20

21 **Abstract**

22 **Background:** The outcome and longitudinal course of inflammation and infection markers were  
23 unknown in COVID-19 patients on the ICU treated without (N) or with SARS-CoV-2 specific monoclonal  
24 antibodies (casirivimab / imdevimab, C) or antibodies against interleukin-6 (IL-6) receptors  
25 (tocilizumab, T), solely, or in combination of both (C + T).

26 **Methods:** In a retrospective observational study, in critically ill N, C, T, C+ T COVID-19 patients admitted  
27 to the ICU with the CoV-2 delta-variant between August 2021 and February 2022, 28-day mortality and  
28 30-day time course of infection and inflammation markers were evaluated.

29 **Results:** Out of 95 patients with COVID-19, 29 patients were not treated (N), 17 with C, 16 with T, 33  
30 with C + T. Mortality rates in N, C, T, and C + T, were 24%, 35%, 56%, and 24%, being higher in T  
31 compared to N and C + T ( $p = 0.05$ ). Prolonged leukocyte, procalcitonin (PCT), C-reactive protein (CRP)  
32 and interleukin 6 (IL-6) elevations were detected in nonsurvivors compared to survivors in C + T within  
33 the first two weeks, IL-6 in the first days in T. In N, higher PCT, CRP, IL-6 and ferritin occurred in  
34 nonsurvivors in the first days.

35 **Conclusion:** Sporadically measured IL-6 and CRP in T is less useful. Longlasting IL-6 receptor blockade  
36 may be deleterious in COVID-19. High IL-6 may hint at poor prognosis within the first days in T,  
37 leukocytes, PCT, CRP and IL-6 in the first two weeks in C + T, and PCT, CRP, IL-6 and ferritin within the  
38 first days in N.

39

40 **Trial registration:** ClinicalTrials.gov Identifier: NCT06233357, retrospectively registered, release date:  
41 January 31, 2024.

44 inhibitors; Mortality; Procalcitonin; Spike Glycoprotein; Tocilizumab;

45

46

## 47 **Background**

48 COVID-19 is a biphasic disease with viral replication and a high viral load in the initial phase overlapping  
49 after 5 -7 days with a following overwhelming hyperinflammatory phase with immune mediated  
50 damage in severe cases (1). In the initial phase, SARS-CoV-2 specific monoclonal antibodies  
51 (casirivimab and imdevimab) have been advised in guidelines for IgG-seronegative patients with  
52 COVID-19 to reduce viral load (2, 3). In the hyperinflammatory phase, a humanized anti-human IL-6  
53 receptor (IL-6R) antibody (tocilizumab) has been recommended in rapid progressive disease (2-4).

54 The longitudinal course of leucocyte counts, procalcitonin (PCT), C-reactive protein (CRP) and IL-6 has  
55 been monitored in 16 COVID-19 patients treated with tocilizumab (5). Under tocilizumab, IL-6 serum  
56 concentrations peaked around day 3 – 5 and stayed elevated for many days. IL-6R blockade led to a  
57 sustained suppression for approximately 14 days rendering its clinical use as a biomarker of infection  
58 useless (“CRP-blind spot”). Leukocyte count and PCT were rather unaffected by tocilizumab. No  
59 differences between survivors and nonsurvivors were detected. The authors stated that the relevance  
60 of these phenomena has still not been elucidated in COVID-19 and should be seen in an individual  
61 context. Increased infection risk has been reported during blockade of IL-6R with bacterial, viral and  
62 opportunistic infections (6).

63 Between August 2021 and February 2022, critically ill COVID-19 patients admitted to the ICU of the  
64 Clinic for Anaesthesiology and Intensive Care Medicine at the University of Ulm with the CoV-2 delta-  
65 variant have been treated without or with casirivimab / imdevimab and / or tocilizumab solely or in  
66 combination, as advised by the COVID-19 guidelines at that time. However, outcome and course of  
67 infection and inflammation parameters during the ICU stay were unclear under treatment with  
68 casirivimab / imdevimab and / or tocilizumab solely or in combination.

69 Therefore, the present retrospective, observational study was performed to find out how many  
70 critically ill COVID-19 patients were treated without (N) or with casirivimab / imdevimab (C) or  
71 tocilizumab (T), solely, or in combination of both (C + T). Moreover, the present study should clarify

72 the length of stay on the ICU, outcome and longitudinal course of infection and inflammation  
73 parameters in these four groups, and whether there are differences in survivors and nonsurvivors. We  
74 focus on the time course of leukocyte counts, PCT, CRP, IL-6 and ferritin serum concentrations during  
75 the ICU stay.

