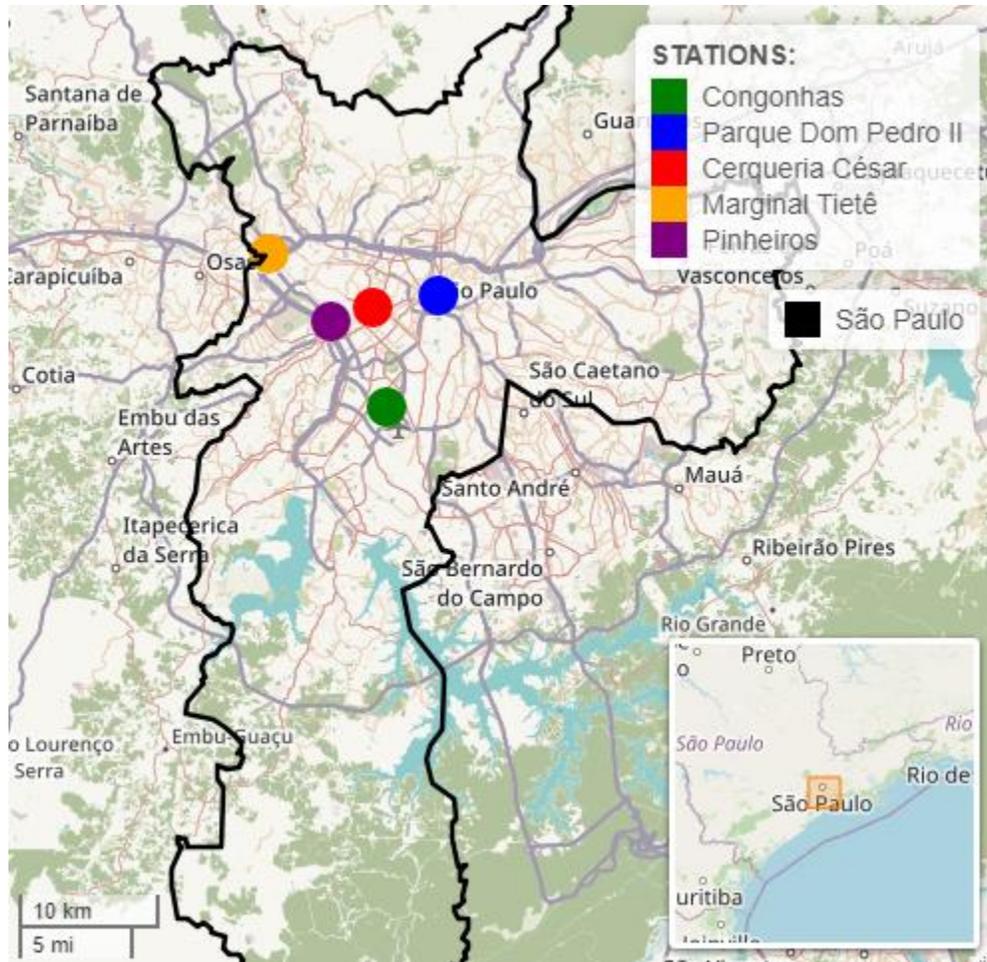

47 The social isolation caused a decrease in vehicular traffic and industrial activities, which consequently  
48 changed the pattern of emissions of atmospheric pollutants. In a recent study, it was found that carbon and NO<sub>2</sub>  
49 emissions in China were reduced by 30 and 25%, respectively, after the beginning of isolation measures (Isaifan  
50 2019). Based on this perspective, this study has the objective to evaluate the changes caused by the period of social  
51 isolation in relation to NO and NO<sub>2</sub> emissions in the city of São Paulo, in order to determine whether such measures  
52 were representative and mathematically significant.

## 53 2. MATERIALS AND METHODS

### 54 2.1. Characterization of the Study Region

55 The municipality of São Paulo is located in the southeast portion (23.5477°S; 46.6336° W) of the state  
56 of São Paulo and has a territorial area equal to 1,521 km<sup>2</sup> (Figure 1). In population estimative for July 2019,  
57 São Paulo is classified as the most populated municipality in Brazil, with 12.25 million inhabitants (IBGE,  
58 2019; ZERI et al., 2016). Economically, it presents a large industrial district, dominated mainly by food,  
59 chemical and oil industries. Its vehicle fleet, in March 2020, were composed of 8.631 million vehicles, of which  
60 5,902,755 (88%) were automobiles and 1,022,157 (12%) were motorcycles. It is important to highlight that a  
61 large part of the flow of vehicles in São Paulo is due to neighboring cities in the so-called São Paulo  
62 Metropolitan Area (SPMA), increasing the number of vehicles and traffic jam. The SPMA vehicle fleet were  
63 about 13,908,845 vehicles, of which 9,394,570 (68%) were automobiles and 4,514,275 (32%) were  
64 motorcycles, for the same period. (INVESTSP, 2020; Ministério da Infraestrutura, 2020).

