Abstract

The anterior cingulate cortex (ACC) serves as a core region in social networks, and impairments in this area have been identified in autism spectrum disorders. Our prior research demonstrated that deficits in pyramidal neurons in ACC adversely impacted mouse social interaction. The preservation of functional output in the ACC by pyramidal neurons relies on the dynamic regulation by the different types of interneurons. However, the precise regulatory roles of distinct interneurons within the ACC in shaping social interaction have hitherto remained largely enigmatic. In this study, we elucidated the involvement of parvalbumin (PV) and somatostatin (SST) interneurons within the ACC in modulating social interaction behavior. Specifically, we ascertain that PV interneurons play a more prominent role in initiating sociability, whereas SST interneurons uniquely influence social preference. Notably, the downregulation of the autism high-risk gene *Kcnh7* is identified in both PV and SST interneurons within the *Shank3* knockout (KO) autistic mouse model. Further, the selective KO of *Kcnh7* in PV- or SST-positive neurons contributes to disruptions in sociability and social preference, respectively. The divergent modulation of social interaction by PV and SST interneurons in the ACC is attributed to the distinct input received by these neuronal subtypes. Our findings offer nuanced insights into the multifaceted roles of PV and SST neurons within the ACC in the context of social interaction, contributing to a comprehensive understanding of the neurobiological underpinnings of social behavior disorders in autism. The delineation of these mechanisms is imperative for advancing our comprehension of the etiological basis of autism, thereby paving the way for novel avenues of research aimed at addressing the heterogeneous phenotypes associated with social interaction dysfunction in cortical interneurons.

Social behavior encompasses a repertoire of critical adaptive skills for social species, including social interaction, social hierarchy, social fear, courtship behavior, and parenting behavior, all of which are important for population maintenance and offspring reproduction1. Of these, social interaction holds particular significance as it serves as a foundational precursor for other social behaviors by furnishing essential informational cues, encompassing sociability (identifying unfamiliar individuals) and preference (differentiating between unfamiliar and familiar individuals)[2-4]. Evolutionary conservation underscores the indispensability of social interaction in social life[5-8]. Investigating the neural underpinnings of social interaction using animal models not only enhances our comprehension of nervous system function and the construction of comprehensive brain functional networks but also furnishes valuable insights into the pathogenesis of related disorders, such as autism spectrum disorders (ASDs)[9, 10].

The anterior cingulate cortex (ACC), recognized for its regulatory role in cognition[11], attention[12], emotion[13, 14], decision-making[15], and somatic touch[16], is an area of particular interest concerning social interaction. ACC signaling alterations, as evidenced by imaging studies, have been associated with variations in social interests in both human and nonhuman primates[12, 17, 18]. Moreover, structural and functional alterations in the ACC correlate positively with deficits in social behavior observed in individuals with autism[19-21]. Despite its pivotal role, the ACC's contribution to social behavior has been comparatively underexplored. Our prior research establishes a significant causal link between social interaction deficits and dysfunction of pyramidal neurons in the ACC of mice with autistic-like behaviors, underscoring the critical role of these neurons in social interaction[22]. This suggests that these neurons play a critical role in social interaction.

Pyramidal neurons (PNs) are central to information transmission in the cortex, reliant upon precise regulation by surrounding GABAergic interneurons[23-25]. Parvalbumin (PV) and somatostatin (SST) interneurons, the two primary types directly innervating

83   pyramidal neurons in the ACC, modulate the dynamic role of pyramidal neurons and

84   maintain stable ACC functioning by receiving projections from other brain regions[24,

85   26-30]. However, the specific contributions of these interneurons to social interaction, as

86   key regulators of ACC function, remain a significant scientific question, particularly in

87   the context of social deficits associated with ASD. There is high heterogeneity in the

88   diverse behavioral abnormalities associated with the core symptoms of ASD[31, 32].

89   Sociability and social preference, which are essential components of social interaction,

90   are disrupted in both individuals with autism and autistic animal models. Given the fact

91   that distinct roles played by different types of interneurons in regulating the same

92   behavior[23, 24], we hypothesize that PV-positive and SST-positive neurons may

93   contribute differentially to the observed heterogeneity in ASD due to their distinct roles

94   in regulating behavior.

95   In the present study, we found that both PV and SST interneurons in the ACC are

96   implicated in social interaction, with PV interneurons displaying heightened sensitivity

97   to sociability and SST interneurons exhibiting more pronounced changes during social

98   preference. Notably, using *Shank3* mutant mice as a well-established ASD model, we

99   identified reduced expression of the *Kcnh7* gene, also a risk gene for ASD[33], through

100   single-cell RNA sequencing. Employing a Cre-dependent CRISPR-Cas9 viral approach

101   to individually knockout (KO) *Kcnh7* in PV or SST neurons in the ACC, we

102   demonstrated that PV interneuron *Kcnh7* KO led to impairments in social ability, while

103   SST neuron *Kcnh7* KO replicated deficits in social preference. The distinctive roles of

104   PV and SST interneurons are attributed to their divergent inputs. These findings provide

105   direct evidence for the distinct roles of PV and SST interneurons in the ACC in social

106   interaction and offer insights into the potential mechanisms contributing to the

107   heterogeneity of social dysfunction in individuals with ASD.

108   **Results**

109   **The activities of the PV and SST interneurons exhibited similar trends but**

110 **different detailed dynamics in the context of social interaction.**

111 Our previous work has indicated that pyramidal neurons in ACC are involved in

112 encoding signals associated with social interaction[22]. And also, distinct inhibitory

113 effects on pyramidal neurons in the ACC have been observed for PV and SST

114 interneurons[34]. Initially, we aim to investigate the potential involvement of the PV and

115 SST interneurons in modulating social interaction behavior. We selectively expressed

116 the calcium indicator GCaMP7s in PV or SST interneurons by injecting AAV2/9-

117 FLEX-GCaMP7s into the ACC of PV-Cre or SST-Cre transgenic mice (**Fig. 1A-C, and**

118 **Extended Data Fig. 1**). Subsequently, we quantitatively measured changes in calcium

119 signals of PV or SST interneurons associated with sociability in a home cage[35, 36],

120 employing four well-defined social interaction events: nose or genital sniffing,

121 following, and body contact (**Fig. 1D**). The results consistently revealed that social

122 interaction events suppressed the activity of PV or SST interneurons, with a more

123 substantial reduction in calcium signals observed in PV interneurons compared to SST

124 interneurons (**Fig. 1E, F**). Moving forward, we assessed the dynamics of PV and SST

125 interneuron activity during sociability and social preference utilizing a three-chamber

126 test[37]. The patterns of calcium signals for PV and SST interneurons during the initial

127 phase of the test (**Fig. 1G-I**) mirrored those observed during sociability in the home

128 cage (**Fig. 1E, F**). Notably, during the social preference phase, when test mice

129 approached unfamiliar mice (**Fig. 1J**), the changes in calcium signals of SST

130 interneurons were more pronounced than those of PV interneurons (**Fig. 1K, L**).

131 Furthermore, we conducted a comparative analysis of the dynamic fluctuations in

132 GCaMP levels between PV and SST interneurons at different stages of social interaction

133 behavior (**Fig. 1M-O**). In the sociability within the home cage, the area under the curve

134 (AUC) of the Ca^{2+} signal in PV interneurons surpassed that of SST interneurons (**Fig.**

135 **1M left**). While both PV and SST neurons exhibited a significant correlation between

136 AUC and the duration of social events, the correlation slope was notably greater in PV

137 neurons than in SST neurons (**Fig. 1M right**). A similar trend was observed in

138   sociability within the three-chamber apparatus (**Fig. 1N**). However, during social

139   preference within the three-chamber apparatus, the AUC and correlation slope of SST

140   neurons exceeded those of PV neurons (**Fig. 1O**). These findings collectively suggest

141   that the activity of PV and SST interneurons in the ACC is suppressed during social

142   interaction, with PV interneurons demonstrating heightened sensitivity to sociability

143   and SST interneurons exhibiting more pronounced changes during social preference.

144   **Apoptosis strategy intervention of PV and SST interneurons enhanced the**

145   **different phases of social interaction**

146   Next, we further investigated whether the inhibition of PV or SST interneurons

147   modulates different phases of social interaction using taCasp3[38]. This approach

148   selectively induced cell-autonomous apoptosis in two types of interneurons, and

149   subsequent examinations unveiled changes in social behavior (**Fig. 2A, B**). We first

150   confirmed that most of the PV and SST interneurons in the ACC were ablated through

151   quantification of the PVALB or SST positive cells and evaluation of the mRNA

152   expression levels of *Pvalb* or *Sst* (**Fig. 2C-E**). PV-Cre mice displayed more intense

153   social interaction in the three-chamber test and showed a heightened preference for

154   unfamiliar companions within their home cage after the taCasp3 virus intervention (**Fig.**

155   **2 F-H and K-L**). However, this intervention had negligible effect on socially preferred

156   behavior (**Fig. 2I, J**). Conversely, SST-Cre mice exhibited unaffected sociability (**Fig.**

157   **2M, N and R**) but showed a preference for interacting with a stranger object rather than

158   a familiar object in the social preference test (**Fig. 2O-Q**) due to the virus intervention.

159   These findings suggest that PV interneurons exert a more substantial influence on the

160   willingness to socialize, while SST interneurons wield a more potent modulation on

161   social preference.

162   **Activation of PV interneurons led to a more significant decrease in sociability**

163   **compared to the stimulation of SST interneurons in the home cage**

164   Next, we employed a Cre-dependent expression strategy of Channelrhodopsin-2 (ChR2)

165 to investigate the impact of exciting PV-positive and SST-positive interneurons on

166 social interaction behavior (**Fig. 3A**). The intent was to elicit firing in these interneurons

167 through a relatively high-frequency light stimulation, aligning with the inherent firing

168 properties of PV and SST interneurons[26, 39]. Our results substantiated that both PV and

169 SST interneurons expressed ChR2 with a probability of over 90% (**Extended Data Fig.**

170 **2A, B**). Moreover, we observed that PV interneurons expressing ChR2 exhibited

171 faithful generation of action potentials in response to 40 Hz photo stimulation

172 (**Extended Data Fig. 2C**) inducing c-Fos expression in PV-positive neurons (**Extended**

173 **Data Fig. 2E**). Similar observations were made for SST interneurons (**Extended Data**

174 **Fig. 2D, F**). In the home cage, the activation of PV interneurons resulted in a decrease

175 in social exploration behaviors with unfamiliar mice (**Fig. 3B**). Interestingly, social

176 interaction time did not fully recover in PV-ChR2 mice even following the cessation of

177 laser stimulation (**Fig. 3B**). Similarly, the activation of SST interneurons also

178 diminished social events and total social interaction time (**Fig. 3C**), with partial

179 recovery observed upon cessation of photo-stimulation (**Fig. 3C**). An intriguing

180 observation was the gradual decline in social interaction time between test mice and an

181 intruder after contact with the test mice's home cage. To explore the possibility that the

182 effect of ChR2 was influenced by the familiarity of the mice, we compared the

183 correlation of social interaction time differences between the first two stages (laser$_{ON}$-

184 laser$_{OFF}$) and the second two stages (laser$_{OFF}$-laser$_{ON}$). Results revealed that Cre-

185 negative mice exhibited a high correlation slope, suggesting a correlation between the

186 reduction in social interaction and time in this group (**Fig. 3D**). However, both PV and

187 SST neuron excitation led to significantly smaller correlation slope values, indicating a

188 correlation between social interaction impairment and photostimulation in these groups

189 (**Fig. 3D**).

190 Moreover, when comparing social interaction time during laser treatment among the

191 three groups, the Cre-negative group exhibited the highest social interaction time, while

192 the PV-Cre group demonstrated the shortest time (**Fig. 3E**). Additionally, the inhibition

193   index of ChR2 stimulation was compared between the PV-Cre and SST-Cre groups,

194   revealing a more pronounced decrease in social events upon the activation of PV

195   interneurons compared to the SST-Cre group (**Fig. 3F**).

196   Furthermore, when the intruder mouse was replaced with a toy mouse, both the PV-Cre

197   and SST-Cre groups exhibited no difference in social interaction, regardless of the laser

198   on or off status (**Fig. 3G**). Subsequent experiments exploring the effects of optogenetics

199   on social odor recognition in PV-Cre and SST-Cre mice indicated that the activation of

200   PV or SST interneurons did not alter the preference for the urine of a stranger mouse in

201   an open field (**Extended Data Fig. 3**).

202   **Activation of PV or SST interneurons inhibited the different stages of social**

203   **interaction in the three-chamber test**

204   Then we conducted experiments utilizing a three-chamber test, employing optogenetic

205   activation of PV or SST interneurons. In the initial sociability paradigm, PV-Cre mice

206   exhibited a tendency for interaction with the unfamiliar mouse in the absence of blue

207   light activation (**Fig. 3H, I left**). However, upon activation of PV interneurons by blue

208   light, the mice displayed a preference for the vacant zone (**Fig. 3H, I middle**). Post

209   cessation of laser stimulation, a tendency to return to the social zone was observed,

210   albeit without reaching statistical significance (**Fig. 3H, I right; Extended video 1**).