76 We hypothesized that mortality would increase from patients without indication for C or T, over those  
77 with C, T up to C + T. It was expected that under application of C, infection and inflammation markers  
78 would be lower over time than in T and C + T. In patients with T, high serum concentrations of IL-6 and  
79 low ones of CRP over time were expected, and probably higher infection markers. Moreover, higher  
80 infection and inflammation markers were expected in nonsurvivors compared to survivors in the four  
81 groups.

82

## 83 **Methods**

### 84 **Study subjects**

85 In a retrospective observational study, critically ill COVID-19 patients admitted to the ICU with the CoV-  
86 2 delta-variant between August 2021 and February 2022 were evaluated. The study was approved,  
87 and informed consent waived due to the retrospective study design using routine clinical and  
88 laboratory data, by the ethics commission of the university Ulm (ethics application nr. 129/22). All  
89 methods were performed in accordance with the relevant guidelines and regulations. The study has  
90 been performed in accordance with the Declaration of Helsinki. The study was registered under the  
91 ClinicalTrials.gov identifier NCT 06233357.

92 IgG seronegative SARSCoV2-Spike antibody (< 0,80 U/ml) COVID-19 patients were treated with one  
93 dose of subcutaneous casirivimab and imdevimab, 1200 mg (600 mg of each). Patients with CRP > 75  
94 mg/l or IL-6 > 75 ng/l were treated with one dose of intravenous tocilizumab 8 mg/kg body weight.

95

96 **Study specific assessments**

97 Due to the National Institute of Allergy and Infectious Diseases (NIAID) and WHO ordinal scale (7),  
98 patients with SARSCoV-2 infection and COVID-19 disease are classified to suffer from critical illness and  
99 have respiratory failure, septic shock, and/or multiple organ dysfunction. With WHO ordinal scale 4,  
100 patients are hospitalized and receive oxygen by mask or nasal canula, with 5 need non-invasive  
101 ventilation or high-flow oxygen, with 6 intubation and mechanical ventilation, with 7 ventilation and  
102 additional organ support, such as vasopressors, renal replacement therapy or extracorporeal membrane  
103 oxygenation (ECMO), and 8 represents death. These stages were associated with high risks of  
104 overwhelming health care systems and mortality (8, 9).

105 28-day mortality and 30-day time course of routine laboratory data, i.e., leukocyte counts and serum  
106 concentrations of CRP, PCT, IL-6 and ferritin in four patient groups, i. e., N, C, T, C+ T, were evaluated.  
107 Missing data were not replaced.

108

109 **Statistical analyses**

110 Comparisons of parameters are presented as box-plots with median values, 25%-percentiles and 75%-  
111 percentiles, minimal and maximal values. For the comparison of frequencies between the N, C, T and  
112 C + T groups, contingency tables with 95% confidence intervals (95% CI) are given. Mann-Whitney test  
113 was used for comparisons of independent unpaired values. For the comparison of frequencies  
114 between the four groups, Fisher's exact test with contingency tables with 95% CI for odds ratios are  
115 given. p-values below 0.05 were considered statistically significant.

116

117

118 **Results**

119 **Clinical Effects**

120 In total, 102 COVID-19 patients were admitted to the ICU. In seven patients, laboratory data were  
 121 available for one day, only. Thus, 95 patients remained for evaluation. Out of these 95 patients, 29  
 122 patients were not treated with C and/or T (N), 17 with C, 16 with T, 33 with C + T. Patient baseline  
 123 characteristics and risk factors of the four patient groups are summarized in Table 1. (Please see Table  
 124 1 at the end of the text file, and put Table 1 in here). Length of stay on the ICU in N, C, T, and C + T, was

131 Absolute (n) and relative (%) mortality frequencies are presented. Bold numbers highlight marked  
132 differences between groups. *C* Casirivimab, *T* Tocilizumab, *C + T* Casirivimab + Tocilizumab, *N* Without  
133 Casirivimab / Tocilizumab, *n* numbers, *OR*, odds ratio, *95%CI*, 95% confidence interval  
134 in median 6, 5, 7 and 15 days, respectively (Table 2). Mortality rates in N, C, T, and C + T, were 24%,  
135 35%, 56%, and 24%, respectively.