65 It is also worth mentioning that the region is surrounded by Serra da Cantareira and Serra do Mar,  
66 which reaches 700 – 1000m elevation. In the summer, the South Atlantic Convergence Zone (SACZ) and the  
67 Mesoscale Convective Systems (SCM) are main drivers for precipitation and greater atmospheric instability. In  
68 winter, due to the reduction of precipitation and the occurrence of thermal inversions, the atmosphere tends to  
69 acquire a greater stability, which causes the stagnation of atmospheric pollutants from industrial activities and  
70 from the burning of fuels in the lower atmospheric layers and near the surface (Vieira-Filho et al. 2015; Segalini  
71 et al. 2016; Zeri et al. 2016).

72

73 **Figure 1** – Geographic delimitation of the study area (São Paulo municipality) and location of the stations  
 74 used in the study.

## 75 2.2. Atmospheric pollutants (NO<sub>x</sub>)

76 Data of nitrogen monoxide (NO) and nitrogen dioxide (NO<sub>2</sub>) were retrieved from air quality  
 77 monitoring stations, operated by São Paulo environmental agency (CETESB, 2020) in hourly resolution. For  
 78 this study, we considered the period between January 14 and April 12 (2020), with a maximum number of 90  
 79 daily observations. We selected the following air quality monitoring stations: Cerqueira César, Pinheiros,  
 80 Congonhas, Parque Dom Pedro II and Marginal Tietê due to the availability of validated measures. Information  
 81 regarding each station are represented in Table 1.

82

83

84

85 **Table 1** – Geographic location of air quality monitoring stations, number of data available and data series  
 86 representativity.

| STATION             | LONGITUDE | LATITUDE | CODE | n  | %   |
|---------------------|-----------|----------|------|----|-----|
| Cerqueira César     | -46.67    | -23.55   | 91   | 86 | 95  |
| Congonhas           | -46.66    | -23.61   | 73   | 90 | 100 |
| Marginal Tietê      | -46.74    | -23.51   | 270  | 90 | 100 |
| Parque Dom Pedro II | -46.62    | -23.54   | 72   | 90 | 100 |
| Pinheiros           | -46.70    | -23.56   | 99   | 89 | 98  |

87 “n” – number of observations; “%” – the percentage of data series representativity

### 88 2.3. Statistical Analysis

89 We performed the statistical treatment of the data with the use of programming in R language, through  
 90 the RStudio interface, using the packages *openair* (Carslaw and Ropkins 2012), *lubridate* (Grolemund and  
 91 Wickham 2011), *trend* (Pohlert 2020) and *ggplot2* (Wickham et al. 2020).

92 From the data collected, we performed the following tests: Mann-Kendall, Slope and Pettitt.

#### 93 Mann-Kendall Test

94 The Mann-Kendall (MK) test aims to identify trends in time series (Wilks 2005). The equations we  
 95 use are the following:

$$S = \sum_{i=1}^{n-1} \sum_{j=i+1}^n \mathbf{sign}(X_j - X_i) \quad (1)$$

96 "X" represents the values of the series; "i" and "j" are the time indices and "n" is the number of elements  
 97 of the series.

$$\mathbf{sign}(X_j - X_i) = \begin{cases} +1 & \text{se } (X_j - X_i) > 0 \\ 0 & \text{se } (X_j - X_i) = 0 \\ -1 & \text{se } (X_j - X_i) < 0 \end{cases} \quad (2)$$

98 We also calculate the mean and variances (Equations 3 and 4):

$$E(S) = \frac{n(n-1)}{4} \quad (3)$$

99

$$VAR(S) = \frac{n(n-1)(2n+5)}{72} \quad (4)$$

100

101 The significance of the MK test was performed through a bilateral test, with standardized statistics Z  
102 (Equation 5).

$$Z = \begin{cases} \frac{S-1}{\sqrt{Var(S)}} & \text{se } S > 0 \\ 0 & \text{se } S = 0 \\ \frac{S+1}{\sqrt{Var(S)}} & \text{se } S < 0 \end{cases} \quad (5)$$

103 We emphasize that the statistical significance was validated through the value of p. The null hypothesis  
104 tested predicts no trend in the timeseries.