211   Furthermore, a significant disparity in social discrimination bias emerged between pre-

212   stimulus and during-stimulus periods (**Fig. 3J**). SST interneuron activation also

213   curtailed sociability, albeit with a distinct behavioral pattern from PV-Cre mice. Prior

214   to laser activation, SST-Cre mice exhibited a clear preference for the social zone (**Fig.**

215   **3N**, **O left**). However, during laser activation, SST-Cre mice spent comparable

216   durations in the social and empty zones (**Fig. 3N, O middle**), with a return to the social

217   zone upon cessation of SST interneuron excitation (**Fig. 3N, O right; Extended video**

218   **2**). Although discrimination scores exhibited a significant difference between laser off

219   and laser on conditions, values for SST-Cre mice approached zero, whereas those for

220   PV-Cre mice were negative (**Fig. 3J, P**).

221   In the social preference stage, PV-Cre mice initially favored the stranger zone, a
222   preference attenuated during laser activation (**Fig. 3K, L left and middle**). Upon
223   turning off the laser, mice spent similar durations in both the stranger zone and the
224   original zone (**Fig. 3L right**), with discrimination scores for the second stage showing
225   a significant difference between laser off and laser on conditions (**Fig. 3M**). For SST-
226   Cre mice, photo-stimulation prompted a shift from the stranger zone to the original zone.
227   Although statistical significance was not achieved, the mice still spent more time in the
228   original zone (**Fig. 3Q, R right**), mirroring the negative social discrimination score
229   observed in the first stage, akin to results obtained in PV-Cre mice (**Fig. 3M, S**).

230   Further comparisons of behavioral changes induced by optogenetic excitation of PV or
231   SST interneurons in the three-chamber test revealed that SST-Cre mice took longer to
232   discontinue engaging in social events during photo-stimulation compared to PV-Cre
233   mice in the first stage (**Fig. 3T**). Despite photo-stimulation reducing latency in both
234   groups compared to the condition without stimulation, the difference in discrimination
235   score between laser on and off conditions was more pronounced in PV-Cre mice than
236   SST-Cre mice (**Fig. 3U**), approaching statistical significance (**Fig. 3U**). In the second
237   stage, PV-Cre mice exhibited a preference for the center zone during blue light
238   activation, while SST-Cre mice showed no discernible preference (**Fig. 3W, X**). The
239   latency to cease the first social event in PV-Cre mice was lengthier than that in SST-
240   Cre mice during photo-stimulation (**Fig. 3V**). Furthermore, the difference in
241   discrimination scores exhibited an inverse pattern compared to the first stage, with SST
242   interneuron excitation producing a larger difference compared to PV interneurons (**Fig.
243   3Y**). Importantly, these optogenetic stimuli exerted no discernible influence on the
244   motor abilities of the mice (**Extended Data Fig. 4A, B**). In conclusion, the activation
245   of PV or SST interneurons exerts distinct effects on social interaction behavior, with
246   PV interneurons inhibiting sociability and SST interneurons reducing social preference.

Abnormal expression of *Kcnh7* in PV and SST-positive neurons is the cause of heterogeneous social interaction disorder in an autistic mice model

Given that the acute activation of PV or SST interneurons can inhibit distinct stages of the social interaction, our subsequent inquiry aimed to ascertain the presence of risk genes within the ASD model that may induce atypical PV or SST activity, thereby contributing to social impairments. *SHANK3* gene is identified as a high-risk gene for autism, and previous investigations have elucidated social interaction deficits in *Shank3* mutant mice[9, 40-49]. To achieve this objective, ACC tissues were meticulously dissected, and subsequent dissociation was followed by single-cell RNA sequencing (scRNA-seq) utilizing 10X Genomics technology. A total of 17,661 high-quality cells obtained from wild-type (WT) and *Shank3* KO male mice were subjected to comprehensive analysis, with clustering facilitated by Seurat[50]. Employing singleR[51] and manual analysis, seven distinct cell cluster types were identified (**Fig. 4A, B**), with representative marker genes, *Pvalb* and *Sst*, highlighted for simplicity (**Fig. 4C**). Further scrutiny involved an examination of gene expression differences between neurons exhibiting high *Pvalb* and *Sst* expression, revealing both upregulated and downregulated genes.

Of particular interest among the identified genes was *Kcnh7*, a member of the ether-a-go-go-related gene family, which displayed significant downregulation in both the *Pvalb* and *Sst* clusters (**Fig. 4D left, E left**). *Kcnh7* encodes ERG channels, voltage-gated potassium channels known for inward rectification during repolarization[52]. Notably, accumulating evidence associates *Kcnh7* with ASD, emphasizing its significance in neurobiology[33]. Quantitative analysis of *Kcnh7* expression was carried out through single-cell qRT-PCR with patch-clamp, revealing predominant expression in PV-positive and SST-positive neurons (**Fig. 4D right, E right**). Importantly, *Shank3* KO mice exhibited a significant decrease in *Kcnh7* expression in these neuron populations compared to WT mice, corroborating scRNA-seq findings (**Fig. 4F-G, K-L**). Moreover, PV-positive and SST-positive neurons in *Shank3* mutant mice displayed heightened excitability compared to WT mice (**Fig. 4H, I and M, N**). Administration

of E-4031, an ERG channel blocker, further heightened firing frequency in both PV- and SST-positive neurons (**Extended Data Fig. 5**). Additionally, both neuron types displayed decreased amplitudes of ERG channel currents in *Shank3* KO mice compared to WT mice (**Fig. 4J, O**). Based on these comprehensive findings, we posit that the aberrant expression of the Kv11.3 potassium channel, encoded by *Kcnh7*, in PV- and SST-positive neurons may contribute to heightened excitability, thereby influencing abnormal social interaction behavior observed in *Shank3* KO mice.

To investigate the proposed hypothesis, a Cre-dependent CRISPR–Cas9 viral methodology was employed. A virus expressing target RNAs, in combination with a Cre-dependent SpCas9 virus, was administered to PV-Cre and SST-Cre mice for the purpose of knocking out *Kcnh7* in the ACC (**Fig. 5A**). Immunofluorescent staining analysis validated the predominant presence of the gRNA-GFP virus in PV-positive neurons (**Fig. 5B, C**) and SST-positive neurons (**Fig. 5M, N**). Subsequent quantitative analysis demonstrated a significant reduction in KCNH7 levels within these neurons following the CRISPR–Cas9 viral intervention (**Fig. 5D, O**).

In order to evaluate the impact of *Kcnh7* on neuronal excitability, an examination of action potential components in PV-positive and SST-positive neurons was conducted (**Fig. 5E, F** and **P, Q**). The results indicated alterations in the half-width of the action potential and the first after hyperpolarization component induced by the *Kcnh7*-gRNA virus (**Fig. 5G, R**). Furthermore, PV and SST-positive neurons transduced with the *Kcnh7*-gRNA virus demonstrated a significant increase in the number of action potentials evoked by depolarizing current injections (**Fig. 5H, S**). Subsequent to these neurophysiological investigations, alterations in sociability and social preference were assessed following the CRISPR–Cas9 viral intervention. PV-Cre mice exhibited reduced sociability, spending less time in the social zone and more time in the center zone (**Fig. 5I, J left and right**), so the sociability had prominent differences before and after virus intervention (**Fig. 5K**). Notably, the Cas9 intervention group also displayed diminished sociability, evidenced by similar activity in both the social zone and empty

303 zone (**Fig. 5L**). In the subsequent phase of the three-chamber test, PV-Cre mice

304 demonstrated decreased time spent in both the stranger social zone and the original

305 social zone (**Extended Data Fig. 6A, B**), with no discernible change in the

306 discrimination score (**Extended Data Fig. 6C**).

307 The impact of *Kcnh7* knockout on the social preference of SST-Cre mice was then

308 investigated through three-chamber tests. Post-virus injection, SST-Cre mice spent less

309 time in stranger social zone and more time in original zone (**Fig. 5T, U left and middle**).

310 Further analysis revealed a more pronounced decrease in the stranger zone compared

311 to the original zone (**Fig. 5V**). Additionally, SST-Cre mice exhibited abnormal social

312 preference capacity, spending significantly more time in the original social zone (**Fig.**

313 **5W**). Initial stages of the three-chamber test also indicated reduced sociability in SST-

314 Cre mice, characterized by decreased time spent in the social zone and increased time

315 in the empty zone (**Extended Data Fig. 6D-F**). These findings suggest distinct roles

316 for PV-positive and SST-positive GABAergic interneurons in social interaction related

317 disorders and emphasize the potential significance of *Kcnh7* in modulating the function

318 of these neurons within the ACC, thereby influencing social behavior.

319 **Specific projections contribute to the differential inhibition on the social**

320 **interaction behavior of PV and SST interneurons in the ACC**

321 Although the activation of PV or SST neurons can inhibit different phases of social

322 behavior, this regulation is mediated through the influence of pyramidal neurons. Our

323 observations revealed variations in the short-term plasticity of inhibitory synaptic

324 transmission from these interneurons to pyramidal neurons, as well as differences in

325 their firing patterns (**Extended Data Fig. 7**). Additionally, the distinct impact of these

326 interneurons may be linked to the differences in the projections received by each type

327 of interneuron. Subsequently, we embarked on an investigation aimed at elucidating a

328 potential circuit mechanism underlying the observed discrepancy in social interaction

329 ability between PV and SST interneurons. Our approach involved employing whole-

330   brain retrograde tracing using rabies viral vectors (RVs) that were modified with

331   engineered rabies glycoprotein (RG) deletion[53]. PV-Cre or SST-Cre mice were injected

332   with an adeno-associated virus (AAV) helper vector and AAV-double-floxed inverted

333   open reading frame (DIO)-RVG, enabling the visualization of starter neurons and

334   providing essential components for retrograde tracing. Subsequently, RV-EnvA-ΔG-

335   dsRed was injected after a three-week interval to label neurons expressing the required

336   components (**Fig. 6A**).

337   The results exhibited that the starter neurons were predominantly situated in the ACC,

338   with a lesser presence in the adjacent PFC region (**Fig. 6B, C and E**). Subsequent

339   analysis of the number of cells per unit area upstream was conducted by referencing

340   The Mouse Brain in Stereotaxic Coordinates (second edition), revealing that both PV

341   and SST interneurons shared comparable upstream afferents. Particularly, the lateral

342   posterior thalamic nucleus (LPMR) exhibited heightened expression upstream of PV-

343   positive neurons, while the ventral hippocampus (vHPC) displayed elevated expression

344   upstream of SST neurons (**Fig. 6D, F**).

345   To delve into the synaptic connectivity type between LPMR and PV interneurons in the

346   ACC, optogenetics and whole-cell patch-clamping techniques were employed in brain

347   slices. The results exhibited that LPMR formed an excitatory monosynaptic projection

348   to PV interneurons (**Extended Data Fig. 8A, B**). Similarly, the projection from the

349   ventral hippocampus (vHPC) to SST interneurons in the ACC demonstrated the same

350   type of connectivity (**Extended Data Fig. 8A, C**). To further corroborate these

351   projections *in vivo*, GCaMP7 expression on PV or SST interneurons in the ACC was

352   achieved using a Cre-dependent strategy, and ChR2 was expressed upstream of the

353   ACC using the AAV2-retro serotype (**Extended Data Fig. 8D, G**). An optic fiber was

354   implanted into the LPMR or vHPC for upstream excitation, while another fiber was

355   inserted into the ACC to record the GCaMP7 signaling of PV or SST interneurons

356   receiving the projection from upstream. Activation of LPMR or vHPC through 40 Hz

357   473 nm photo stimulation significantly elevated the calcium signaling of PV or SST

358 interneurons in the ACC (**Extended Data Fig. 8F, I**), thereby affirming the existence

359 of these two pathways from both morphological and functional perspectives.

360 Subsequently, we sought to elucidate whether the delineated pathways were implicated

361 in the distinct modulation of social behavior by PV and SST interneurons within the

362 ACC. AAV1-Flp-EGFP[54] was injected into the LPMR of PV-Cre mice to achieve

363 transmonosynaptic anterograde expression of Flp in the postsynaptic neurons of LPMR,

364 including those within the ACC. Concurrently, AAV-hSyn-Con-Fon-ChR2-mCherry[55]

365 was injected into the ACC to facilitate the expression of ChR2 in PV interneurons

366 innervated by LPMR (**Fig. 7A-C**).

