ABSTRACT

Although the relevant properties of the bismuthinite Bi_2S_3 , it was recently approved that the substitution of Se atoms in the Bi_2S_3 lattice can significantly enhance its electro-optical properties. In the present work, a detailed study on the structural, electronic and optical properties of $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ has been carried out based on first principle calculations. The simultaneous effect of Se-doping and spin-orbit coupling (SOC) on bismuth sulfide Bi_2S_3 was investigated. Our calculations show that $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ exhibits a narrow direct band gap of 1.062 eV after inclusion of the (SOC). The calculation of the carrier effective masses indicates that $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ may possess a high electron mobility material which is in accordance with experimental studies. The linear absorption optical spectra for both Bi_2S_3 and $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ show that doping bismuthinite with (Se) increases the optical absorption coefficient in the visible range and takes a value up to $10 \cdot 10^5 \text{ cm}^{-1}$. In addition, the dielectric function, optical conductivity and the energy loss function of Bi_2S_3 and $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ were also derived. The addition of the (Se) content induces a red shift in agreement with experimental studies. A noticeable effect of the (SOC) on the linear optical parameters was observed. The stability of the excitons was also studied by the estimation of the binding energy value. The dispersion energy parameters of Bi_2S_3 and $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ were estimated using a single oscillator model. Some nonlinearities have been computed with and without inclusion of (SOC) showing that $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ with large nonlinear optical parameters is promising candidate in photonic switching applications.

Keywords: Electronic structure, Optical properties, Spin-orbit coupling, Bismuth sulfide

1. Introduction

Bismuth chalcogenide materials Bi_2X_3 ($\text{X} = \text{S}, \text{Se}, \text{Te}$) are considered as the second generation topological insulators as they have insulating bulk band gap and conducting states on their surface [1]. Their bulk band gaps are generated because of the inherent spin-orbit coupling in these systems. The cation Bi^{3+} has a large relativistic effect and a strong sp hybridization in the valence band [2]. As a result, the Bi based materials may possess low carrier effective masses and therefore high carrier mobility leading them to be very useful in photovoltaic applications as a solar cell. Particularly, VI- bismuth materials Bi_2X_3 are functional compounds [3] and very attractive materials for several applications including: photovoltaics [4], thermoelectrics [5], photo-electrochemicals [6], photocatalytic activity [7], micro- and optoelectronic devices [8] and infrared detectors [9]. Among Bi_2X_3 materials, the bismuth sulfide Bi_2S_3 –bismuthinite- is a metal chalcogenide with a very attractive and intriguing properties : a large optical absorption coefficient ($> 10^5 \text{cm}^{-1}$ for $\lambda < 500 \text{nm}$), high electron mobility ($> 500 \text{cm V}^{-1}\text{s}^{-1}$) [10] and so on. The band gap of Bi_2S_3 is around 1.3-1.7 eV [11] and therefore lies in the visible light spectrum allowing it to be a light-absorber material in solar cells [12]. These relevant properties have allowed Bi_2S_3 to be a potential candidate for diverse domains such as photovoltaics [13], thermoelectrics [14], electrochemical hydrogen storage [15], lithium and sodium batteries [16], electrochemical sensors [17], X-ray computed tomography [18], and so on. Despite its interesting and relevant properties, the use of Bi_2S_3 in the various fields mentioned above is hampered by its large electrical resistivity [19] if it is used as the electron acceptor and its short lifetime of minority carriers if it is used in solar cells. To improve the efficiency of Bi_2S_3 in solar cells development and to enhance its electrical transport properties, a systematic study on intrinsic and extrinsic defects is crucial to optimize performances of bismuth sulfide Bi_2S_3 . Several researches have carried out a comprehensive study on intrinsic defects and doping in Bi_2S_3 . For example, H. Mizoguchi et al. [20] found that S vacancies in the lattice of bismuthinite can reduced its electrical resistivity by 2-3 orders of magnitude. Similarly, doping Bi_2S_3 by substitutional extrinsic elements such as Cl [21], Sb [22], Cu [23], Ag [24], Eu [25] and Mn [26] has been found to optimizing its carrier concentration so improving its electrical properties. Recently, much experimental reports have shown that the introducing selenium atoms to Bi_2S_3 can be considered as a very efficient way to increase its electrical and optoelectronic properties. It has shown that Se alloying bismuthinite in S sites ($\text{Bi}_2\text{S}_{2.85}\text{Se}_{0.15}$) could increase a figure of merit (ZT) and enhance the thermal conductivity