136 Absolute and relative frequencies of the four patient groups regarding mortality are presented in Table  
137 3. Four-times higher odds ratios for mortality were detected in the T group than in the N as well as  
138 the C + T group (Table 3).

139

#### 140 **Effects on inflammation and infection markers**

##### 141 **Comparison of the four patient groups**

142 Compared to day 0, leukocytes were increased up to 30 days in C and C + T, in contrast to T and N  
143 (Table 4, Figs. 1, 3). No differences compared to day 0 were detected in the C, T and C + T groups, lower  
144 values in N in the third week regarding PCT (Table 4, Figs. 1, 4). CRP values were lower than day 0 in N,  
145 and profoundly lower in T and C + T up to 30 days (Table 4, Figs. 1, 5). IL-6 serum concentrations  
146 compared to day 0 did not differ in C, were higher in C + T within the first two weeks and, lower in T  
147 and N from the third week onwards, especially in nonsurvivors (Table 4, Figs. 2, 6). Regarding ferritin,  
148 no differences compared to day 0 were detected in C and C + T, and lower values from the third and  
149 fourth week onwards in N and T, especially in nonsurvivors (Table 4, Figs. 2, 7).

150

##### 151 **Comparison of survivors and nonsurvivors in the four patient groups**

152 Regarding leukocytes, no differences between survivors and nonsurvivors were detected in the C, T,  
153 and N group (Fig. 3). Leukocyte counts were lower in survivors than in nonsurvivors from day 8 to 10  
154 in the C + T group.

155 PCT serum concentrations did not differ between survivors and nonsurvivors in the C and T group, and

156 **Table 4** Time-course of infection and inflammation parameters in COVID-19 patients without/with  
 157 casirivimab/imdevimab and/or tocilizumab

Intervention	Patients	Comparison day 0 vs. days 1 – 30 (↓, ↑, p < 0.05)

158 Comparison of the time-course of infection and inflammation parameters in COVID-19 patients  
 159 without or with casirivimab / imdevimab and / or tocilizumab. ↓ values day 1 – 30 lower than day 0,  
 160 ↑ values day 1 – 30 higher than day 0. Bold signs and numbers highlight different direction of response  
 161 compared to other groups

162 were lower in survivors than in nonsurvivors from day 2 to 10 in the C + T group, and from day 1 to 5  
 163 in the N group (Fig. 4).

164 CRP serum concentrations did not differ between survivors and nonsurvivors in the C and T group, and  
 165 were lower in survivors than in nonsurvivors from day 5 to 9 in the C + T group, and from day 1 to 4 in  
 166 the N group (Fig. 5).

167 IL-6 serum concentrations did not differ between survivors and nonsurvivors in the C group, and were  
 168 lower in survivors than in nonsurvivors on days 0 to 2 and 5 in the T group, and from day 1 to 7 in the  
 169 C + T group and on day 0 and 1 in the N group (Fig. 6).

170 Ferritin serum concentrations did not differ between survivors and nonsurvivors in the C, T and C + T  
 171 groups, and were lower in survivors than in nonsurvivors from day 0 to 3 in the N group (Fig. 7).

172 Differences between survivors and nonsurvivors in infection and inflammation parameters over time  
 173 in COVID-19 patients in the four groups without or with C and / or T are summarized in Table 5.

174 **Table 5** Infection and inflammation parameters over time in COVID-19 survivors and nonsurvivors  
 175 without/with casirivimab/imdevimab and/or tocilizumab

Parameter	Days with values of survivors < nonsurvivors, p < 0.05			
	Casirivimab	Tocilizumab	Casirivimab + Tocilizumab	No Casirivimab/ Tocilizumab
Leukocytes			8 - 10	
Procalcitonin, PCT			2 - 10	1 - 5
C-reactive protein, CRP			5 - 9	1 - 4
Interleukin 6, IL-6		0 – 2, 5	1 - 7	0 - 1
Ferritin				0 - 3

176 Days and time frames are presented in which infection and inflammation parameters in survivors  
 177 were markedly lower (p < 0.05) than in nonsurvivors within the four COVID-19 groups.