367 Subsequent social interaction tests in the home cage and three-chamber were conducted,

368 during which photoactivation was temporally coordinated as in previous experiments

369 (**Fig. 3**). The outcomes revealed that the activation of PV interneurons in the LPMR-

370 ACC pathway led to a reduction in social interaction time in the home cage (**Fig. 7D,**

371 **E**) and an augmented preference for the empty zone in the three-chamber setup (**Fig.**

372 **7H-J**). And mCherry-control group had no significant effect on social behavior in home

373 cage test (**Fig. 7F, G**). Importantly, in the second phase of the three-chamber test, this

374 pathway did not significantly alter normal social appetitive behavior (**Extended Data**

375 **Fig. 9A, B**). Additionally, we identified projections from the ventral hippocampus

376 (vHPC) to PV-positive interneurons in the ACC. However, selectively exciting the

377 vHPC to PV-positive interneurons projection did not markedly influence preference

378 behavior in the second part of the three-chamber test (**Fig. 7K**).

379 Employing a similar strategy, we activated the projection from the vHPC to SST-

380 positive interneurons in the ACC and assessed its impact on social preference behavior

381 (**Fig. 7L-N**). Results indicated that the specific regulation of the vHPC to SST

382 interneurons influenced social preference behavior (**Fig. 7O-Q**) in SST-Cre mice during

383 the three-chamber test. In the mCherry-control group, the excitation of SST

384 interneurons in this projection did not result in significant changes in social preference

385 compared to the ChR2 group (**Fig. 7R, S**). Furthermore, the stimulation did not

386 significantly alter the active social exploration behavior of the SST-Cre mice in the first

387 phase of the three-chamber test (**Extended Data Fig. 9C**, **D**). Collectively, these

388 findings affirm our hypothesis that the targeted regulation of these two circuits can

389 potentially serve as a strategy to address the heterogeneity of social interaction

390 disorders.

391 **Discussion**

392 Projection neurons are functional executors across diverse brain regions, leveraging

393 their axons to convey essential instructions to downstream targets. However, the

394 precision of projection neuron performance is not solely reliant on intrinsic factors. It

395 is significantly influenced by local interneurons, contributing to diverse regulatory

396 mechanisms, including feedback and feedforward processes[56, 57]. Previous extensive

397 research have delved into their functions in crucial cognitive domains such as working

398 memory[58], flexibility[59], and various other facets[34, 60-62]. This underscores the essential

399 need to comprehend the specific contributions of interneurons within a given brain

400 region. In this study, our attention focused on two primary interneuron subtypes within

401 the ACC: PV and SST interneurons. We found that PV and SST interneurons in the

402 ACC exert distinct effects on social interaction behavior. Specifically, PV interneurons

403 exhibit heightened sensitivity to sociability, while SST interneurons show more

404 pronounced changes during social preference. In a *Shank3* autistic model, the *Kcnh7*

405 gene, a known risk gene for ASD, was found to be reduced in the PV and SST

406 interneurons of the ACC. Deletion of *Kcnh7* specifically in PV or SST interneurons in

407 the ACC contributes to the variability of social interaction disorders. Additionally, the

408 specific pathways from LPMR to PV and vHPC to SST in the ACC represent a potential

409 mechanism for generating the differential roles of these interneurons. Our findings

410 suggest that both types of interneurons in the ACC are involved in the regulation of

411 social interaction, exhibiting differentiation in their regulatory functions. PV

412 interneurons are implicated in regulating social abilities, while SST interneurons are

413   more involved in regulating social preferences. This finding aligns with observations

414   of PV and SST interneurons in other behavioral paradigms, confirming the distinct roles

415   of different interneuron types in regulating projection neurons[58-61].

416   Given the distinct regulatory roles of PV and SST interneurons in modulating projection

417   neurons and their potential implications for the functioning of the relevant brain area,

418   it is imperative to delve into the underlying mechanisms. This exploration is not only

419   crucial for understanding social behavior but also holds the promise of providing

420   insights into associated disorders, such as ASD. Recent studies have demonstrated that

421   these two neuron types may exhibit varying sensitivities to the same stimuli in

422   hippocampus[63] and cortex[64]. Notably, the KO of *Mecp2*, a high-risk gene for autism, in

423   either PV or SST neurons in the hypothalamus yields significantly different phenotypes

424   in mice, mirroring the distinct manifestations of Rett syndrome[65]. Intriguingly, our

425   present work found that selectively knocking out *Kcnh7*, a susceptibility gene for ASD

426   [33, 66], in PV or SST neurons can impair social ability or social preference, respectively.

427   The downregulation of *Kcnh7* gene expression was found in PV and SST neurons in

428   *Shank3* KO mice, a model of autism primarily associated with excitatory synaptic

429   dysfunction in projection neurons. As KCNH7 serves as an inward rectifying potassium

430   channel crucial for regulating neuronal excitability[52, 67], the downregulation of its

431   expression could result in heightened excitability in PV and SST neurons (**Fig. 5**). This

432   augmented excitability in PV and SST neurons has been associated with impaired social

433   interaction, as corroborated by our optogenetic experiments (**Fig. 3**). These collective

434   findings strongly indicate that the phenotypic abnormalities observed in *Shank3* KO

435   mice are not solely ascribed to projection neuron abnormalities but likely involve

436   interneurons. Indeed, our observations reveal that sensory hypersensitivity in this model

437   is associated with interneuron abnormalities[68]. These results underscore that PV and

438   SST neurons, despite exposure to the same stimuli, elicit distinct responses. The

439   differential regulation of projection neurons by these interneurons may thus contribute

440   to variations in social behavior. Moreover, this insight into the intricate interplay

441 between molecular (such as *Shank3* and *Kcnh7*), cellular (PV neurons, SST neurons,

442 and projection neurons), and behavioral phenomena enhances our understanding of the

443 neurobiological underpinnings of social dysfunction and related disorders.

444 While the involvement of PV or SST interneurons is integral to the regulation of social

445 interaction, the synaptic inputs into these interneurons play a pivotal role in their

446 operations. Notably, glutamatergic axons originating from projection neurons in the

447 mediodorsal thalamic nucleus selectively target PV neurons in ACC, initiating

448 feedforward inhibition of pyramidal neurons in layer 3 of the ACC and thereby

449 impacting cognitive flexibility[27]. Additionally, axons emanating from hippocampal

450 neurons that target SST neurons in the medial prefrontal cortex (mPFC) have been

451 shown to influence the accuracy of working memory[69]. These insights underscore the

452 significance of projections from diverse brain regions to PV and SST neurons as

453 potential mechanisms governing the distinctive roles of these interneuron types. Our

454 research further reveals that, despite receiving similar inputs, PV and SST neurons

455 exhibit differentiation in input, potentially contributing to the distinct regulation of

456 social interaction functions. Specifically, our observations indicate that LPMR

457 projecting to PV neurons in the ACC are involved in regulating social ability, whereas

458 vHPC projecting to SST neurons in the ACC play a key role in regulating social

459 preference. The LPMR, a crucial region implicated in the attention network[70],

460 establishes connections with the visual cortex, parietal cortex, and ACC[71-73]. Anomalies

461 in connectivity between the LPMR and cortex, coupled with a thinner parietal cortex

462 and atypical visual processing observed in individuals with ASD[74-76], suggest that

463 attention networks involving the LPMR play a crucial role in processing social relation

464 information and related disorders such as ASD. Concerning the HPC, it has been

465 traditionally implicated in social preference[77, 78]. However, recent research proposes

466 that the vHPC modulates social memory through PV neurons in the mPFC[79].

467 Intriguingly, a substantial body of evidence highlights contrasting roles of the ACC and

468 mPFC in social behavior in mice[22, 23, 80]. This observation implies that the ACC and

469   mPFC may possess distinct functional characteristics contributing to social behavior in

470   murine models. This nuanced understanding of the interconnected brain regions and

471   their differential roles enhances our grasp of the neurobiological underpinnings of

472   social behavior, providing valuable insights into potential therapeutic avenues for

473   disorders associated with social dysfunction.

474   Moreover, it is imperative to acknowledge the involvement of brain regions beyond the

475   ACC in the intricate modulation of social behavior. Recent investigations highlight the

476   participation of SST neurons in the mPFC in mediating disinhibition, functioning as a

477   pivotal circuit mechanism to regulate social fear behavior[23]. Additionally, Zhang et al.

478   reported the formation of a disinhibitory microcircuit in the dorsomedial prefrontal

479   cortex involving VIP, PV, and pyramidal neurons, governing social competition in mice

480   [24]. Numerous comprehensive reviews have delved into the neural circuitry

481   underpinning social behavior[1, 81-83]. Furthermore, the cortex houses a myriad of

482   interneuron types beyond the aforementioned PV and SST interneurons. Our recent

483   discovery underscores the role of cholecystokinin interneurons in the ACC, revealing

484   their contribution to social isolation-induced social impairments. This finding suggests

485   a broader involvement of various interneuron types in social interaction[84]. A

486   comprehensive investigation utilizing electrophysiological, morphological, and

487   transcriptomic analyses has identified 28 distinct classifications of interneurons within

488   the visual cortex of mice[85]. However, fully understanding the roles played by these

489   diverse subtypes of interneurons remains a challenging endeavor. Further research is

490   imperative to develop reliable analytical techniques capable of elucidating the intricate

491   relationship between interneuron subtypes characterized by molecular markers and

492   those characterized by their functional activities. This pursuit is essential for unraveling

493   the complex network of interactions that govern social behavior at the neural level.

494   To the best of our knowledge, the present research provides strong evidence that PV

495   and SST interneurons in the ACC play a distinct role in social interaction. Specifically,

496   our findings highlight that PV-positive interneurons predominantly regulate sociability,

while SST-positive interneurons play a more significant role in shaping social preference behaviors. The nuanced roles exhibited by these interneuron types during social interaction within the ACC likely contribute to the diverse manifestations of social interaction deficits. This insight opens new avenues for understanding and potentially addressing related disorders, particularly autism, shedding light on novel therapeutic approaches grounded in the specific functions of PV and SST interneurons in the intricate network governing social behaviors.

Figures and Figure legends
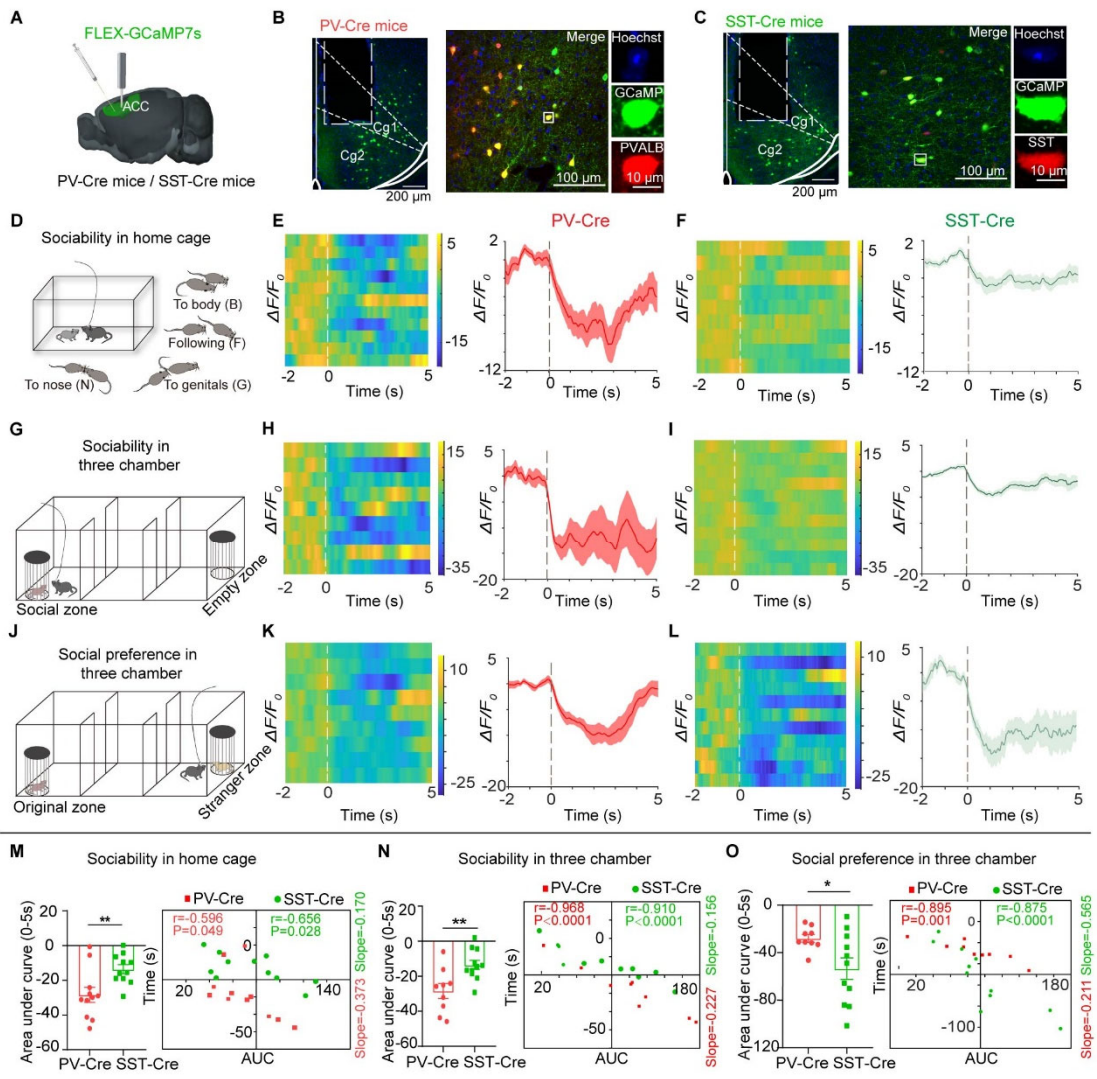

Fig. 1 PV and SST interneurons show varied activities dynamics during social interaction behavior. A. Schematic of FLEX-GCaMP7s injection into the ACC of PV-Cre mice and SST-Cre mice. **B.** Representative image showing the placement of an optic fiber for fiber photometry in the ACC of a PV-Cre mouse injected with GCaMP7s (left) and GCaMP7s expression in the ACC (right). **C.** Representative micrograph showing the placement of an optic fiber for fiber photometry in the ACC of an SST-Cre mouse injected with GCaMP7s (left) and GCaMP7s expression in the ACC (right). **D.** Schematic of social recognition behavior in the home cage. **E.** Ca^{2+} signals associated with social recognition in the home cage. Left panel, the heatmap illustration of Ca^{2+} signals aligned to the onset of each social recognition behavior (to nose, to body,