upon Se incorporation [19]. Ajara et al. [10] found that ($Bi_2S_{3-x}Se_x$) solid solutions possess interesting and attractive electrical properties than Bi_2S_3 . Recently, experimental investigations conducted by Ye Chen & al. [27] found that the power factor in the case of Se alloying at S sites in Bi_2S_3 is about 100 times larger than that of undoped Bi_2S_3 . $Bi_2S_{3-x}Se_x$ can be also an all-optical photonics switching device due to its interesting non-linear optical properties [28]. Photocatalytic activity can be highly increased when doping selenium into Bi_2S_3 photocatalyst [29]. It has also been proved that Se-doped Bi_2S_3 can be used as anodes for sodium-ion batteries [30]. In contrast, to our knowledge no theoretical study has been reported to date to investigate changes in electro-optical properties caused by the substitution of Se atoms into Bi_2S_3 . For this purpose, our study is focused on predicting the structural, electronic and optical properties of $Bi_2S_{3-x}Se_x$ ($x = 0$ and 0.25). The calculations were carried out using *ab initio* density functional theory (DFT) employing the Full-Potential Linearized Plane Wave (FP-LAPW) method. In the present paper we also discussed the effect of the spin-orbit coupling (SOC) on the electro-optical properties for Bi_2S_3 and the ternary bismuth sulfide $Bi_2S_{2.75}Se_{0.25}$.

2. Computational details

In the present study, the full potential linearized plane wave (FP-LAPW) method [31] as implemented in the Ab-initio simulation Wien2k [32] package based on the density functional theory (DFT) [33], is used to carried out all of the calculations. Perdew-Burke-Ernzerhof (PBE-GGA) scheme was used to describe the exchange-correlation interaction [34] in addition of spin-orbit coupling (SOC) [35]. In this study, the valence electrons are: $[6s^2 6p^3]$, $[3s^2 3p^4]$ and $[4s^2 4p^4]$ for Bi, S and Se atoms respectively. The potential and charge density inside the atomic spheres are taken by $l_{max} = 10$. The plane wave cut-off is fixed at $R_{MT} * K_{max} = 8$, where R_{MT} denotes the smallest muffin-tin radii of all atomic spheres and K_{max} is the largest k-vector of the reciprocal lattice. $G_{max} = 12$ (Ryd) $^{1/2}$ is truncated to develop charge density and the plane wave potential. The energy cut-off for separation core and valence electrons is set to -10 Ry. A 500 k-point are used in the irreducible Brillouin zone. A denser k-mesh are used for calculation of the optical properties. The calculations are self-consistently converged when the total energy convergence is fixed to be 10^{-4} Ry.

3. Results and discussion

3.1. Structural properties

Bismuthinite Bi_2S_3 crystallizes in orthorhombic structure with the space group $pbnm$ (62) [36]. There are four formula units per unit cell giving rise to 20 atoms in the primitive cell. The crystal structure of Bi_2S_3 consists of five non-equivalent atoms: two non-equivalent Bi sites and three non-equivalent S sites. Each Bi atom is linked to seven atoms of S. Three atoms of S are linked to Bi atom by short distances and the other four atoms of S are linked to Bi by long distances. The Bi-S short-bonds formed a strongly bonded ribbons while the Bi-S long-bonds formed a Van der Waals force introducing a weak interaction between the aligned ribbons [37]. To model the $Bi_2S_{3-x}Se_x$ structure, a $2 \times 2 \times 1$ supercell was constructed generating eight Bi atoms and twelve S atoms in unit cell with formula Bi_8S_{12} in which three S atoms were replaced by three Se atoms to get $Bi_2S_{2.75}Se_{0.25}$. The crystal structures of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are shown in Fig. 1.