## 178 Discussion

179

180 The main results of the present study are that there may be high numbers of critically ill COVID-19  
181 patients who need distinct immunomodulatory therapies and will have divergent time course of  
182 infection and inflammatory markers and prognosis. The usefulness of IL-6 and CRP in T patients as  
183 clinical markers will be limited, if used sporadically and not on a longitudinal basis. Since T patients had  
184 the highest mortality rate, longlasting IL-6 receptor blockade may be deleterious in critically ill COVID-  
185 19 patients. High IL-6 values within the first days in T patients may hint at poor prognosis. Prolonged  
186 leukocyte, PCT, CRP and IL-6 elevations in the first two weeks may depict nonsurvivors in C + T patients.  
187 High PCT, CRP, IL-6 and ferritin within the first days may be associated with poor prognosis in N  
188 patients.

189 The hyperinflammatory phase is characterized by an increase in proinflammatory cytokines and  
190 mediators, such as IL-2, IL-6, TNF-alpha, G-CSF, CRP and Ferritin (10, 11). IL-6 and ferritin play a major  
191 role in the pathophysiology of COVID-19. Regulatory proteins of SARS-CoV2 use iron. Ferritin is  
192 involved in iron dependent defense mechanisms to bacterial and viral infections, reducing iron  
193 dependent growth of bacteria and replication of virus. Elevated ferritin levels in diseases with  
194 hyperinflammation, such as virus triggered HLH, sepsis or organ failure may hint at the  
195 hyperinflammatory phase in COVID-19 (12, 13). In severe COVID-19, ferritin serum concentrations >  
196 300 ug/ml were associated with increased mortality (14). In addition, persistently high ferritin and IL-  
197 6 serum concentrations were detected in dying COVID-19 patients (14). Also, in the present study,  
198 ferritin serum concentrations were markedly higher in nonsurvivors than survivors in N, and IL-6 in T,  
199 C + T and N within the first days after admission on the ICU.

200 Casirivimab / imdevimab, a SARS-CoV-2 specific monoclonal antibody, reduced the duration of  
201 symptomatic disease and the duration of a high viral load among outpatient participants who became  
202 infected (15). Casirivimab / imdevimab reduced the risk of hospitalization or death compared with no

203 treatment in patients with mild to moderate COVID-19 in outpatient infusion centers caused by the  
204 SARS-Cov2 Delta variant (16-18). Additionally, in the present study, critically ill patients treated early  
205 with casirivimab, solely, had a low mortality rate, also.

206 Due to beneficial effects of low dose glucocorticoids (Recovery trial (NCT04381936) (19) on COVID-19  
207 hyperinflammation and getting standard of care in 2020, reducing proinflammatory signaling was  
208 expected to save patients' lives (20). In this context, IL-6 receptor blockade with tocilizumab and  
209 sarilumab including glucocorticoids in the majority of patients (>80%) revealed beneficial effects  
210 regarding respiratory and cardiovascular organ support-free days, and improved survival in patients  
211 requiring organ support, i. e. high-flow nasal cannulae, noninvasive and invasive ventilation and / or  
212 any vasopressors or inotropes within 24 hours after starting organ support in the ICU (21). In  
213 hospitalised COVID-19 patients with 82% receiving systemic corticosteroids with hypoxia and systemic  
214 inflammation (CRP > 75 mg/l), tocilizumab improved survival and other clinical outcomes such as  
215 discharge from hospital, regardless of the amount of respiratory support, and effects were additional  
216 to the benefits of systemic corticosteroids (22). In a metaanalysis with 27 trials, IL-6 antagonists were  
217 associated with lower 28-day all-cause mortality and no difference in secondary infections (23). On the  
218 other hand, in less severely ill patients, IL-6 blockade did not prove benefit in intubation rate,  
219 extracorporeal membrane oxygenation or death in several trials using IL-6 blockade (23-29).

220 Moreover, in the interpretation of IL-6, the dual effect as proinflammatory as well as anti-inflammatory  
221 cytokine has to be considered. In hyperinflammation in COVID-19, proinflammatory effects are  
222 assumed to be mediated via soluble IL-6 receptors (30-32). Thus, a decrease of IL-6 in the  
223 hyperinflammatory phase is desirable. Via membrane bound IL-6 receptors, anti-inflammatory and or  
224 regenerative functions are mediated, such as proliferation of the intestinal epithelium, inhibition of  
225 epithelial apoptosis and metabolic control in the liver (32). Thus, too pronounced decrease or  
226 inhibition of IL-6, or prolonged blockade of IL-6 receptors as with tocilizumab, may be deleterious  
227 regarding regeneration and healing. These effects might have contributed to the highest detected  
228 mortality rate found in the T group. The present study reassured the previously reported long lasting  
229 depression of CRP and IL-6 by tocilizumab (5). Thus, sporadic analyses of CRP and IL-6 may not be

230 helpful after tocilizumab application. However, longitudinal analyses manifested markedly lower IL-6  
231 in survivors than nonsurvivors within the first days in T, C + T and N, as well as lower CRP within the  
232 first days in N and the second week in C +T.