#### 105 Sen's slope analysis

106 Following the Mann-Kendall test, we determine the value of the slope (Equation 6), from which we  
107 determine the magnitude of temporal trends is given (Sen 1968; Salarijazi et al. 2012).

$$\beta = \text{Median} \left( \frac{X_j - X_i}{j - i} \right) \text{ com } i < j \quad (6)$$

108

109 "X<sub>i</sub>" and "X<sub>j</sub>" represent the values of the variable under study in positions "i" and "j". Positive or  
110 negative values for β indicate increasing or decreasing trends.

#### 111 Pettitt Test

112 In the following, we applied the Pettitt test (Equations 7, 8 and 9) in order to identify discontinuity  
113 points in the data series (Pettitt 1979).

$$U_{t,T} = U_{t,T} + \sum_{j=1}^T \text{ sinal}(Y_i - Y_j) \quad (7)$$

114 Where:

$$\text{Sinal}(Y_i - Y_j) = \begin{cases} +1, \text{ se } (Y_i - Y_j) > 0 \\ 0, \text{ se } (Y_i - Y_j) = 0 \\ -1, \text{ se } (Y_i - Y_j) < 0 \end{cases} \quad (8)$$

115 This statistic makes it possible to locate the point where there was a sudden change in the series  
 116 pattern ( $K_{crit}$ ), at "t" position.

$$K_{crit} = \pm \sqrt{\frac{-\ln(P/2) (T^3 + T^2)}{6}}, \text{ com } p = 2e^{\frac{-6K^2(t)}{(T^3+T^2)}} \quad (9)$$

117 We emphasize that the null hypothesis of the test is that there is no sudden change in the series. In this  
 118 study, we applied the Pettitt test in two periods: P1 - complete series (Jan, 14<sup>th</sup> – April, 12<sup>th</sup>) and P2 - partial  
 119 series (Mach, 1<sup>st</sup> - April, 12<sup>th</sup>), in order to verify the point of change. The purpose of this methodology was to  
 120 verify if significant intervention point is closer to the isolation measures. If it was not, the Pettitt test is repeated  
 121 for a more restricted period (P2).

### 122 3. RESULTS AND DISCUSSION

123 In order to verify trends in the nitrogen monoxide (NO) and nitrogen dioxide (NO<sub>2</sub>) series, we applied  
 124 the Mann-Kendall and Pettitt tests for the five air quality monitoring stations. The results are presented in tables  
 125 2 and 3.

126 **Table 2** - Results of statistical analyses (MK, value of Sen and Pettitt) related to NO.

| STATION             | n  | Value of Sen<br>$\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ | P1<br>(01/14 – 04/12) | P2<br>(03/01 – 04/12) |
|---------------------|----|---|-----------------------|-----------------------|
| Cerqueira César     | 86 | -2.60   | 02/26                 | 03/21                 |
| Congonhas           | 90 | -6.39   | 03/06                 | 03/22                 |
| Marginal Tietê      | 90 | -6.19   | 02/26                 | 04/04                 |
| Parque Dom Pedro II | 90 | -1.59   | 02/29                 | 03/21                 |
| Pinheiros           | 89 | -3.19   | 03/20                 | -                     |

127 "n": number of daily data for the period from January 12<sup>th</sup> to April 14<sup>th</sup>, 2020; "p<sub>1</sub> and p<sub>2</sub>": points of intervention  
 128 found.

129 From the data, we verified statistically significant trends in NO and NO<sub>2</sub> levels in all the analyzed  
 130 stations, since they presented a p value of less than 5% in the MK test (Folhes and Fisch 2006; Cukurluoglu  
 131 and Bacanlı 2018). Also, we calculated the value of Sen in order to verify the magnitude (growth/decrease) of  
 132 the trend of the series (Chaudhuri and Dutta 2014) and we observed that the values of Sen, without exception,  
 133 were all negative, which indicates decrease patterns from January to April 2020. These results suggest that the  
 134 concentrations, in  $\mu\text{g}\cdot\text{m}^{-3}$ , of NO and NO<sub>2</sub> decreased in the period of Jan, 14<sup>th</sup> - April, 12<sup>th</sup> at the monthly rate  
 135 presented by third columns of tables 2 and 3.