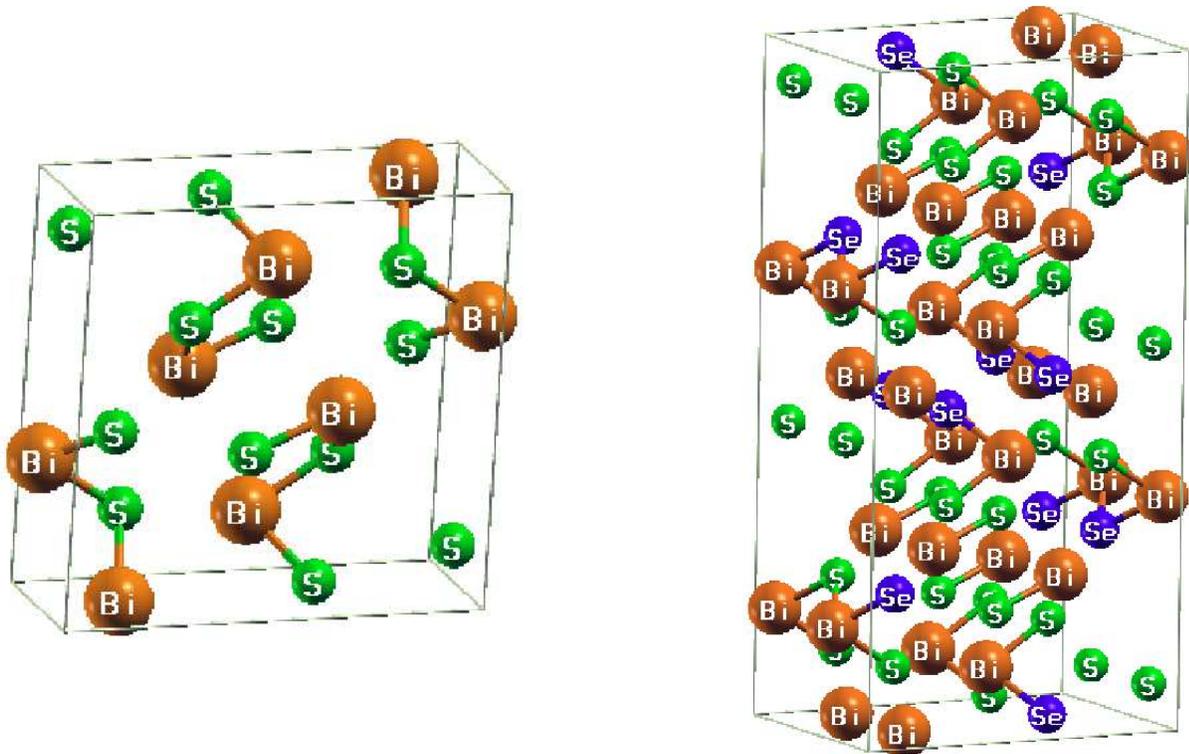

Fig. 1. The orthorhombic crystal structures of $Bi_2S_{3-x}Se_x$. (The left is the structure for $x = 0$ and the right for $x = 0.25$).

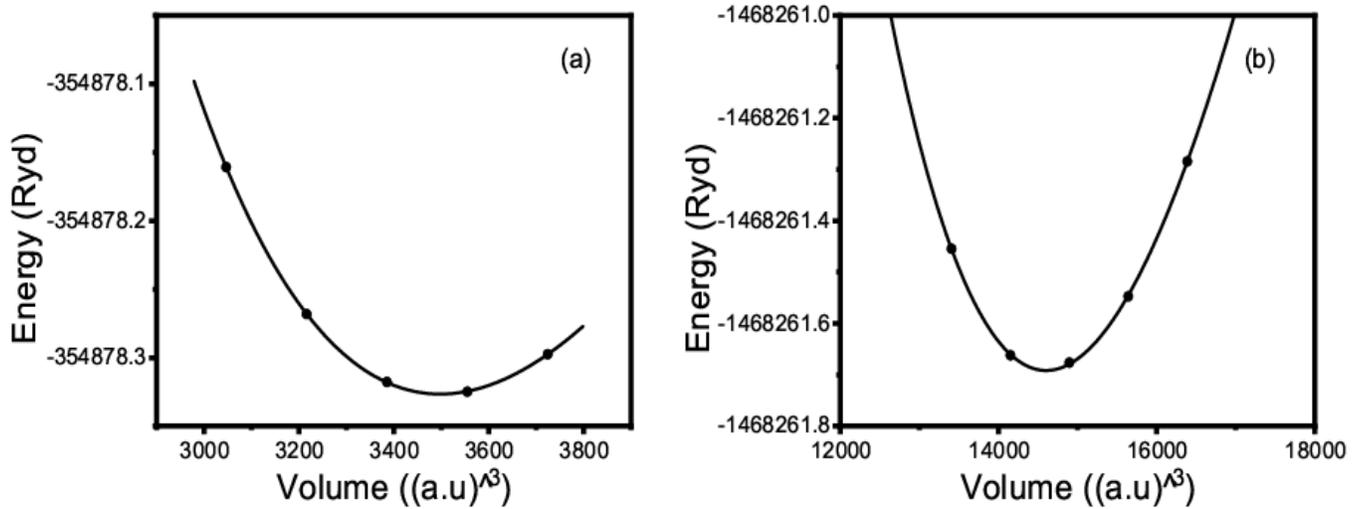

Fig. 2. Calculated total energy as a function of volume within GGA-PBE for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$.