233 The strengths of the present study are that it reveals insights in a well-defined, critically ill COVID-19  
234 population treated in the initial and hyperinflammatory phase with the delta virus variant of CoV-2.  
235 The results may help to design future studies. The detected subgroups of patients might be a basis in  
236 future to evaluate results of clinical studies in highly heterogenous patient populations with different  
237 baseline risk and design studies in patients with infectious diseases with a hyperinflammation  
238 background to increase the number of responders and reduce harm.

239 One of the limitations to draw conclusions of the present study is the low number of patients within  
240 distinct subgroups of survivors and nonsurvivors. Thus, relevant differences may have been missed  
241 and significant differences may be overinterpreted. However, the results may be helpful to generate  
242 hypotheses. Patients were treated when C, T or C + T was indicated based on guidelines. Since there  
243 was no control group within the C, T and C+ T group, in the presented study, natural course of the  
244 disease cannot be excluded. However, the different patterns of cytokine decreases and increases  
245 reflect the major role of viral replication and IL-6 inhibition in the initial and later phase. Moreover, as  
246 demonstrated by the various differences between the four groups with different effects on CRP, IL-6  
247 and ferritin, subgroup specific diagnostics and therapy has to be performed.

248 We have to keep in mind that monoclonal antibodies (mAb) against SARS-CoV-2 react very specifically,  
249 the magnitude of neutralization reduction varied greatly among mAb, and there is evolution of  
250 resistance to mAbs by SARS-CoV-2 by epitope single amino acid substitutions in the spike protein (33).  
251 Thus, the results of the present study cannot be generalized to other CoV-2 variants without  
252 investigations performed with these CoV-2 strains.

253

254

255

## 256 **Conclusions**

257 In conclusion, in critically ill COVID-19 patients within the initial and hyperinflammation phase, effects  
258 of casirivimab and / or tocilizumab on endpoints mortality, infection and inflammation markers differ.  
259 It is supposed that application of specific monoclonal antibodies against the CoV-2 virus will have  
260 beneficial effects in the initial phase lowering viral load and transmission into deleterious  
261 hyperinflammation. In the hyperinflammatory phase, we might have to be cautious with long lasting  
262 inhibitory effects of IL-6 receptor blockade.

263

## 264 **Abbreviations**

265 C: casirivimab / imdevimab; 95% CI: 95% confidence interval; CoV-2: corona virus 2; C + T: casirivimab  
266 / imdevimab plus tocilizumab; CRP: C reactive protein; ECMO: extracorporeal membrane  
267 oxygenation; IL-6: interleukin 6; IL-6R: interleukin 6 receptor; LOS: length of stay; N: no casirivimab /  
268 imdevimab and no tocilizumab; NonSu: nonsurvivors; n. s.: not significant; Su: survivors; PCT:  
269 procalcitonin; T: tocilizumab; WHO: World Health Organization.

270

## 271 **Acknowledgements**

272 We wish to thank all physicians and nurses participating in the management of patients.

273

## 274 **Authors' contributions**

275 MW, NM, AO and KT contributed to the conception and design of the study. AO, NM, KT and MW  
276 generated, collected and assembled the data. Data analysis and interpretation: MW and NM analyzed  
277 and interpreted the data and drafted the manuscript. All authors read and approved the final  
278 manuscript.

279

280

281 **Funding**

282 There was no financial support for this study. None of the authors received any support by a  
283 pharmaceutical company or other agency.

284

285 **Availability of data and materials**

286 All data generated or analysed during this study are included in this published article. The datasets  
287 used and/or analysed during the current study are available from the corresponding author on  
288 reasonable request.