following or to genitals). Each row represents one mouse. The color scale on the right indicates $\triangle F/F_0$. Right panel, the peri-event plot of the average Ca^{2+} transients. Thick lines indicate the mean, and shaded areas indicate the SEM. Dotted line indicates the moment of contact with the social object. **F.** The same as **E** but for SST-Cre mice. **G.** Schematic of active social behavior in the three-chamber test. **H-I.** The same as **E** but for PV-Cre mice (**H**) and SST-Cre mice (**I**) in three-chamber test for active social behavior. Dotted line indicates the moment of contact with the cage of the social object. **J.** Schematic of social preference behavior in the three-chamber test. **K-L.** The same as **E** and **F** but for PV-Cre mice (**K**) and SST-Cre mice (**L**) in three-chamber for social preference behavior. Dotted line indicates the moment of contact with the cage of the stranger social object. **M.** Area under curve in home cage test (left) and the correlation index between social duration and neuronal activities in PV-Cre and SST-Cre groups (right). **N.** Area under curve in first phase of three-chamber test (left) and the correlation index between social duration and neuronal activities in PV-Cre and SST-Cre groups (right). **O.** Area under curve in second phase of three-chamber test (left) and the slope function compares the change in PV-Cre and SST-Cre groups (right). Data are presented as the mean ± s.e.m. *$p<0.05$, **$p<0.01$.

753
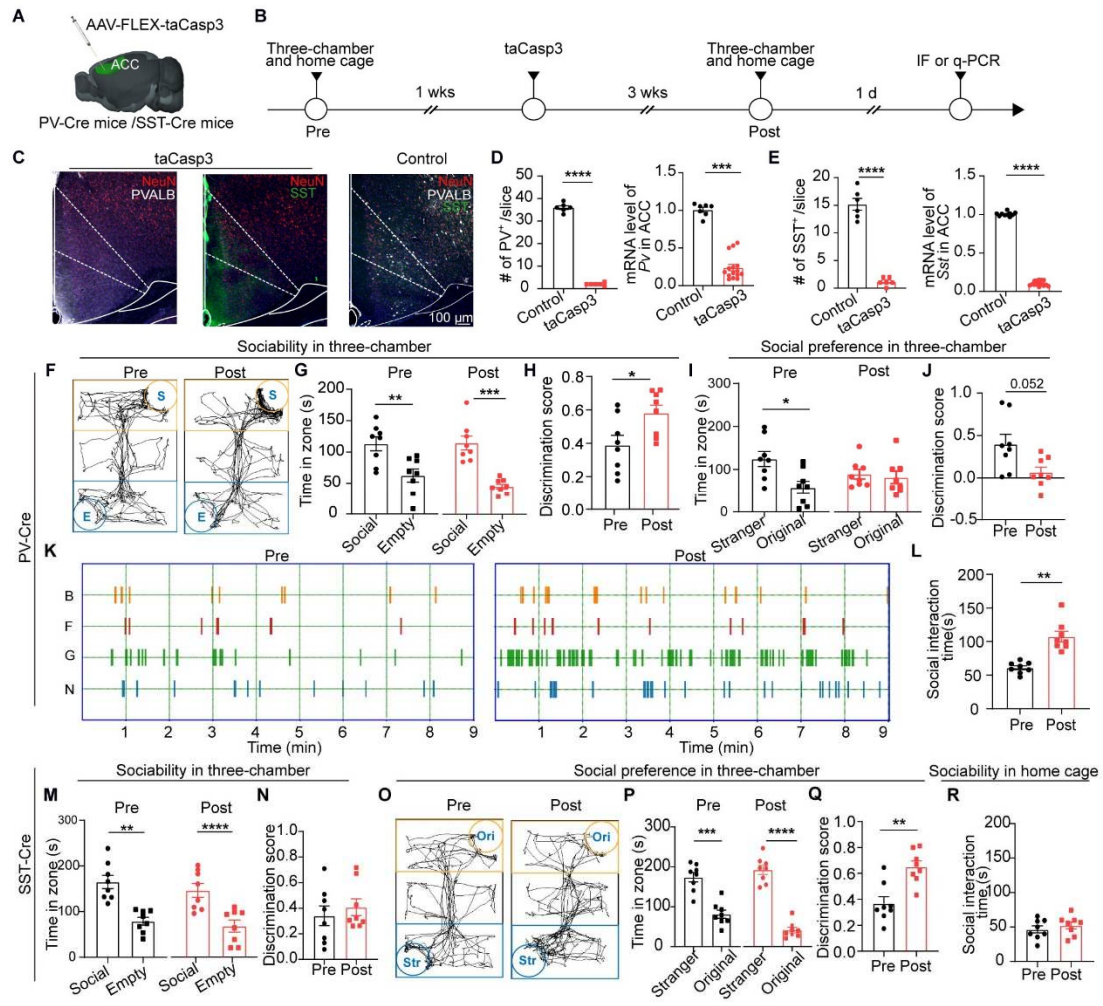

Fig. 2 The apoptosis strategy intervention of PV and SST interneurons improved various stages of social interaction. A. Schematic of FLEX-taCasp3 injection into the ACC of PV-Cre mice and SST-Cre mice. **B.** Timeline of this test. **C.** The results of IF between the intervention group and the control group. **D.** Quantification of PV$^+$ cells between the intervention group and the control group (left) and quantification of mRNA levels of *Pvalb* between the intervention group and the control group (right). **E.** The same of **C** and **D** but of SST-Cre mice. **F.** Traces of PV-Cre mice before (left) and after (right) virus intervention in the sociability test. **G-H.** Quantification of time spent (**G**) and discrimination score (**H**) showing that PV-Cre mice spent more time in the social zone after intervention (discrimination score: calculated by time spent in social zone minus time spent in empty zone/total time spent in both of these zones). **I-J.** Quantification of time spent (**I**) and discrimination score (**J**) in second phase in three-

766   chamber test showing that decreased social interest with stranger after virus

767   intervention (discrimination score: calculated by time spent in stranger zone minus time

768   spent in original zone/total time spent in both of these zones). **K.** Different social

769   interaction types in home cages increased after virus intervention of PV-Cre mice. **L.**

770   Quantification of time spent showing that PV-Cre mice spent more time with social

771   objects after virus intervention in home cage. **M-N.** Quantification of time spent

772   showing that SST-Cre mice spent more time in the social zone before and after virus

773   intervention (**M**) and discrimination score had no change of SST-Cre mice in three-

774   chamber test of sociability stage (**N**). **O.** Traces of SST-Cre mice before (left) and after

775   (right) virus intervention in the social preference test. **P-Q.** Quantification of time spent

776   (**P**) and discrimination score (**Q**) in second phase in three-chamber test showing that

777   SST-Cre mice spent more time in the stranger zone after virus intervention in three-

778   chamber. **R.** Discrimination score showing that social interaction had no obviously

779   change of SST-Cre mice spent with social object in home cage before and after virus

780   intervention. Data are presented as the mean ± s.e.m. *$p<0.05$, **$p<0.01$, ***$p<0.001$,

781   ****$p<0.0001$.

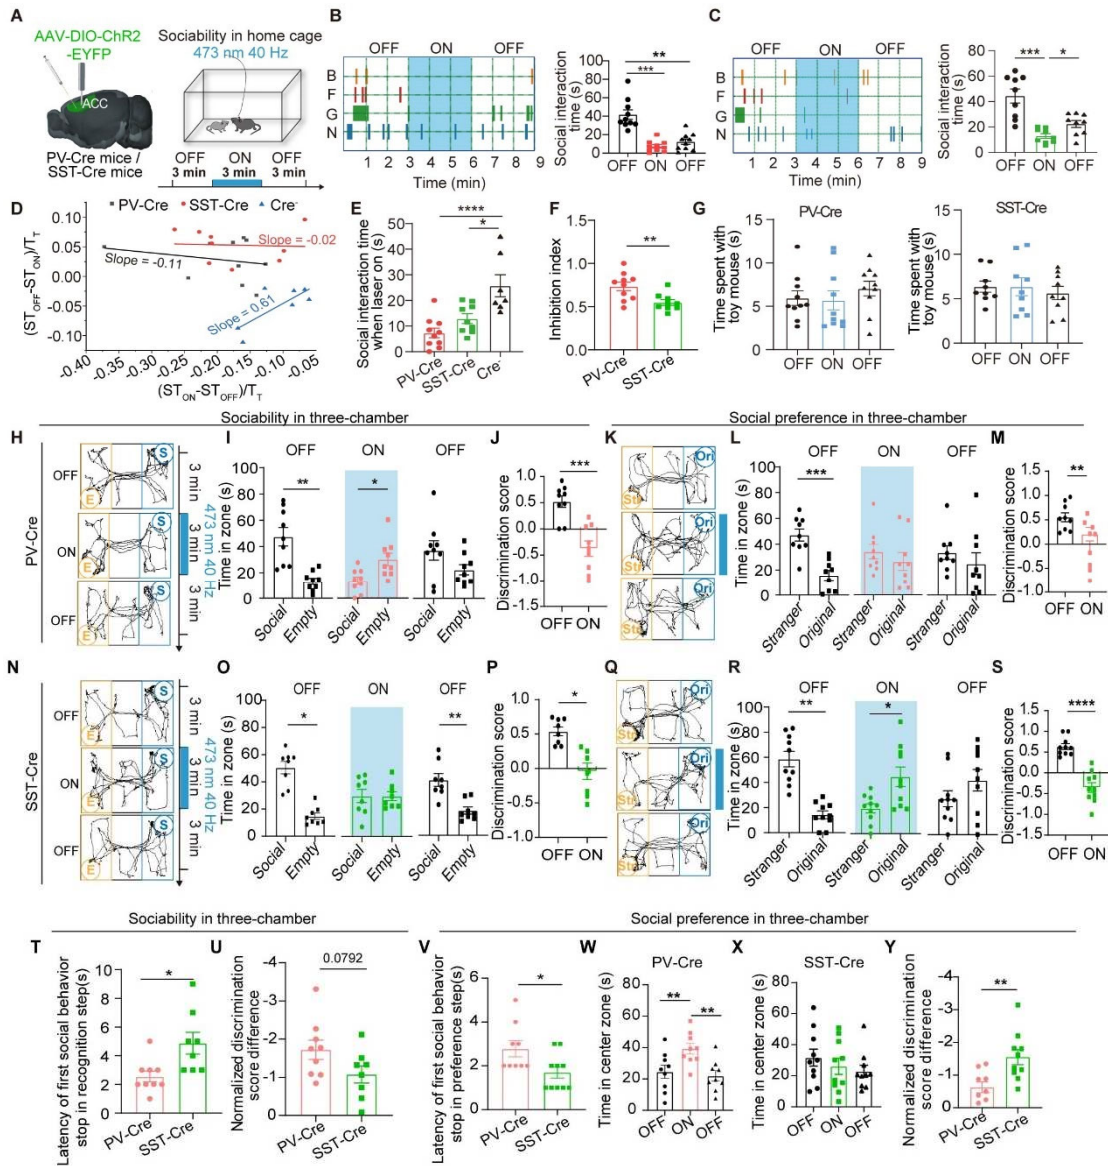

Fig. 3 Optogenetic activation of PV or SST interneurons suppressed different phases of social interactions. A. Schematic of DIO-ChR2 injection into the ACC of PV-Cre mice and SST-Cre mice (left) and diagram of the home cage test and laser delivery strategy (right). **B.** Change process of different social interaction types in the home cage when stimulus of PV-Cre mice (left) and statistical analysis of behavioral changes in PV-Cre mice (right). **C.** The same as **B** but stimulus of SST-Cre mice. **D.** Comparison of slope coefficient values in the PV-Cre group, SST-Cre group and EYFP control group. **E.** Summary data of time of social interaction when laser on. **F.** Inhibition index between PV-Cre mice and SST-Cre mice showing that the inhibition of PV-Cre

795 mice was more notable than that of SST-Cre mice (inhibition index: calculated by time

796 spent with social object when laser off minus when laser on/total time spent with social

797 object when laser off and on). **G.** Summary data of time spent with toy of PV-Cre mice

798 group (left) and SST-Cre mice group (right). **H.** Traces of PV-Cre mice in the active

799 social recognition test. **I.** Summary data of the active social recognition test showing

800 that PV-Cre mice spent more time in the social zone (left panel) before laser on, spent

801 more time in the empty zone when laser on (middle panel) and preferred the social zone

802 after laser on (right panel). **J.** Discrimination score (calculated by time spent in the

803 social zone minus time in the empty zone /total time spent in the social zone and in the

804 empty zone) of PV-Cre mice in active social recognition. **K.** Traces of PV-Cre mice in

805 the social preference test. **L.** Summary data of the social preference test showing that

806 PV-Cre mice spent more time in the stranger zone (left panel) before laser on, no

807 significant difference between the stranger zone and the original zone when laser on

808 (middle panel) and after laser on (right panel). **M.** Discrimination score of PV-Cre mice

809 in social preference test. **N.** Traces of SST-Cre mice in the active social recognition test.