136

137

138

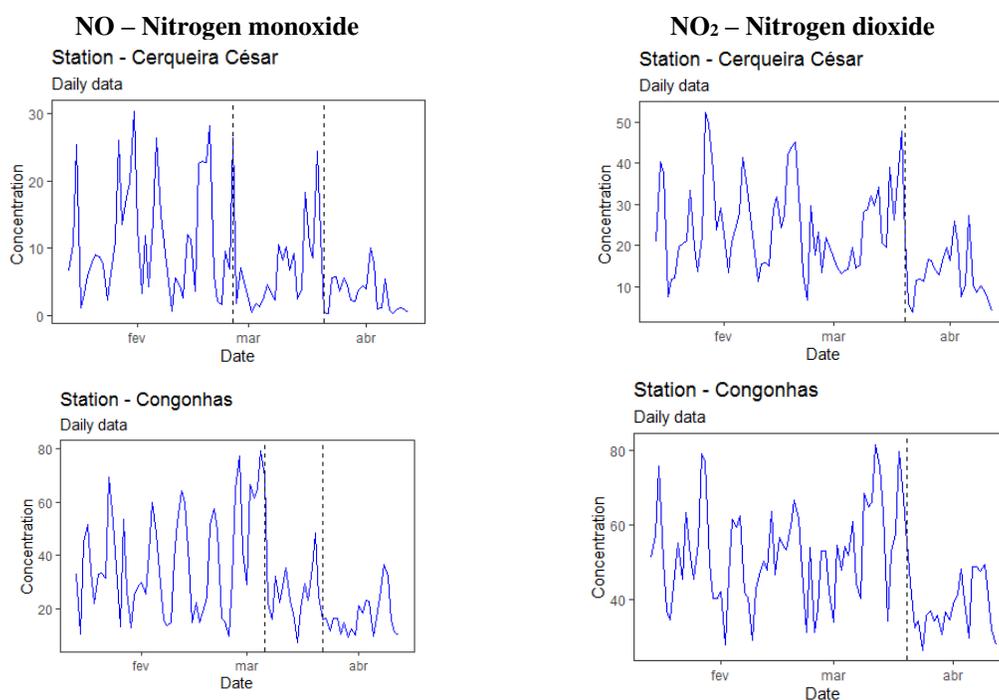

139 **Table 3** - Results of statistical analysis (MK, value of Sen and Pettitt) related to NO<sub>2</sub>.