289

290 **Ethics approval and consent to participate**

291 Ethics approval has been given by the ethics commssion of the university Ulm, application nr. 129/22;  
292 NCT 06233357. Due to the fact, that clinical and laboratory data were gathered in routine care, no  
293 additional blood has been drawn, no diagnostic and no intervention in addition had been performed,  
294 the ethic's committe waived informed consent.

295

296 **Consent for publication**

297 Not applicable.

298

299 **Competing interests**

300 The authors declare that they have no competing interests.

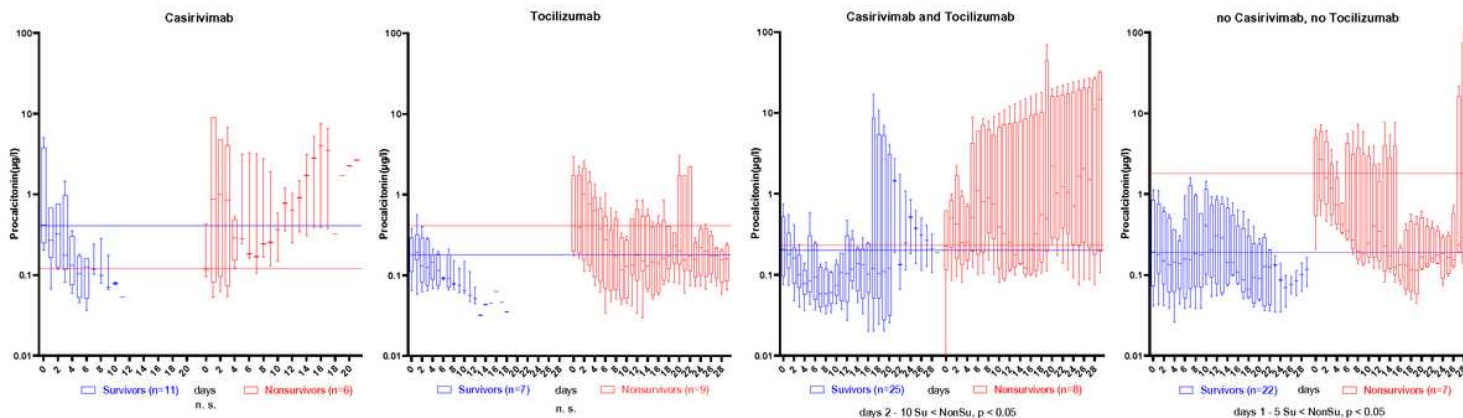

Fig. 4 PCT

## Figure 4

Time course of procalcitonin (PCT) serum concentrations in survivors and nonsurvivors of COVID-19 patients treated without (N) or with casirivimab / imdevimab (C) or tocilizumab (T), solely, or in combination of both (C + T). Comparison of days 1 – 30 with day 0. The blue line represents the median value of the survivors and the red line of the nonsurvivors at day 0. Note that procalcitonin values are given on a logarithmic scale. Mann-Whitney U-test for comparison of survivors and nonsurvivors, n. s.: not significant, Su: survivors, NonSu: nonsurvivors, \*p < 0.05

Fig. 5 CRP

## Figure 5

Time course of C-reactive protein (CRP) serum concentrations in survivors and nonsurvivors of COVID-19 patients treated without (N) or with casirivimab / imdevimab (C) or tocilizumab (T), solely, or in combination of both (C + T). Comparison of days 1 – 30 with day 0. The blue line represents the median value of the survivors and the red line of the nonsurvivors at day 0. Mann-Whitney U-test for comparison of survivors and nonsurvivors, n. s.: not significant, Su: survivors, NonSu: nonsurvivors, \* $p < 0.05$