810 **O.** Summary data of the active social recognition test showing that SST-Cre mice spent

811 more time in the social zone (left panel) before laser on, no time spending difference in

812 social zone neither in empty zone when laser on (middle panel) and preferred the social

813 zone after laser on (right panel). **P.** Discrimination score of SST-Cre mice in active

814 social recognition. **Q.** Traces of SST-Cre mice in the social preference test. **R.** Summary

815 data of the social preference test showing that SST-Cre mice spent more time in the

816 stranger zone (left panel) before laser on, spent more time in the original zone when

817 laser on (middle panel) and showed no significant difference after laser on (right panel).

818 **S.** Discrimination score of SST-Cre mice in social preference test. **T.** Summary data of

819 the delay time when the first social behavior stop of PV-Cre group and SST-Cre group

820 in active social behavior in three-chamber. **U.** Comparison of discrimination scores

821 between PV-Cre and SST-Cre mice in the active social test. **V.** Summary data of the

822 delay time when the first social behavior stop of PV-Cre group and SST-Cre group in

823   stranger zone in three-chamber. **W-X.** Summary data of time spent in the center zone

824   by PV-Cre mice (**W**) and SST-Cre mice (**X**) in the preference test. **Y.** Comparison of

825   discrimination scores between PV-Cre and SST-Cre mice in social preference test. Data

826   are presented as the mean ± s.e.m. *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$.

856

857
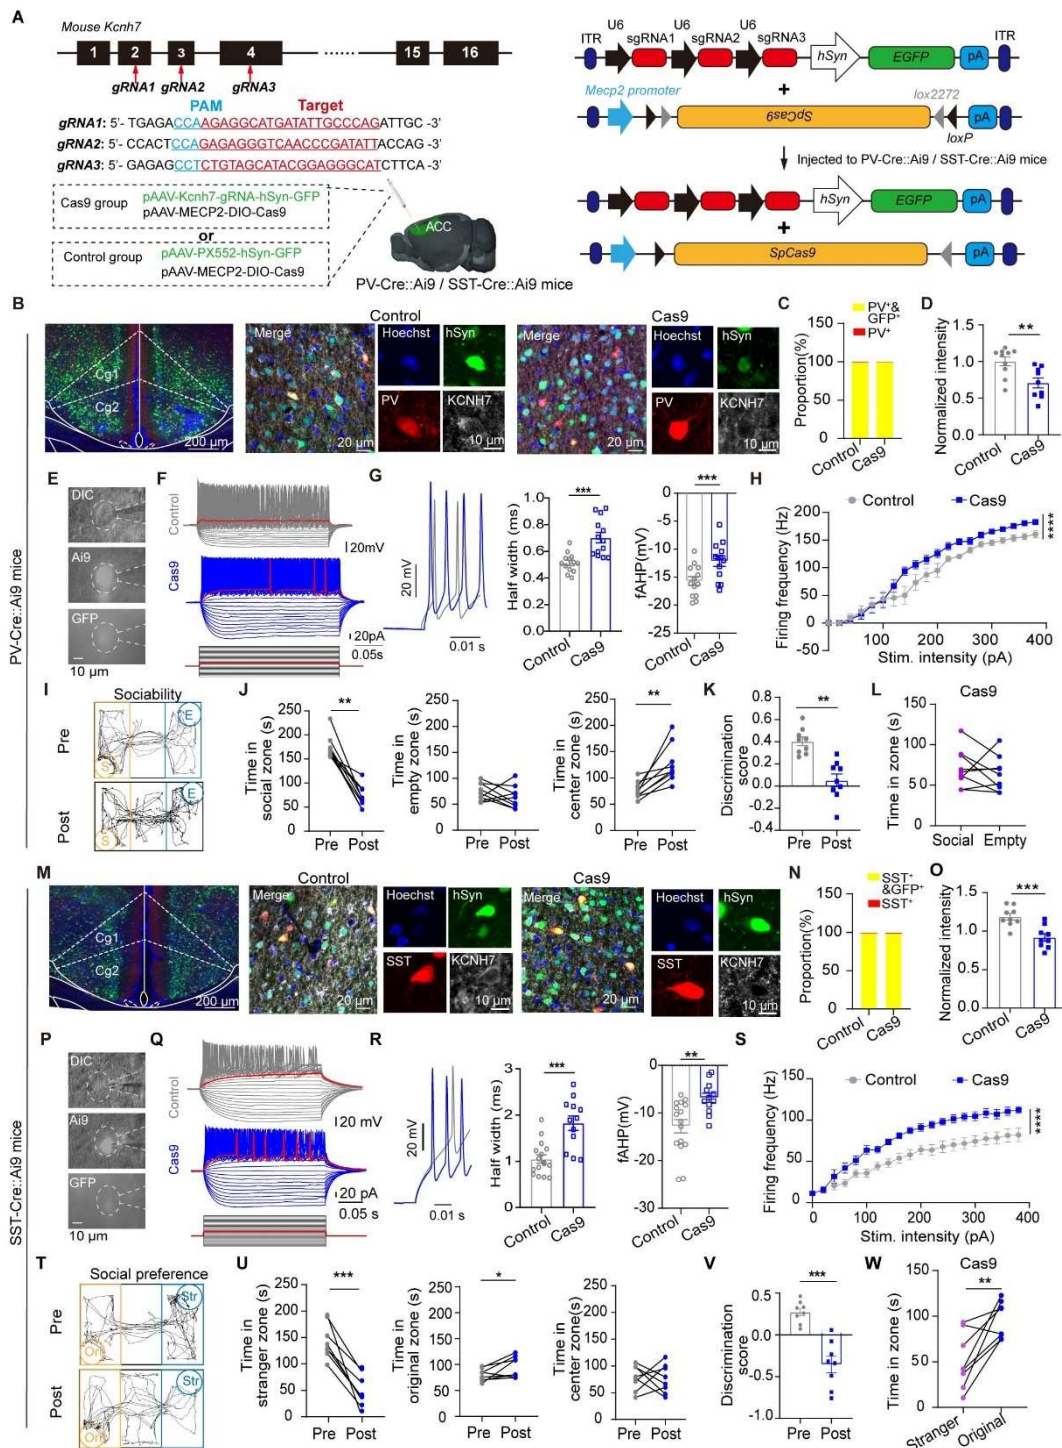

Fig. 5 Using CRISPR-Cas9 technology, specific KO *Kcnh7* in PV and SST neurons resulted in heightened neuronal excitability and differential impairment in social interaction. A. CRISPR-Cas9 viral approach to knockout *Kcnh7* in PV+ neurons and SST+ neurons. **B.** For PV-Cre mice, images showing AAV-sgRNA-hSyn-GFP expression (left) and KCNH7 expression between the control group (middle) and knockout group (right). **C-D.** More than 99% of PV+ neurons were GFP+ (**C**), and

relative KCNH7 protein expression significantly decreased after the CRISPR-Cas9 approach *in vivo* (**D**). **E-G.** *Ex vivo* recording from the control group and KO group (**E**) showing the neuronal excitability (**F**), action potential half width (**G** left, middle) and first after hyperpolarization (fAHP) (**G** right). **H.** Input-output diagram of spike frequency of PV-Cre neurons between control virus and Cas9 virus. **I-L.** Compared with social behavior prior to viral injection, PV-Cre mice spent less time in the social zone and more time in the center zone (**I-J**) and showed reduced sociability (**K-L**). **M.** For SST-Cre mice, images showing AAV-sgRNA-hSyn-GFP expression (left) and KCNH7 expression between the control group (middle) and knockout group (right). **N-O.** More than 99% of SST^+ neurons were GFP^+ (**N**), and relative KCNH7 protein expression significantly decreased after the CRISPR-Cas9 approach *in vivo* (**O**). **P-R.** *Ex vivo* recording from the control group and knockout group (**P**) showing the neuronal excitability (**Q**), action potential half width (**R** left, middle) and fAHP (**R** right). **S.** Input-output diagram of spike frequency of SST-Cre neurons between control virus and Cas9 virus. **T-W.** Compared with social preference behavior prior to viral injection, SST-Cre mice spent less time in the stranger zone and more time in the original zone (**T-U**) and showed reduced social preference (**V-W**). Data are presented as the mean ± s.e.m. *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$.

883
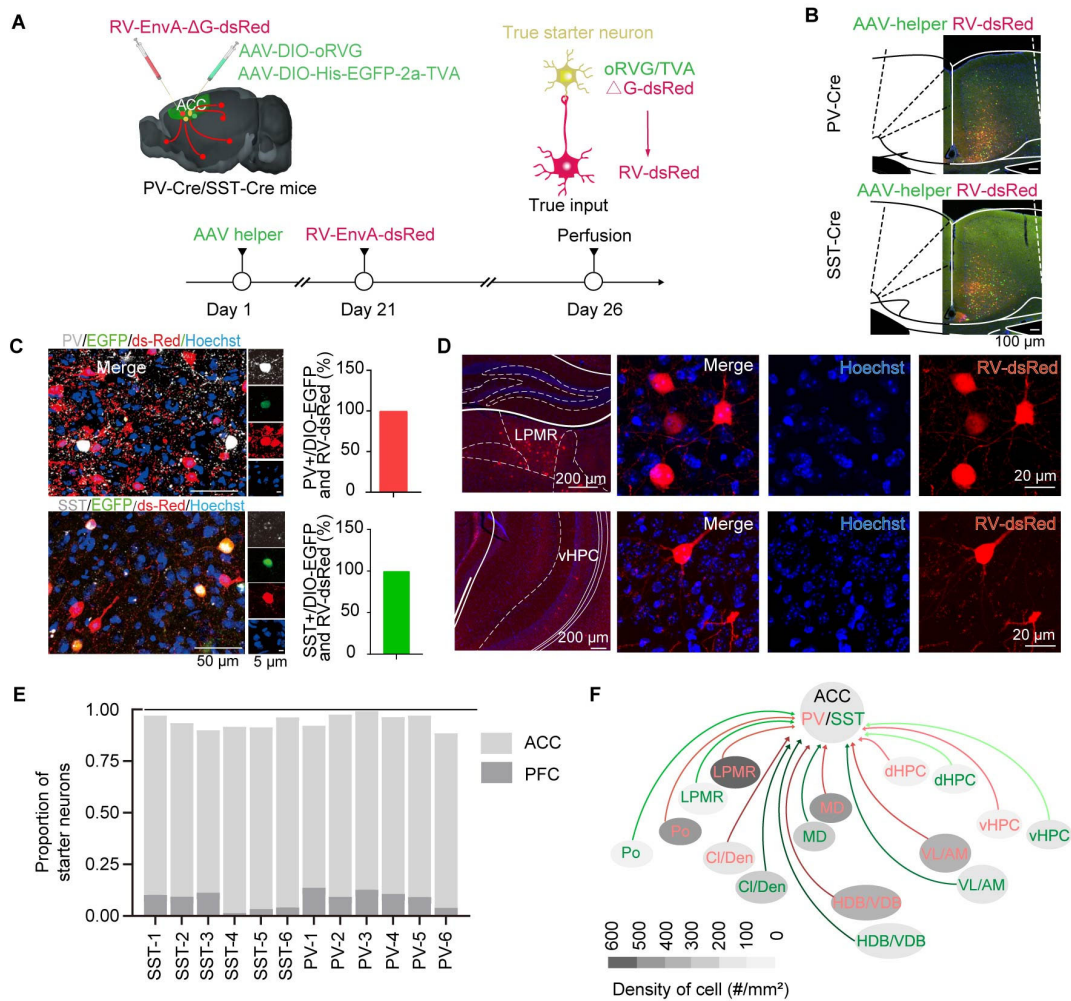

Fig. 6 Retrograde monosynaptic tracing revealed that LPMR and vHPC may serve

as potential distinct inputs that innervate the PV and SST neurons within the ACC.