To find the ground state properties of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$, the variation of the total energies as a function of volume is computed within the GGA-PBE method for different volumes about the equilibrium cell volume V_0 , using the Murnaghan's equation of state [38] as demonstrated in Fig.2. The calculated equilibrium lattice constants, the bulk modulus (B) and its derivative of pressure (B') for both compounds are given in Table1, with other previous theoretical and experimental results. From Table1, we see that the optimized lattice parameters for bismutinite Bi_2S_3 are in good agreement with theoretical results and slightly higher than the experimental data since the GGA approximation overestimates the lattice constants. In addition, the lattice constants increase with adding Se in the Bi_2S_3 lattice which can be explained by ionic radii difference between S^{2-} (1.81Å) and Se^{2-} (1.98Å).

Table1 Optimized lattice constants, bulk modulus B and its pressure derived B' and other available experimental data and theoretical values for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$.

3.2 Electronic properties

3.2.1 Electronic band structure

Based on the optimized lattice parameters, the electronic band structures of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ were evaluated using GGA-PBE approach with and without spin-orbit coupling (SOC). Fig. 3 (a-d) show the electronic band structures plotted along the high symmetry directions for the two structures Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$. For Bi_2S_3 , Fig.3a shows an indirect band gap with the valence band maxima (VBM) occurs at the X-point whereas the conduction band minima (CBM) is located along the G-Z direction. The calculated band gap of bismuthinite Bi_2S_3 at the PBE level is $E_g^{PBE} = 1.492$ eV which is in accordance with other theoretical and experimental results suggesting that Bi_2S_3 is an indirect band gap semiconductor ranging from 1.3-1.7 eV [11]. It is well-known that the inclusion of the SOC effect modify the electronic properties of the materials which contain heavy elements. In our case, with the spin-orbit effect consideration, the band gap of Bi_2S_3 decreases from $E_g^{PBE} = 1.492$ eV to $E_g^{PBE+SOC} = 1.208$ eV. $E_g^{PBE+SOC}$ is also an indirect band gap with (VBM) and (CBM) are located at Z-point and GY- path respectively, which is very close to the experimental value of 1.26 eV [27]. The computed energy band gaps of Bi_2S_3 at PBE and PBE+SOC levels are summarized in Table2 within previously theoretical and

experimental studies. Fig. 3(c-d) shows the electronic band structures of $Bi_2S_{2.75}Se_{0.25}$ with and without (SOC). Both band structures present a direct band gaps of $E_g^{PBE} = 1.34 eV$ and $E_g^{PBE+SOC} = 1.062 eV$ at PBE and PBE+SOC level respectively at Z point. The incorporation of Se atoms in the Bi_2S_3 lattice allowed to obtain a narrow band gap leading to activate the intrinsic conduction electrons and subsequently to enhance the electrical transport properties of the undoped Bi_2S_3 material. The reduction of the band gap by introducing the Se atoms in Bi_2S_3 has been observed experimentally by studying the $Bi_2S_{3-x}Se_x$ ($x=0.06-0.75$) materials [39] in which the band gap passes from 1.35 eV to 1.12 eV. Due to the fact that the obtained gap is direct, the $Bi_2S_{2.75}Se_{0.25}$ is satisfactory in optoelectronics and also it can be considered as a light-absorber compound in solar cells due to its value that is close to the optimal value of this kind of materials [40]. The calculated band gaps $E_g^{PBE+SOC}$ for Bi_2S_3 and the ternary $Bi_2S_{2.75}Se_{0.25}$ indicate that the (SOC) induces a considerable reduction compared to the E_g^{PBE} which can be explained by the splitting states near the Fermi level.