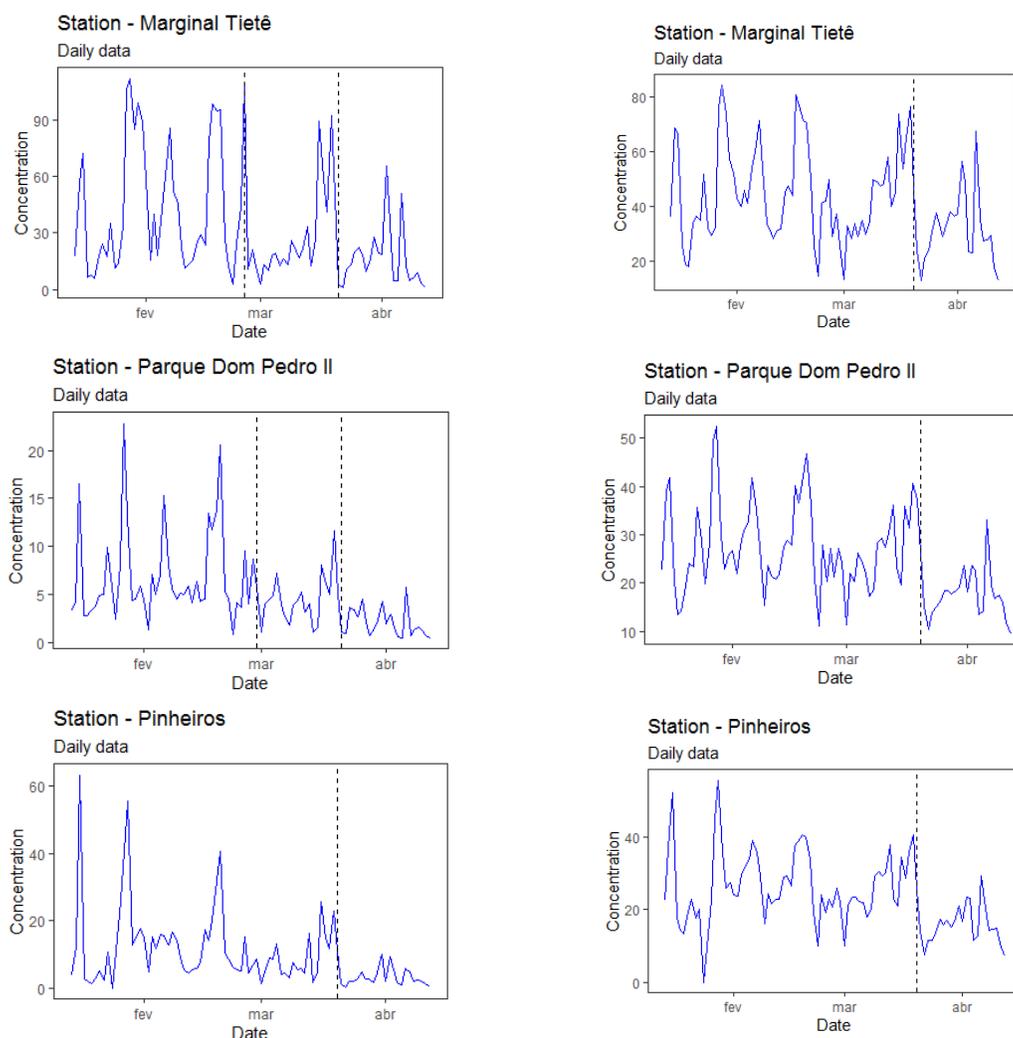

| STATION             | n  | Value of Sen<br>$\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ | P1<br>(01/14 – 04/12) | P2<br>(03/01 – 04/12) |
|---------------------|----|---|-----------------------|-----------------------|
| Cerqueira César     | 86 | -4.34   | 03/20                 | -                     |
| Congonhas           | 90 | -3,78   | 03/20                 | -                     |
| Marginal Tietê      | 90 | -4.45   | 03/20                 | -                     |
| Parque Dom Pedro II | 90 | -3.68   | 03/20                 | -                     |
| Pinheiros           | 89 | -4.11   | 03/20                 | -                     |

140 "n": number of daily data for the period from January 12<sup>th</sup> to April 14<sup>th</sup>, 2020; "P<sub>1</sub> and P<sub>2</sub>": points of intervention  
 141 found.

142 Moreover, columns "P1" and "P2" show the intervention points determined by the Pettitt test  
 143 (Salarizaji et al. 2012; Ferreira et al. 2015; Jaiswal et al. 2015; Ahmad et al. 2018; Penereiro and Meschiatti  
 144 2018; Gaponov et al. 2019) for each period. In order to visualize the decreasing trends and the intervention  
 145 points, we have elaborated the Figure 2.