A. The AAV helper virus was injected into the ACC of PV- and SST-Cre animals. Three

weeks later, RV-dsRed was targeted to the same location. Bicistronic expression of TVA

and oRVG from a single AAV vector optimizes the generation of true starter neurons,

that is, neurons able to give rise to retrograde transsynaptic labeling of monosynaptic

input neurons. Starter neurons are identified based on the coexpression of his-EGFP

and RV-dsRed. Input neurons only express RV-dsRed. **B.** AAV-hepler and RV-dsRed

expression in input neurons in representative sections of the ACC. **C.** Tracing of input

to ACC PV interneurons in PV-Cre animals (top) and tracing of input to ACC SST

interneurons in SST-Cre animals (bottom). Typical images indicate starter neurons in

the ACC coexpressing AAV-helper (his-EGFP, oRVG), RV-dsRed and PV or SST (gray).

D. PV neurons in the ACC receive direct inputs from the LPMR (top), and SST neurons in the ACC receive direct inputs from the vHPC (bottom). Images from a representative animal from each group. **E.** Targeting of the principal starter neurons (expressing his-EGFP and RV-dsRed) to the ACC subregions in the animals. 1.00 indicates all detected starter neurons. **F.** Analysis of the density of positive cells (RV-dsRed) in the upstream brain region. Data are presented as the mean ± s.e.m.
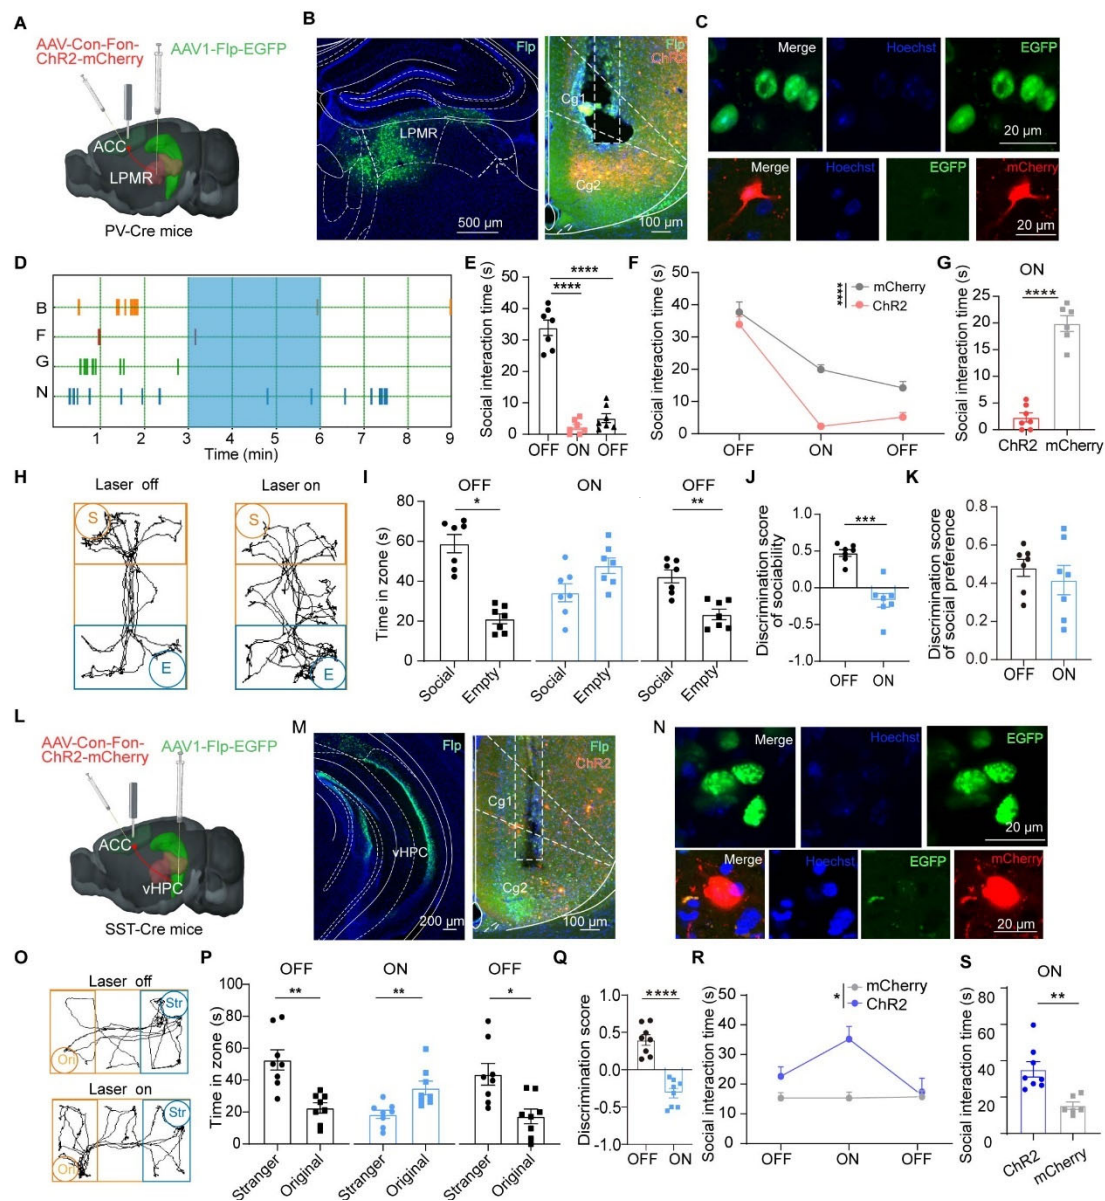

Fig. 7 Selective activation of the LPMR-PV (ACC) projection or vHPC-SST (ACC) projection produces distinct impairments in social interaction. A. Schematic of AAV1-Flp-EGFP injection into the LPMR and Con-Fon-ChR2-mCherry injection into the ACC of PV-Cre mice and optic fiber for laser embedding into the ACC. **B.** Representative micrograph showing the injection site in LPMR (left) and representative micrograph showing the site of optic fiber in ACC (right). **C.** AAV1 expression in LPMR (top) and AAV1-EGFP and ChR2-mCherry colabeled neurons in the ACC (bottom) of PV-Cre mice. **D-E.** Change process of different social interaction types in home cage when stimulus of PV-Cre mice (**D**) and quantification of social interaction

time in the home cage showing the effect of the laser on restraint of social time (**E**). **F-G.** Changes between the ChR2-mCherry and mCherry-control groups (**F**) and quantification of social time in **F** when laser on (**G**). **H.** Representative traces of sociability in the three-chamber of PV-Cre mice before laser on (left) and during laser on (right). **I.** Summary data of the active social recognition test showing that mice spent more time in the social zone (left panel) before laser on, no significant when laser on (middle panel) and preferred in the social zone after laser on (right panel). **J.** Discrimination score between laser off and laser on showing that activation of LPMR-PV (ACC) decreases active social interaction. **K.** Discrimination score between laser off and laser on showing that activation of vHPC-PV (ACC) has no influence on social preference. **L.** Schematic of AAV1-Flp-EGFP injection into the vHPC and Con-Fon-ChR2-mCherry injection into the ACC of SST-Cre mice and optic fiber for laser embedding into the ACC. **M.** Representative micrograph showing the injection site in the vHPC (left) and representative micrograph showing the site of optic fibers in the ACC (right). **N.** AAV1 expression in the vHPC (top) and AAV1-EGFP and ChR2-mCherry co-labeled neurons in the ACC (bottom) of SST-Cre mice. **O.** Representative traces of social preference in the three-chamber of SST-Cre mice before laser on (top) and during laser on (bottom). **P.** Summary data of the social preference test showing that mice spent more time in the stranger zone (left panel) before laser on, spent more time in the original zone when laser on (middle panel) and preferred the stranger zone after laser on (right panel). **Q.** Discrimination score between laser off and laser on showing that mice prefer social in original zone to in stranger zone when laser on. **R-S.** Change process between the ChR2-mCherry and mCherry-control groups in the original zone (**R**) and comparison of social interaction time between ChR2-mCherry and mCherry-control groups when laser on (**S**). Data are presented as the mean $\pm$ s.e.m. *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$.

941

Methods

Mice. All experimental procedures were approved by the Institutional Animal Care and
Use Committee (IACUC) of the Fourth Military Medical University (Approval No.
IACUC-) and carried out according to the "Principles of Medical Laboratory Animal
Care" issued by the National Ministry of Health in China. Adult (6–8 weeks old) male
PV-Cre (Jax Stock no. 008069), SST-Cre (Jax Stock no. 013044), PV-tdtTomato (Jax
Stock no. 027395), Ai9 (Jax Stock no. 007909), *Shank3B*[-/-22] (Jax Stock no. 017688)
and C57BL6 mice were used in this study. The animals were housed in a 12 h:12 h
light–dark cycle (lights on at 8 AM) with food and water provided ad libitum.
According to the double-blind principle, the experimenters were blinded to the
experimental group.

Viral injections. *General procedure*. The mice were anesthetized with 1%
pentobarbital sodium and placed in a stereotaxic instrument (RWD). Erythromycin eye
ointment and a piece of silver paper were applied to prevent corneal drying. A
thermostatic heating pad (ThermoStar, RWD) was placed under the body to keep the
temperature constant during surgery. A small craniotomy hole was made using a dental
drill (RWD), and injections were performed via a microsyringe pump (KD Scientific)
at a flow rate of 40 nl/min to avoid potential damage to local brain tissue.

Optogenetics control behavior. AAV2/9-DIO-ChR2-EYFP was injected unilaterally
into the ACC of PV-Cre or SST-Cre mice (virus titer: 3.2E+12 vg/mL, 240 nl/injection;
AP: +0.73 mm; ML: -0.28 mm; DV: -1.75 mm, and optical fibers (2.5 mm optical
density (OD), 0.37 numerical aperture (NA), 2.0 mm length) were implanted
ipsilaterally.

Retrograde RV tracing of monosynaptic input of PV or SST interneurons to the ACC. A
mixture of rAAV-EF1a-DIO-His-EGFP-T2A-TVA and rAAV-EF1a-DIO-oRVG (1:1
ratio, a total of 200 nl) was injected unilaterally into the ACC of PV-Cre or SST-Cre
mice as a previous site to specifically infect monosynaptic input of PV interneurons or

969 SST interneurons. After three weeks, RV-EnvA-ΔG-dsRed was injected at the same

970 coordinates. This viral strategy assures effective generation of RV and optimization of

971 retrograde spread of RV-dsRed[86].

972 *Functional verification of the projection loop.* For synaptic tracing of LPMR to PV

973 interneurons in the ACC and vHPC to SST interneurons in the ACC and confirmation

974 of the role of projection, a mixture of rAAV2/1-Retro-ChR2 (5.08E+12 vg/mL) and

975 rAAV-CAG-FLEX-GCaMP7s (2.21E+12 vg/mL) was injected into the ACC of PV-Cre

976 and SST-Cre mice. Optical fibers were implanted in the ipsilateral LPMR (AP: -1.95

977 mm; ML: -1.64 mm; DV: -2.52 mm, 2.5 mm optical density (OD), 0.37 numerical

978 aperture (NA), 3.0 mm length) or vHPC (AP: -3.2 mm; ML: -3.81 mm; DV: -1.57 mm,

979 2.5 mm optical density (OD), 0.37 numerical aperture (NA), 4.0 mm length) with 15°

980 gradient and optical fibers (2.5 mm optical density (OD), 0.5 numerical aperture (NA),

981 2.5 mm length) were implanted ipsilaterally in ACC.

982 To confirm the function of these two projections *in vitro*, rAAV-hSyn-ChR2-mCherry

983 (3.84 E+12 vg/mL) was injected into the LPMR or vHPC of PV-tdTomato or SST-Cre：：

984 Ai9 mice.

985 *Specific projection regulation.* For specific regulation of LPMR→PV interneurons and

986 vHPC→SST interneurons in the ACC, AAV1-Flp-EGFP (3.51 E+13 vg/mL) was

987 injected into the LPMR (AP: -1.95 mm; ML: -0.85 mm; DV: -3.15 mm) of PV-Cre mice,

988 and AAV1-Flp-EGFP was injected into the vHPC (AP: -3.2 mm; ML: -3.2 mm; DV: -

989 2.8 mm) of SST-Cre mice. At the same time, rAAV-hSyn-Con-Fon-mCherry (5.56 E+12

990 vg/mL) was injected into the ACC of PV-Cre or SST-Cre mice, and optical fibers (2.5

991 mm optical density (OD), 0.37 numerical aperture (NA), 2.0 mm length) were

992 implanted ipsilaterally.