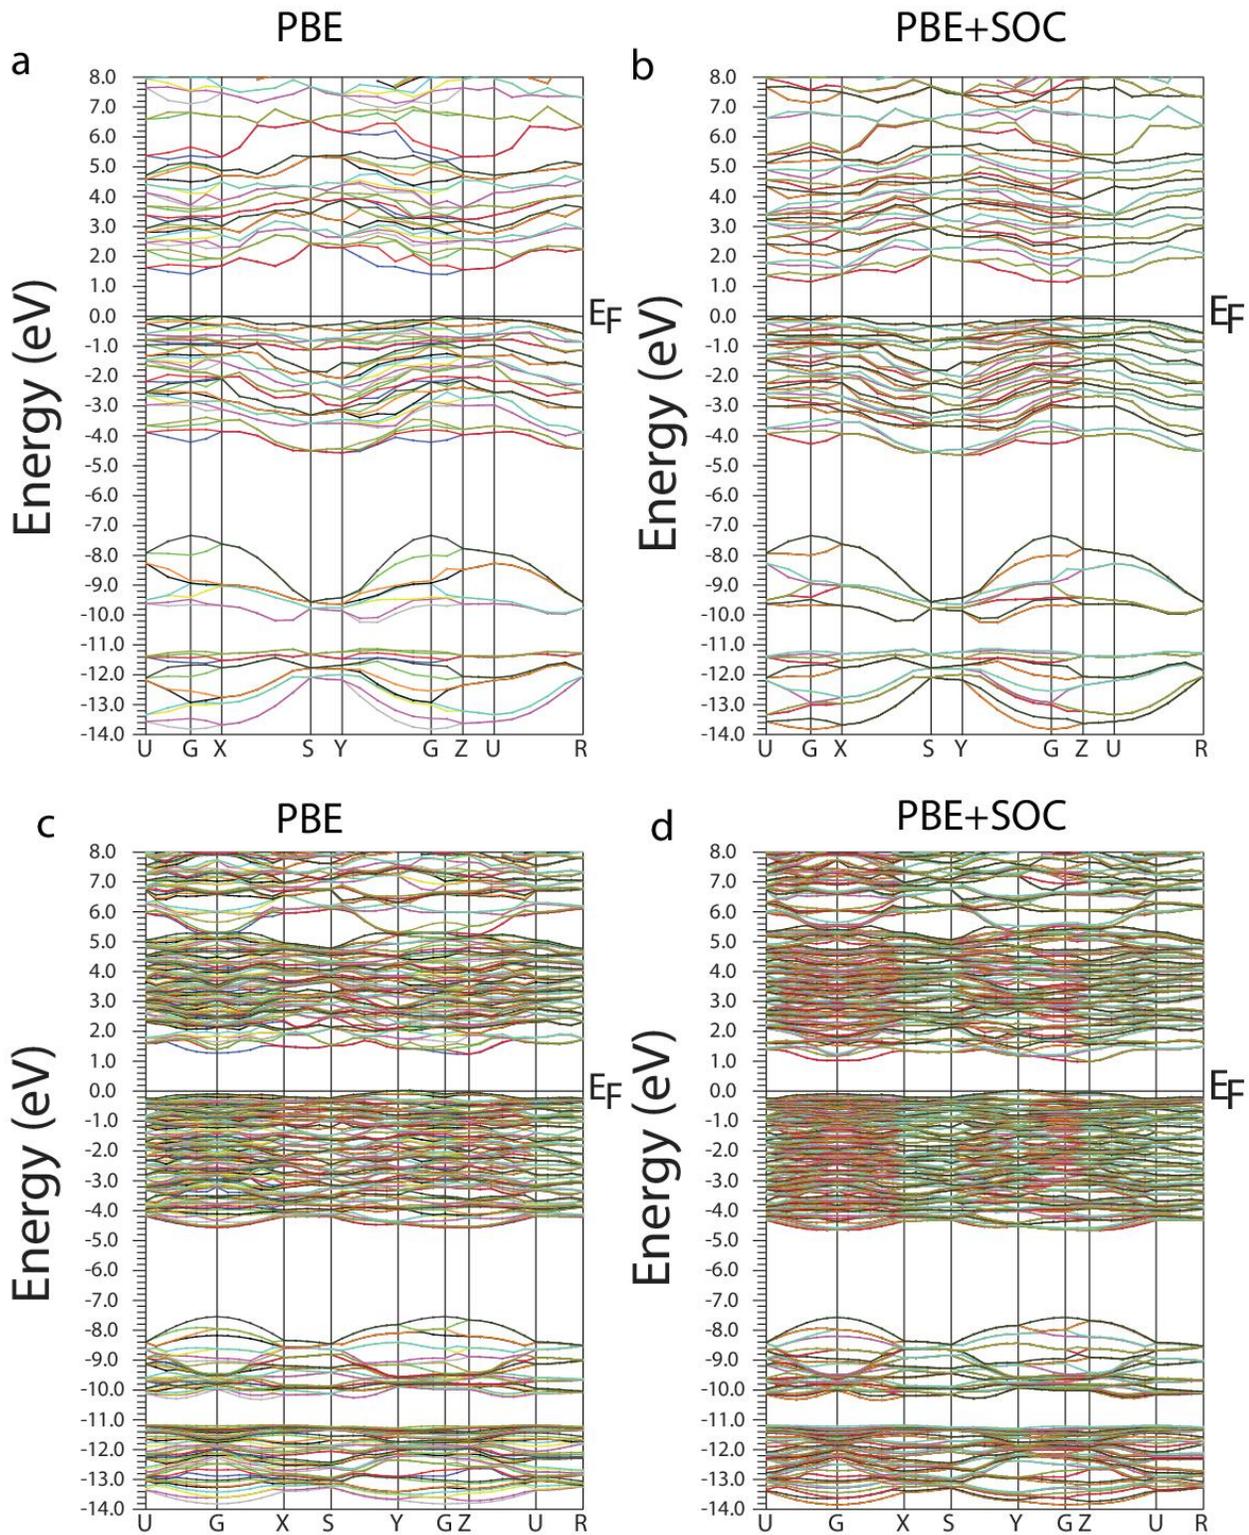

Fig. 3 Calculated electronic band structures of Bi_2S_3 (a,b) and $Bi_2S_{2.75}Se_{0.25}$ (c,d) with PBE and PBE+SOC methods.