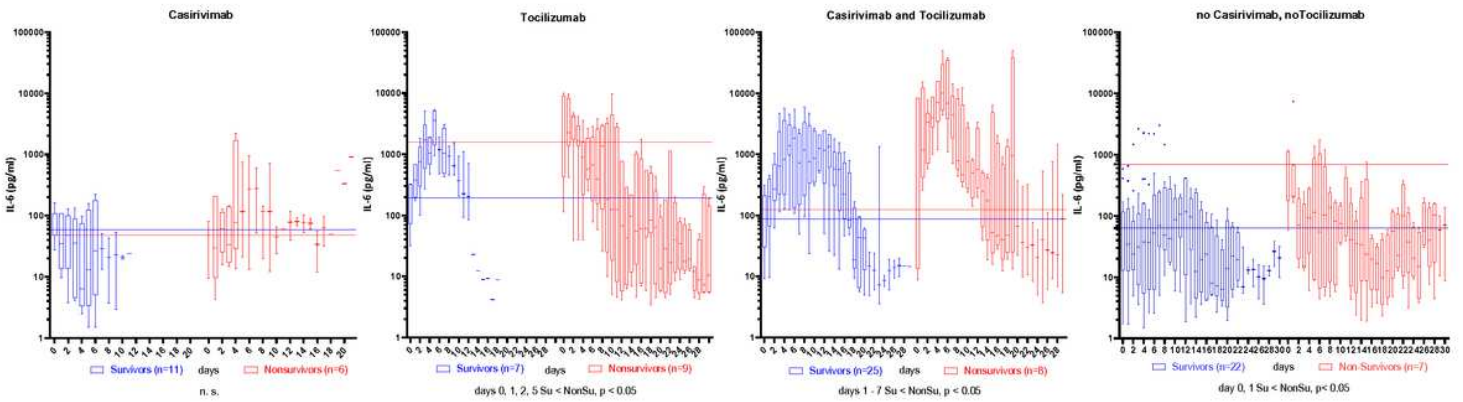

Fig. 6 IL-6

## Figure 6

Time course of interleukin 6 (IL-6) serum concentrations in survivors and nonsurvivors of COVID-19 patients treated without (N) or with casirivimab / imdevimab (C) or tocilizumab (T), solely, or in combination of both (C + T). Comparison of days 1 – 30 with day 0. The blue line represents the median value of the survivors and the red line of the nonsurvivors at day 0. Note that IL-6 values are given on a logarithmic scale. Mann-Whitney U-test for comparison of survivors and nonsurvivors n. s.: not significant, Su: survivors, NonSu: nonsurvivors, \* $p < 0.05$

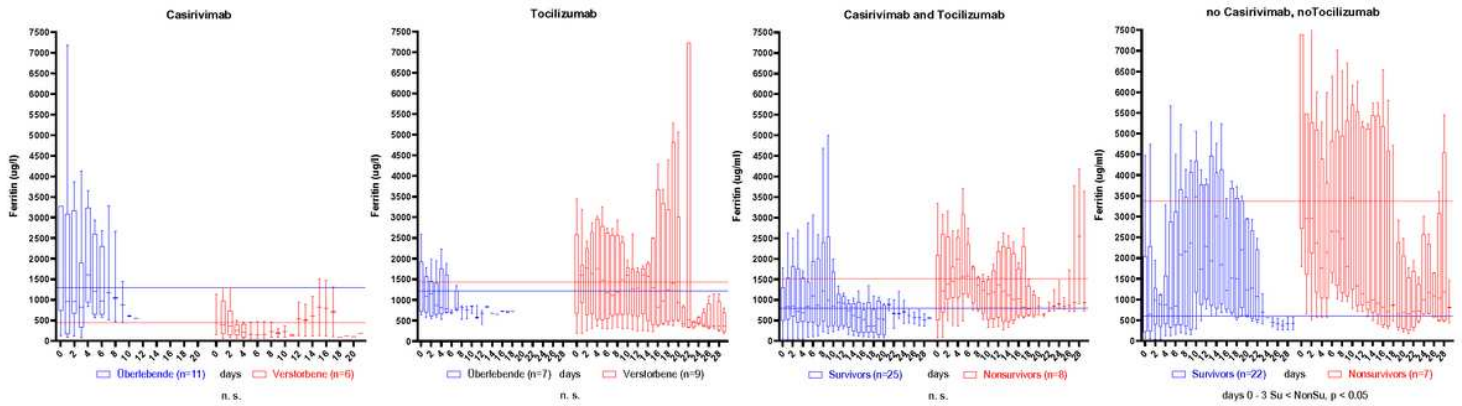

Fig. 7 Ferritin

## Figure 7

Time course of ferritin serum concentrations in survivors and nonsurvivors of COVID-19 patients treated without (N) or with casirivimab / imdevimab (C) or tocilizumab (T), solely, or in combination of both (C + T). Comparison of days 1 – 30 with day 0. The blue line represents the median value of the survivors and the red line of the nonsurvivors at day 0. Mann-Whitney U-test for comparison of survivors and nonsurvivors, n. s.: not significant, Su: survivors, NonSu: nonsurvivors, \*p < 0.05