146

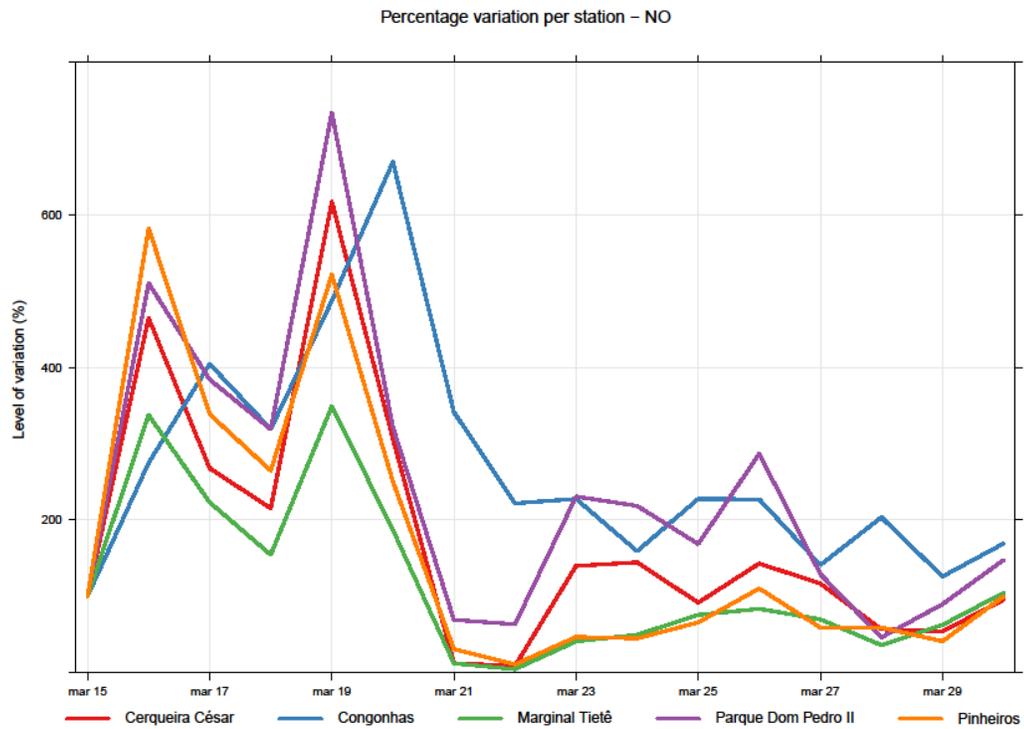

147 *Note: the dashed vertical lines indicate the intervention points determined via Pettitt's test.*

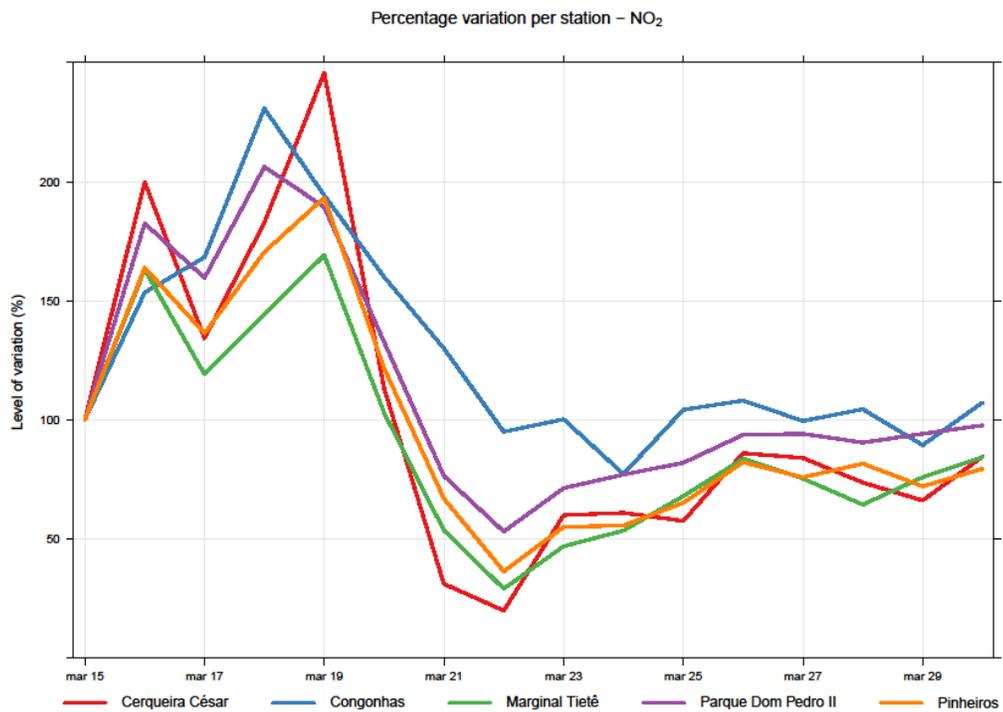

148 **Figure 2** - Time series of daily mean NO and NO<sub>2</sub> concentration, in units of  $\mu\text{g}\cdot\text{m}^{-3}$ , in the period between  
 149 January 14<sup>th</sup> and April 12<sup>th</sup>, 2020.

150 Regarding the intervention points for NO (Table 2), Pinheiros, Parque Dom Pedro II, Cerqueira César  
 151 and Congonhas stations presented changes in their trends near the quarantine start date (March, 20<sup>th</sup>). Assuming  
 152 that social isolation would cause a sharp decrease in vehicular flow in the municipality of São Paulo, it would  
 153 be expected that intervention points were close to the second half of March, which is also verified by P1 dates  
 154 from NO<sub>2</sub> (Table 3). NO<sub>2</sub> shows an even more sharp change (Figure 2) in comparison with NO. Although  
 155 emitted together with NO<sub>2</sub>, NO, has a short residence time, and a major species in photochemical smog that  
 156 culminates in NO<sub>2</sub> and O<sub>3</sub> species (Han et al. 2011; Salonen et al. 2019)