Table 2 The calculated energy band gaps of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ with PBE and PBE+SOC methods with their corresponding theoretical and experimental data.

Compound	Method	E_g (eV)
Bi_2S_3	Present (GGA-PBE)	1.492
	Present (PBE-SOC)	1.208
	Theory (DFT-GGA and PAW) [41]	1.220
	Theory (LDA-PBE) [27]	
	Theory (PBE-SOC) [27]	1.380
	Experimental [27]	1.030
	Experimental [42]	1.260
$Bi_2S_{2.75}Se_{0.25}$		1.360
	Present (GGA-PBE)	1.340
	Present (PBE-SOC)	1.062

3.2.2 Density of states

The total density of states (TDOS) and the partial density (PDOS) for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ were calculated to unveil the atom orbital contribution to the band structure. (TDOS) and (PDOS) are calculated with and without (SOC) and are presented in Fig. 4 and Fig. 5. In these figures, the zero energy level is attributed to the Fermi level (E_f). It emerges from Fig. 4 that the lower part of the valence band is dominated by the Bi-6s and S-3s states. The 3p orbitals of S atoms have highly contribution to the upper valence band showing hybridization with Bi-6sp orbitals with a weak presence of Bi-5d states. The conduction band minimum is composed principally of the Bi-6p and S-3p characters. The same orbital contributions to the energy bands of $Bi_2S_{2.75}Se_{0.25}$ are observed with the addition of the p states of Se atoms which has a considerable contribution in the valence band maximum giving rise to the hybridization with Bi-6p orbitals. The Se 4p states contribute also in the conduction band minimum besides the p states of Bi and S atoms. After the inclusion of the (SOC), the contribution of the different states in the valence and the conduction

bands remains unchanged but a remarkable reduction in their densities is observed as shown in the Fig 4(d) and Fig 5(d) for the two materials. We find also that the bandwidth has increase by 0.112 eV for Bi_2S_3 and by 0.086 eV for $Bi_2S_{2.75}Se_{0.25}$ in the presence of (SOC). The obtained results from the electronic band structures as well as the density of states prove the influence of the introduction of the (SOC) on the electronic structure of the undoped and doped bismutinite Bi_2S_3 .