993 **Fiber photometry.** Fiber photometry was used to record calcium signals using a

994 commercialized fiber photometry system (Thinker Tech). rAAV-CAG-FLEX-

995 GCaMP7s (2.21E+12 vg/mL) was injected unilaterally into the ACC of PV-Cre or SST-

996 Cre mice as previously described, and optical fibers (2.5 mm optical density (OD), 0.5

997   numerical aperture (NA), 2.5 mm length) were implanted ipsilaterally. We used dental

998   acrylic (Super Bond) to support the ceramic ferrule. Mice were individually housed and

999   allowed to recover for at least 1 week. To record fluorescence signals, GCaMP7s

1000   fluorescence was detected through the optic fiber using a fiber photometry system

1001   (Thinker Tech). The values of fluorescence change ($\Delta F/F_0$) were calculated by

1002   calculating $(F - F_0)/F_0$. The MATLAB-based software provided by Thinker Tech

1003   Company was used to analyze the results.

1004   **Behavioral tests and *in vivo* optogenetic manipulations.** For optical stimulation,

1005   during behavioral tests, the device connection process is described above[22]. Mice were

1006   connected to the patch cable, which was connected through a fiber-optic rotary joint

1007   allowing free rotation of the fiber and then allowed to recover from handling before the

1008   behavior test was initiated. In the excitatory photogenetic experiment, the test was

1009   divided into three 3 min epochs: laser stimulation off, on and off (OFF-ON-OFF

1010   epochs). Photoactivation of PV interneurons or SST interneurons in the ACC was

1011   induced by 40 Hz light trains with 5 ms pulses of blue light generated by a 473 nm laser.

1012   *Social interaction in the home cage.* This procedure was carried out as previously

1013   described[22]. One week before the experiment, we grasped the test mice every day to

1014   perform adaptability training. Mice were allowed to explore the home cage freely for 3

1015   min (habituation) before an unfamiliar juvenile male mouse (3 weeks old) was

1016   introduced into the cage. Measured social interaction behaviors included body sniffing,

1017   anogenital sniffing, face or nose contact and close following (<1 cm) initiated by the

1018   test mouse. All behaviors were video-recorded and analyzed using SMART v.3.0

1019   software by experimenters who were blinded to the testing conditions.

1020   *Three-chamber test.* This procedure was carried out as previously described[22]. The

1021   apparatus was made of black perspex and consisted of three identical chambers (30 cm

1022   × 45 cm × 20 cm). Two cylindrical grid cages were placed in the corners of the outer

1023   chambers, allowing free interaction (visual, olfactory, and auditory) between the test

1024   mouse and caged mouse. Before the test, the test animal was placed in the chamber for

1025   10 min to habituate then isolated in the middle area to wait for the experiment to begin.

1026   For the sociability test, a novel juvenile male mouse was placed in a wire cage placed

1027   in one corner of the chamber, and another empty wire cage was placed in the opposite

1028   corner. For the social preference test, anther stranger juvenile male mouse was put into

1029   an empty cage, and then the experimental subject was allowed to explore freely in three

1030   chambers. The time spent in each chamber and the time spent in close proximity to the

1031   wire cages were analyzed using SMART v.3.0 software.

1032   *Olfactory test.* Urine collection as previously describe[87]. The experiment was carried

1033   out in open field. Urine filter paper and saline filter paper were placed on opposite sides

1034   of the open field to record the movement of mice when laser off and laser on. The time

1035   spent in each corner were analyzed using SMART v.3.0 software.

1036   *Virus intervention social behavior experiments.* Before AAV-taCasp3 injection, all PV-

1037   Cre and SST-Cre mice underwent a pre-experiment, including social interaction in the

1038   home cage and three-chamber test. After that, AAV-taCasp3 (2.03E+12 vg/mL) was

1039   injected into the ACC. After three weeks, a new round of social interaction experiments

1040   was conducted again. The time spent with unfamiliar juvenile male mice in the home

1041   cage and in three chambers in close proximity to the wire cages was analyzed using

1042   SMART v.3.0 software. These results were compared before and after virus injection.

1043   **Immunocytochemistry.** All animals were anesthetized with 1% pentobarbital sodium

1044   and perfused intracardially with 0.9% saline followed by 4% paraformaldehyde. Then,

1045   the whole brain was removed and placed in 30% sucrose solution for 3 days. For PV

1046   interneurons or SST interneurons labeling, 40 μm cryostat sections containing the ACC

1047   were placed in blocking solution for 1 h before incubation in primary antibody against

1048   PV (rabbit, 1:100, Abcam, ab181086), primary antibody against SST (rat, 1:50,

1049   Millipore, MAB354), primary antibody against KCNH7 (rabbit, 1:50, Proteintech,

1050   13622-1-AP), and primary antibody against NeuN (mouse, 1:500, Abcam, ab104224)

1051   overnight at room temperature. One hour after the behavior test, the whole brain

1052   samples were perfused, and these samples were stained for Fos (rabbit, 1:1500, CST,

1053 #2250). Sections were then incubated with the corresponding secondary antibody at a
1054 dilution of 1:800 for 4 h at room temperature. Finally, all sections were incubated with
1055 Hoechst 33342 (Sigma) and were rinsed in 0.01 M PBS and cover-slipped with a
1056 mixture of 50% (v/v) glycerol in 0.01 M PBS.

1057 **VS200 continuous section scanning observation.** After 7 days of injection with RV-
1058 EnvA-ΔG-dsRed, the animals were anesthetized with 1% pentobarbital sodium and
1059 perfused intracardially with 0.9% saline followed by 4% paraformaldehyde, and the
1060 whole brain was removed. After samples and sinking completely in 30% sucrose
1061 solution, the whole brain was cut into 40 μm sections on a cryotome (Leica). All
1062 sections were incubated with Hoechst 33342 (Sigma) and were rinsed in 0.01 M PBS
1063 and cover-slipped with a mixture of 50% (v/v) glycerol in 0.01 M PBS. Then, we used
1064 VS200 continuous section scanning (Olympus) to obtain images and counted the
1065 positive cells by OlyVIA (Olympus).

1066 **RNA extraction and quantitative real-time PCR.** To verify the efficiency of AAV-
1067 taCasp3, we used a real-time PCR procedure to detect the mRNA levels of *parvalbumin*
1068 and *somatostatin* as previously described[88]. After the social behavior test, the mice were
1069 deeply anesthetized with isoflurane and sacrificed. The mouse skull was opened, and
1070 the whole brain was removed. Fresh ACC tissues were isolated from the corresponding
1071 coronal sections under a stereomicroscope. Total RNA was extracted with TRIzol
1072 reagent, and PrimeScript^TM RT Master Mix (Takara) was used to reverse transcribe the
1073 total RNA (500 ng) into complementary DNA. Real-time PCR was carried out using a
1074 StepOnePlus^TM Real-Time PCR Instrument (Thermo) with 2X Universal SYBR Green
1075 Fast qPCR Mix (ABclonal). The sequences of the primers used were as follows:

Target gene	F-	R-
GAPDH	GCGAGACCCCACTAACATCAA	GTGGTTCACACCCATCACAAA
Parvalbumin	GGGCCTGAAGAAAAAGAACC	TTCTTCAACCCCAATCTTGC
Somatostatin	ACCGGGAAACAGGAACTGG	TTGCTGGGTTCGAGTTGGC

1076

Physiological recording from brain slices. *General procedure*. For brain slice preparation, the mice were deeply anesthetized withisoflurane, and coronal sections (300 μm thick) containing the ACC were cut using a vibratome (7000SMZ, Campden) in transcardially perfused with ice-cold carbogenated cutting solution containing 115 mM choline chloride, 2.5 mM KCl, 1.25 mM NaH_2PO_4, 0.5 mM $CaCl_2$, 8 mM $MgCl_2$, 26 mM $NaHCO_3$, 10 mM D-(+)-glucose, 0.1 mM L-ascorbic acid, and 0.4 mM sodium pyruvate (pH 7.4, with osmolarity of 295–300 mOsm/L). Then, brain slices were recovered for 30 min and incubated with carbogenated cutting solution (95% O_2, 5% CO_2) in a holding chamber at 32 °C. After that, the brain slices were recovered for 1 h at room temperature in artificial cerebral spinal fluid (ACSF) (119 mM NaCl, 2.3 mM KCl, 1.0 mM NaH_2PO_4, 26 mM $NaHCO_3$, 11 mM D-(+)-glucose, 1.3 mM $MgCl_2$, and 2.5 mM $CaCl_2$ (pH 7.4, with osmolarity of 295–300 mOsm/L). After recovery, the slices were placed in the recording chamber and continuously perfused with ACSF. The recordings were obtained using a Multilamp 700B amplifier (Molecular Devices) filtered at 5 kHz and sampled at 20 kHz with a Digidata 1550B. Clampex 10.7 was used for acquisition and analysis.

Optical evoked spikes with ChR2. Patch pipettes were filled with a solution containing the following: 128 mM potassium gluconate,10 mM Na-phosphocreatine, 10 mM HEPES, 1.1 mM EGTA, 0.5 mM Na_2GTP, and 5 mM MgATP (pH 7.3, 300–305 mOsm/L). The cell membrane potential was clamped at −65 mV to record changes in spikes induced by ChR2 with 40 Hz stimulation.

Optical IPSCs. Patch pipettes were filled with a solution containing the following: 103 mM CsCl, 12 mM CsMeSO3, 12 mM CsOH, 12 mM methanesulfonic acid, 5 mM TEA-Cl, 10 mM HEPES, 4 mM MgATP, and 0.3 mM Na_2GTP (pH 7.3, 300–305 mOsm/L). Clamping the pyramidal neuron surrounded by fluorescence and the cell membrane potential was clamped at −65 mV and stimulated with ChR2-recording IPSCs in pyramidal neurons. 100 μM picrotoxin (PTX) was perfused verifying IPSCs property.

Intrinsic membrane properties. To measure the intrinsic membrane properties of PV interneurons and SST interneurons in the ACC, patch pipettes were filled with a solution containing as *Optical evoked spikes with ChR2.* Whole-cell recordings were carried out in current-clamp mode at −65 mV, and spikes were induced by incrementally increasing the current injection (each step increase was 20 pA).

Optical EPSCs. Patch pipettes were filled with a solution containing the following: 120 mM $CsMeSO_3$, 10 mM TEA-Cl, 5 mM NaCl, 10 mM HEPES, 4 mM MgATP, 0.3 mM Na_2GTP, 1.1 mM EGTA, and 4 mM lidocaine (pH 7.28, 295–300 mOsm/L). The laser intensity was adjusted to obtain a maximal response without overstimulation, and 0.5 ms blue light was applied with the cells clamped at −65 mV. Additional 1 μM tetrodotoxin (TTX) and 100 μM 4-AP were perfused followed by 20 μM NBQX to check whether the light-evoked PSCs were excitatory or inhibitory.

The excitability modulated by ERG3 channel. To observe the role of the ERG3 channel in active potential, 1-[2-(6-methyl-2-pyridyl)ethyl]-4-(4-methylsulfonylaminobenzoyl) piperidine (E-4031, Tocris), a blocker of ERG, was added to ACSF solution. Stock solutions of E-4031 (100 μM) were prepared in DMSO before dilution in ACSF; the final DMSO concentration never exceeded 0.1%, a concentration at which it did not affect the membrane potential and membrane currents.

Kv11 current recordings. For voltage-dependent K^+ current recordings, the low K^+ intracellular solution was composed of 55 mM potassium methanesulfonate, 5 mM KCl, 73 mM N-methyl-d-glucamine, 5 mM NaCl, 0.5 mM EGTA, 30 mM HEPES, 4 mM MgCl2, 4 mM MgATP and 0.4 mM Na_2GTP (pH 7.4, adjusted with HCl)[89]. For recording Kv11 currents from PV or SST-positive neurons in the ACC, 1 μM tetrodotoxin (TTX), 20 μM NBQX, 50 μM D-AP5 and 10 μM bicuculline were also supplemented in high K^+ intracellular solutions (10 mM KCl and no Ca^{2+}). These high K^+ extracellular and low K^+ intracellular solutions enable K^+ currents to be recorded as large, distinct inward currents. The signals were filtered at 3 kHz and digitized at 10 kHz in experiments for measuring Kv11 currents. The activation curve of the ERG

1133 channels was extracted by dividing the peak amplitudes of E-4031-sensitive tail current

1134 traces at 0.5 ms after the voltage was changed to -100 mV.