157 Although most intervention points were identified on dates closer to quarantine start date, an opposite  
 158 behavior was observed in NO concentrations observed in Cerqueira César (February, 26<sup>th</sup>) and Ibirapuera

159

160

161

**Figure 3 - Daily concentration percentage variation of NO (top) and NO<sub>2</sub> (bottom) in the period from March, 15<sup>th</sup> to March, 20<sup>th</sup> in 2020.**

162

163 (March, 6<sup>th</sup>) stations (Table 2). Several meteorological factors may influence the earlier intervention  
164 points by the Pettitt test (before quarantine). Among them, we emphasize the high rainfall volume in the São  
165 Paulo city in February 2020 (496.7mm), which is a 248% increase from the climatological value (200 mm,  
166 period 1981 – 2010) and also higher than the last 4 years (INMET, 2020). Among the implications of a high  
167 rainfall index, is the increase of scavenging air pollutants by wet deposition (Torres and MARTINS 2005;  
168 Shukla et al. 2008; Freitas and Solci 2009; Vieira-Filho et al. 2013; Yoo et al. 2014; Santos et al. 2019). Thus,  
169 given the high precipitation at the end of February, the NO concentrations were altered and, therefore, the  
170 identified intervention points were not close to the social isolation period.

171 A plot of the daily percentage variation of NO (Figure 3a) and NO<sub>2</sub> (Figure 3b) (Agustine et al. 2017;  
172 Silver et al. 2018) is depicted covering only the period from March, 15<sup>th</sup> to March, 30<sup>th</sup>, highlighting social  
173 isolation period (Koga et al. 2020).

174 Sharp decreases were observed in NO<sub>2</sub> and NO levels in Cerqueira César and Marginal Tietê stations  
175 from March, 19<sup>th</sup> and 20<sup>th</sup>. Cerqueira César station shows a reduction of -60% compared to average  
176 concentration on March, 15<sup>th</sup> in NO<sub>2</sub> levels. Furthermore, it is noteworthy that both stations (Cerqueira César  
177 and Marginal Tietê) are located in urban agglomeration points (urban terminals and bus lanes), moreover  
178 Marginal Tietê station is located in the vicinity of main interstate roadway where heavy vehicles commute.  
179 Furthermore, Cerqueira César station is located in a high population zone with commercial centers, museums,  
180 theaters and cultural institutions.

181 Some preliminary studies showed in Brazilian media such as IPEN (2020), emphasized the reductions  
182 of primary pollutants concentration levels in the social isolation period using satellite measurements for SPMA  
183 area. The reduction reported in these studies were up to 50%, however analyzing the air quality data stations  
184 we could observe that reductions in NO<sub>x</sub> levels as high as -200% from March, 19<sup>th</sup> to March, 21<sup>th</sup> in Cerqueira  
185 Cesar. Figure 3 also highlights the sharp decrease in NO and NO<sub>2</sub> concentrations on March, 20<sup>th</sup>, which is  
186 reasonable with the values of Sen Slope and also the interventions points (Tables 2 and 3). Pettitt test, associated  
187 to Mann-Kendall test, indicated a downward trend and anomalous behavior of the data daily series since  
188 quarantine started.

#### 189 4. CONCLUSION

190 Analyzing the NO and NO<sub>2</sub> levels from January to April 2020, we could observe statistically significant  
191 negative trends in São Paulo city, and the highest absolute rates were observed in Congonhas (-6.39  $\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ )  
192 and Marginal Tietê (-6.19  $\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ ) stations for NO; and Marginal Tietê (-4.45  $\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ )  
193 and Cerqueira César (-4.34  $\mu\text{g}\cdot\text{m}^{-3}\cdot\text{month}^{-1}$ ) stations for NO<sub>2</sub>. Assuming NO<sub>2</sub> decrease rates of Marginal Tietê  
194 and Cerqueira César stations at a standstill until the end of 2020, the total pollution reduction would be above  
195 9,500 tons in SPMA area.

196 In addition, it should be noted that the stations with the highest percentage reductions since March 15<sup>th</sup>  
 197 were Cerqueira César and Marginal Tietê. Moreover, we conclude that NO<sub>2</sub> is more suitable surrogate for  
 198 vehicle and economic activities than NO, due to Pettit statistical test.