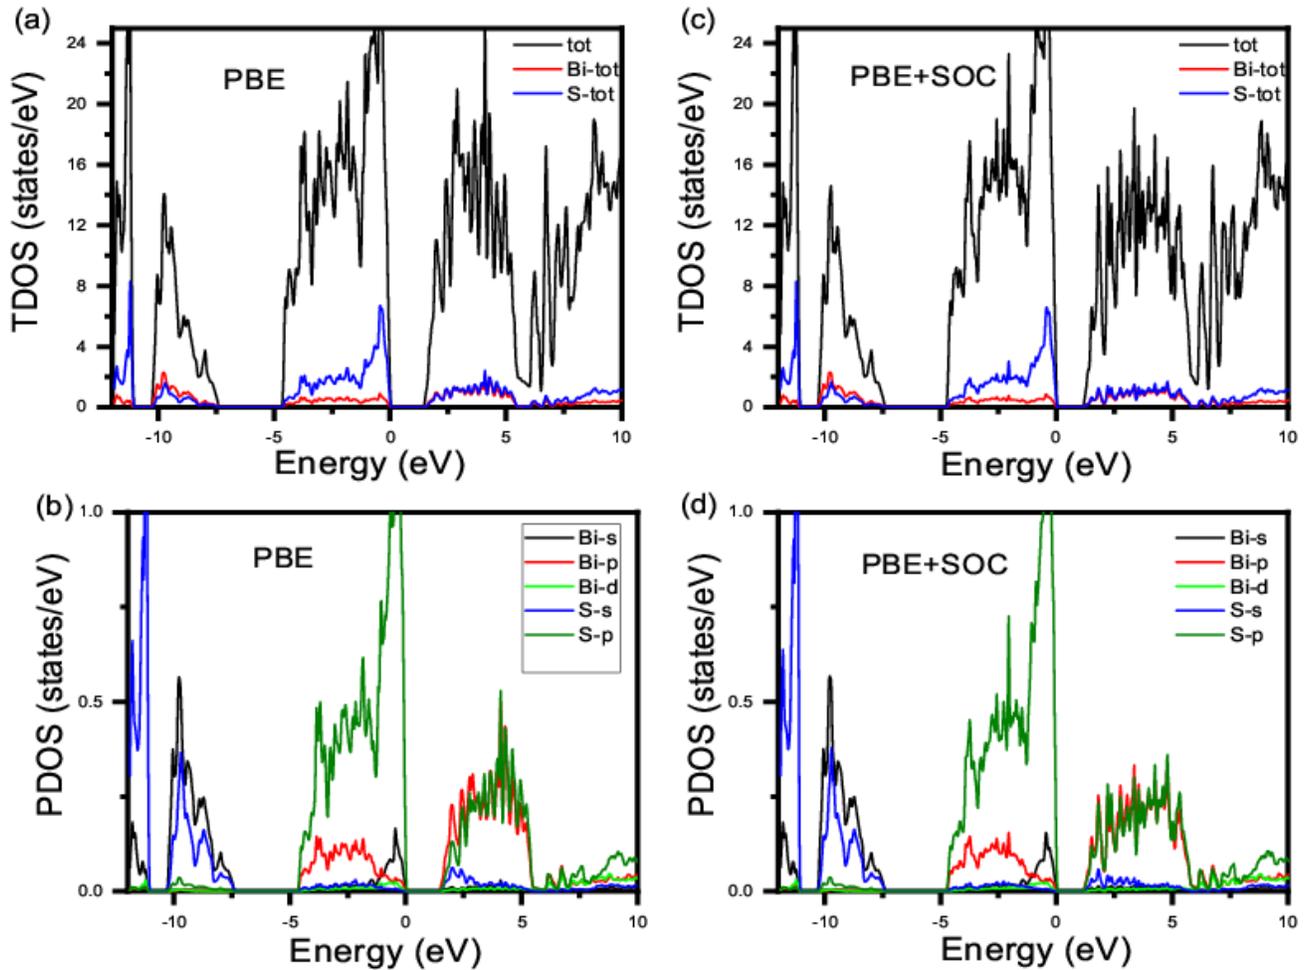

Fig. 4 Calculated total (TDOS) and partial density of states (PDOS) of Bi_2S_3 with PBE and PBE+SOC methods.