1135 **scRNA-seq**. *10X sample processing and cDNA library preparation.* From the fresh

1136 frozen mouse brain, two groups of ACC tissue were rapidly dissected from the cortex

1137 of *Shank3* KO and WT mice. Samples were homogenized in ice-cold homogenization

1138 buffer (0.25 M sucrose, 5 mM CaCl2, 3 mM MgAC2, 10 mM Tris-HCL pH 8.0, 0.1

1139 mM EDTA, 1x protease inhibitor, and 1 U/µl ribolock RNase inhibitors) with a glass-

1140 on-glass dounce homogenizer prepared for extract nuclei. This process has been

1141 reported before[90].Nuclei concentration was adjusted to 1000 nuclei/µL and followed

1142 immediately by the 10X Genomics® Single Cell Protocol. Cellular suspensions were

1143 loaded on a 10X Genomics GemCode Single-cell instrument that generates single-cell

1144 Gel Bead-In-EMlusion (GEMs). Libraries were generated and sequenced from the

1145 cDNAs with Chromium Next GEM Single Cell 3' Reagent Kits v3.1. The cDNA

1146 libraries were sequenced on the Illumina sequencing platform by Genedenovo

1147 Biotechnology Co., Ltd (Guangzhou, China).

1148 *Sequencing and Cell Clustering.* The Single Cell 3' Protocol produced Illumina-ready

1149 sequencing libraries. The cell-by-gene matrices for each sample were individually

1150 imported to Seurat version 3.1.1 for downstream analysis.

1151 *Differentially expressed gene analysis.* The expression value of each gene in a given

1152 cluster was compared against the rest of the cells using the Wilcoxon rank sum test[91].

1153 **Fluorescent in situ hybridization.** Mice were deeply anesthetized with isoflurane and

1154 transcardially perfused with 0.01 M PBS (pH: 7.4), followed by 4% paraformaldehyde

1155 in 0.01 M PBS. The brains were removed and fixed in 4% paraformaldehyde for 2 h

1156 and then put into 10%, 20%, 30% sucrose sequentially at 4°C until they sank to the

1157 bottom of the container. Frozen, 10 µm, coronal sections were cut on a cryostat (Leica).

1158 RNAscope in situ hybridizations were performed according to the manufacturer's

1159 instructions, using the RNAscope™ Multiplex Fluorescent Reagent Kit v2 for fixed-

1160 frozen tissue. Briefly, sections were dehydrated in sequential incubations with ethanol,

followed by 30 min Protease III treatment and washing in ddH$_2$O. Appropriate combinations of hybridization probes [here gene target name (mouse) and catalogue number: *Pvalb* 421931-C1, *Sst* 404631-C1 and *Kcnh7* 1007281-C2, ACD] were incubated for 2 h at 40 °C, followed by three amplification steps and incubated each channel with a specific color. Hoechst counterstaining and mounting with antifade mounting medium.

Single-cell qRT–PCR. Single PV-positive or SST-positive neurons in the ACC with red fluorescence signals were aspirated by a patch clamp. Each single cell was ejected into a tube with 5 µL of DPBS. Total RNA and cDNA from single neurons were isolated using a REPLI-g® WTA Single Cell kit (Qiagen) according to the manufacturer's instructions. qRT–PCR was performed with SYBR® Premix Ex Taq (ABclonal) in a CFX96 Touch Real-time PCR Detection System (Bio-Rad). Primer sequences are listed as follows:

Gapdh-Fp: 5′-AGGTCGGTGTGAACGGATTTG-3′,

Gapdh-Rp: 5′-TGTAGACCATGTAGTTGAGGTCA-3′;

Kcnh7-Fp: 5′-CCAGGAAACTGGACCGATACT-3′,

Kcnh7-Rp: 5′-CCAATCGCATACCAGATGCAA-3′;

Kcnh6-Fp: 5′-GACGTGCTTTCCACTCTCTAC-3′,

Kcnh6-Rp: 5′-GCGCTTGATTTGCCTGGTC-3′;

Kcnv2-Fp: 5′-ATGGTCCTTGAGCTACAAGCC-3′,

Kcnv2-Rp: 5′-CCCCGCAGTCCTCATCTTC-3′.

CRISPR-Cas9. *In vivo genome editing. In vivo* knockdown experiments targeting *Kcnh7* employed an AAV CRISPR/Cas9 approach. The single guide RNA (sgRNA) with high specificity and high efficiency were computationally identified from sgRNA libraries for genome-wide CRISPR knockout screening. Three U6-sgRNA (FE) gene fragments with the F+E tracrRNA backbone were synthesized by Integrated DNA Technologies (sequences are provided below, spacer sequences are capitalized). These fragments were cloned into the pX552-EGFP plasmid by In-Fusion Snap assembly

1189   master mix (Takara 638948) to construct pX552-3xsgRNA(FE)-EGFP.

1190   The AAV vectors were serotyped with PHP.eB coat proteins (3.64×10^{13} genome

1191   copy (GC) ml-1 viral titers for). Briefly, sgRNA plasmids, pAdDeltaF6 (Addgene,

1192   plasmid #112867), and pUCmini-iCAP-PHP.eB (Addgene, plasmid #103005) were co-

1193   transfected into HEK293T cells using polyethylenimine (Cat. No. 23966, Polysciences).

1194   Cells were harvested 72 h post transfection by 5,000 x g centrifugation at 4°C for 10

1195   min. Virus in media was precipitated by 8% PEG8000 (89510-1KG-F, Sigma). Cell

1196   pellets and virus precipitated from media were re-suspended in digestion buffer

1197   containing 500 mM NaCl, 40 mM Tris base, and 10mM $MgCl_2$. Benzo nuclease (10

1198   KU, novoprotein) was added in the digestion buffer and incubated at 37 °C water bath

1199   for 1 hr. Next, we performed centrifugation at 2,000 x g for 10 min, and the supernatant

1200   was used on a discontinuous gradient of 15%, 25%, 40%, and 60% iodixanol in a 39

1201   mL ultracentrifuge tube (No. 344326, Beckman). Ultracentrifugation was performed at

1202   350,000 x g, 18°C for 2.5 hr. 5 mL fractions in 40% layer and 40%–60% interface was

1203   collected. These fractions were desalted using a 100 kDa cutoff ultrafiltration tube (15

1204   ml, Millipore). Buffer was exchanged 4 times with 1x PBS with 0.001% Pluronic F-68.

1205   AAV titers were determined by real-time quantitative PCR (qPCR) using the primers

1206   of ITR. Forward primer: 5' GGAACCCCTAGTGATGGAGTT 3'; Reverse primer: 5'

1207   CGGCCTCAGTGAGCGA 3'.

1226   **Statistical Analyses.** All statistical analyses were performed in Prism 6.0 (GraphPad
1227   Software, Inc., USA). Values were expressed as the means ±s.e.m. Data were tested for
1228   significance using either an unpaired t test or a two-way repeated-measures ANOVA.
1229   Normally distributed data sets were analysed using a 2-tailed unpaired t test and 2-way
1230   repeated-measures ANOVA, followed by Tukey's multiple comparisons test. Data sets
1231   that were not normally distributed were analysed with a Kruskal-Wallis test with
1232   adjustments for multiple comparisons (**Extended Tables 1**). All behavioural,
1233   electrophysiological, biochemical and morphological data were obtained by
1234   counterbalancing experimental conditions with controls. Details of particular statistical
1235   analyses can be found in **Extended Tables 1**. Statistical significance was accepted when
1236 $p < 0.05$.

1237   **Data availability.** The raw sequencing data of the scRNA-seq have been deposited in
1238   the Genome Sequence Archive in BIG Data Center (http://bigd.big.ac.cn/), Beijing
1239   Institute of Genomics (BIG), Chinses Academy of Sciences, under the accession
1240   number: **CRA013264**. The other datasets generated or analyzed during the present
1241   study are available from the corresponding author upon reasonable request.

1310 **Extended Data Fig. 7 The PV and SST interneurons in the ACC have different**

1311 **electrophysiological characteristics. A.** Schematic of DIO-ChR2 injection into the

1312 ACC of PV-Cre mice and SST-Cre mice. **B.** Schematic of recording IPSCs on pyramidal

1313 neurons by whole-cell recording. **C.** DIC display EYFP-labeled cells. **D.** IPSCs were

1314 induced by the laser on pyramidal neurons when stimulating PV interneurons (red) and

1315 could be blocked by PTX (gray, top); IPSCs were induced by the laser on pyramidal

1316 neurons when stimulating SST interneurons (green) and could be blocked by PTX (gray,

1317 bottom). **E.** Quantification of IPSC amplitude before and after PTX blocking in PV-Cre

1318 mice (left); quantification of IPSC amplitude before and after PTX blocking in SST-

1319 Cre mice (right). **F.** PPR traces induced by evoking PV interneurons (top) or SST

1320 interneurons (bottom). **G.** Quantification of PPR according to different stimulus

1321 intervals. **H.** Spike trace of PV interneurons (left) and SST interneurons (right). **I.**

1322 Comparison of spike frequency of different stimulus intensities between PV and SST

1323 interneurons. Data are presented as the mean ± s.e.m. *$p<0.05$, ****$p<0.0001$.

Extended Data Fig. 8 Both *in vitro* and *in vivo* results showed that the projections of LPMR to PV (ACC) and vHPC to SST (ACC) are glutamatergic. A. Schematic of syn-ChR2 injection into the ACC of PV-tdTomato mice and SST-Cre::Ai9 mice. **B.** Dotted frame indicating PV-tdTomato cells (left), 473 nm laser-induced EPSCs on PV-tdTomato cells (red) and blocked by NBQX (gray)(middle), and quantification of EPSC amplitude before and after NBQX blockade (right). **C.** Dotted frame indicating SST-Cre::Ai9 cells (left) and 473 nm laser-induced EPSCs on SST-Cre::Ai9 cells (green) and blocked by NBQX (gray), and quantification of EPSC amplitude before and after NBQX blockade (right). **D.** Schematic of injecting a mixture of retro-ChR2 and FLEX-GCaMP7s into the ACC of PV-Cre mice, optic fibers for laser embedding into the LPMR and optic fibers for fiber photometry embedding into the ACC. **E.** Representative micrograph showing the site of the optic fiber in the ACC (left); representative micrograph showing the site of the optic fiber in the LPMR and showing the expression of ChR2 (right). **F.** Typical Ca^{2+} signal trace induced by a 473 nm laser in PV-Cre mice. **G.** Schematic of injecting a mixture of retro-ChR2 and FLEX-GCaMP7s into the ACC of SST-Cre mice, optic fibers for laser embedding into the vHPC and optic fibers for fiber photometry embedding into the ACC. **H.** Representative micrograph showing the site of the optic fiber in the ACC (left); representative micrograph showing the site of the optic fiber in the vHPC and showing the expression of ChR2 (right). **I.** Typical Ca^{2+} signal trace induced by a 473 nm laser in SST-Cre mice.

1348   Data are presented as the mean ± s.e.m. $*p<0.05$, $***p<0.001$.

1349
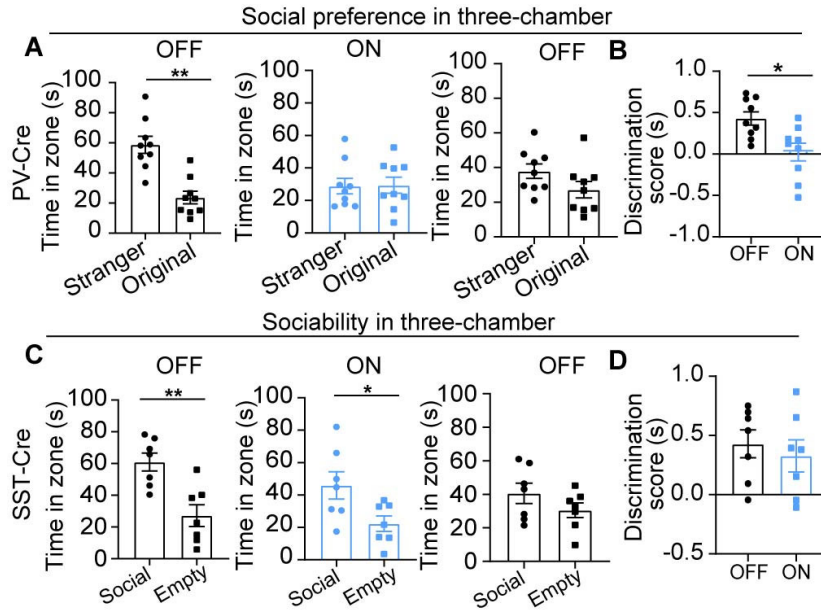

Extended Data Fig. 9 Specific activating LPMR-PV (ACC) projection or vHPC-SST (ACC) projection have no change on social preference or sociability, respectively. A. Summary data of the active social preference test showing that PV-Cre mice spent more time in the stranger zone (left panel) before laser on, no significant when laser on (middle panel) and no significant after laser on (right panel). **B.** Discrimination score between laser off and laser on showing that activation of LPMR-PV (ACC) decreases social time in the stranger zone. **C.** Summary data of the sociability test showing that SST-Cre mice spent more time in the social zone (left panel) before laser on and when laser on (middle panel) and no significant after laser on (right panel). **D.** Discrimination score between laser off and laser on showing no significant change in social time in the social zone and after activation of vHPC-SST (ACC). Data are presented as the mean ± s.e.m. *$p<0.05$, **$p<0.01$.