199 We concluded that the social isolation measures as of March, 20<sup>th</sup> were sufficient to change the  
 200 dynamics of concentrations of atmospheric pollutants such as NO and NO<sub>2</sub> originating from the burning of  
 201 automobile fuels and from chemical reactions in the atmosphere.

# Figures

**Figure 1**

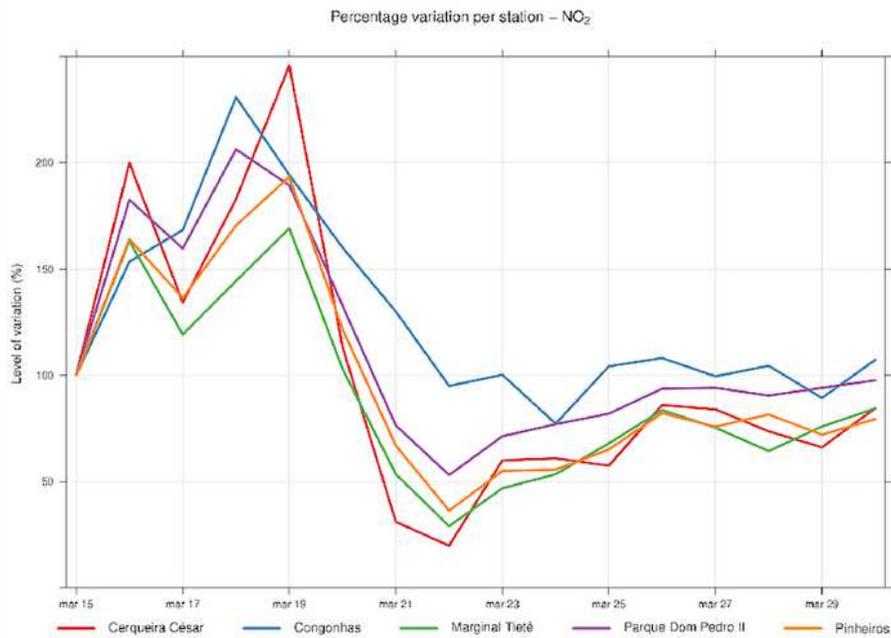

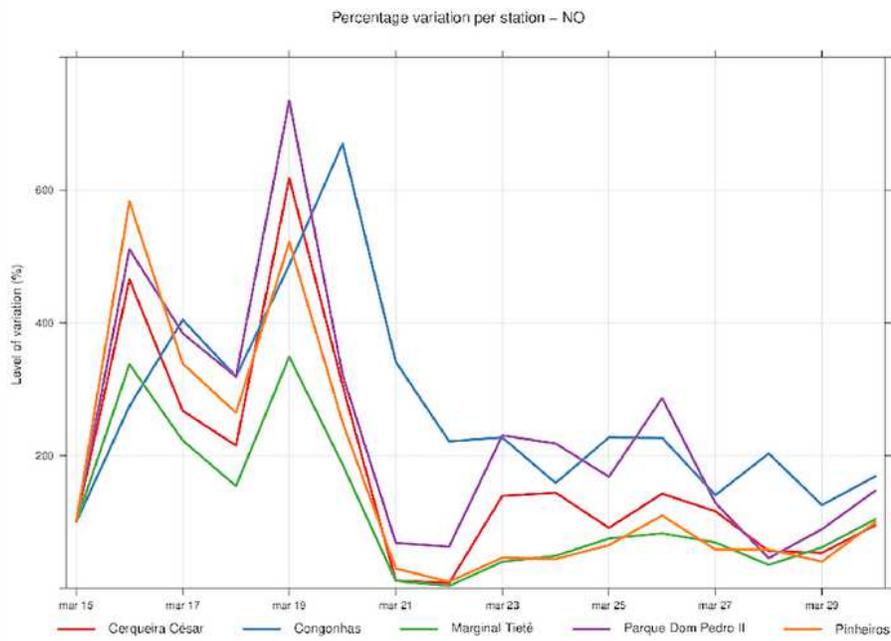

Geographic delimitation of the study area (São Paulo municipality) and location of the stations used in the study.

*Note: the dashed vertical lines indicate the intervention points determined via Pettitt's test.*

**Figure 2**

Time series of daily mean NO and NO<sub>2</sub> concentration, in units of  $\mu\text{g}\cdot\text{m}^{-3}$ , in the period between January 14th and April 12th, 2020.

**Figure 3**

Daily concentration percentage variation of NO (top) and NO<sub>2</sub> (bottom) in the period from March, 15th to March, 20th in 2020.