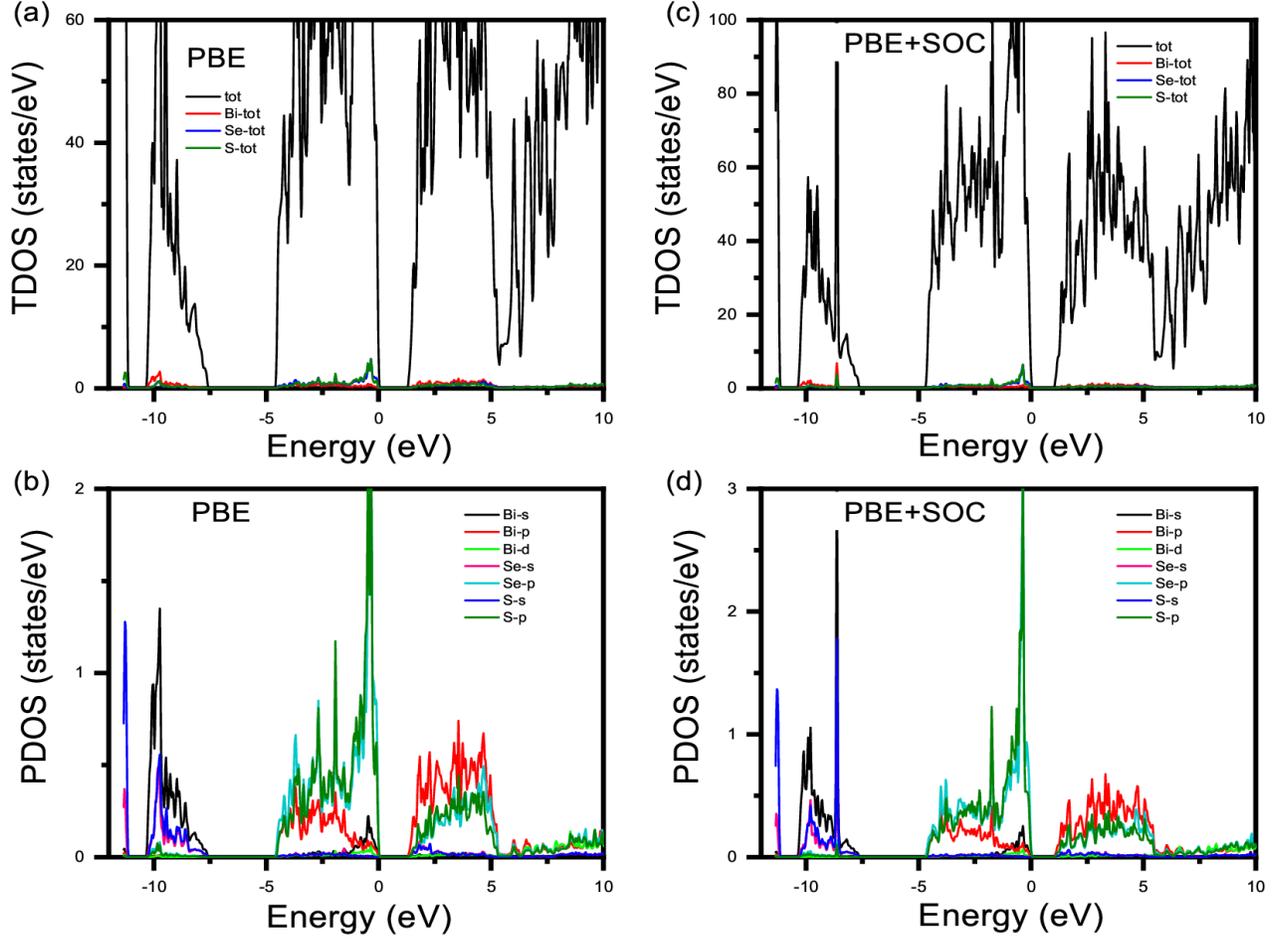

Fig. 5 Calculated total (TDOS) and partial density of states (PDOS) of $Bi_2S_{2.75}Se_{0.25}$ with PBE and PBE+SOC methods.

3. 2. 3 Effective masses

To understand the physical mechanism of the thermoelectric property of bismuthinite and the Se-doped bismuthinite (Bi_2S_3), carrier effective masses were calculated at G -point along G -Z (0,0,1/2) and G -X (1/2,0,0) directions in the first Brillouin zone of the $pbnm$ orthorhombic structure. For the calculation of the effective masses we use the approximation model given by [43] based on the calculated band structures with PBE+SOC model. The results are depicted in Table 3. As it is presented in Table 3, the electron effective masses m_e^* for both Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are smaller than the effective hole masses m_h^* , which is in accordance with the

experimental and theoretical studies [27, 41]. For Bi_2S_3 , our calculated average value of m_e^* is $1.85 m_0$ consistent with the previous experimental data [44] showing that m_e^* is ranging from 0.6 to $2.2 m_0$. The carrier effective mass anisotropy can be attributed to the anisotropic ratio $\frac{m_c^*}{m_a^*}$ where m_c^* and m_a^* are the carrier effective masses along the (G - Z) and (G - X) directions respectively. The calculated electron effective mass anisotropy is 1.30 for Bi_2S_3 and 2.42 for $Bi_2S_{2.75}Se_{0.25}$. The obtained higher anisotropy is related to the chemical bonds in the two crystals. The anisotropy increased when selenium atoms were substituted in Bi_2S_3 crystal resulting in a more covalent bonds along c-axis and a weaker ionic bonds along the a and b directions. In addition, the introduction of the Se atoms in bismuthinite crystal has the effect of reducing the electron and hole effective masses and thus an increase in the carrier mobility. This has been observed experimentally by Ajara et al. [28].

Table 3 Calculated effective masses of electrons and holes in units of free electron mass m_0 for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ along G - X and G - Z directions.

System	Direction	$m_e^*[m_0]$	$m_h^*[m_0]$
Bi_2S_3	G - Z	2.099	3.850
	G - X	1.607	4.530
$Bi_2S_{2.75}Se_{0.25}$	G - Z	0.489	1.301
	G - X	1.187	2.110

3. 3 Optical properties

3. 3. 1 Linear optical properties

The linear optical properties of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are calculated with and without (SOC) for radiation up to 12 eV as shown in Figs 6-10. All optical parameters are derived from the complex dielectric function $\epsilon(\omega) = \epsilon_1(\omega) + i\epsilon_2(\omega)$ which define the optical response of a medium at all photon energy. $\epsilon_1(\omega)$ is the real part of $\epsilon(\omega)$ corresponds to the dispersive behavior of the material while $\epsilon_2(\omega)$ is the imaginary part of $\epsilon(\omega)$ describing the absorptive behavior of

the medium [45]. As Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ crystallize in orthorhombic structure, the dielectric tensor $\epsilon(\omega)$ have three diagonal independent components ($\epsilon_{xx}, \epsilon_{yy}, \epsilon_{zz}$). In this paper, we have restricted our study of the optical properties for polarization parallel to the z direction ($E \parallel z$) which is considered as a preferential direction for enhancing electro-optical properties of Bi_2S_3 [46]. $\epsilon_1(\omega)$ spectra calculated with and without (SOC) for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ for ($E \parallel z$) are given by Fig. 6.

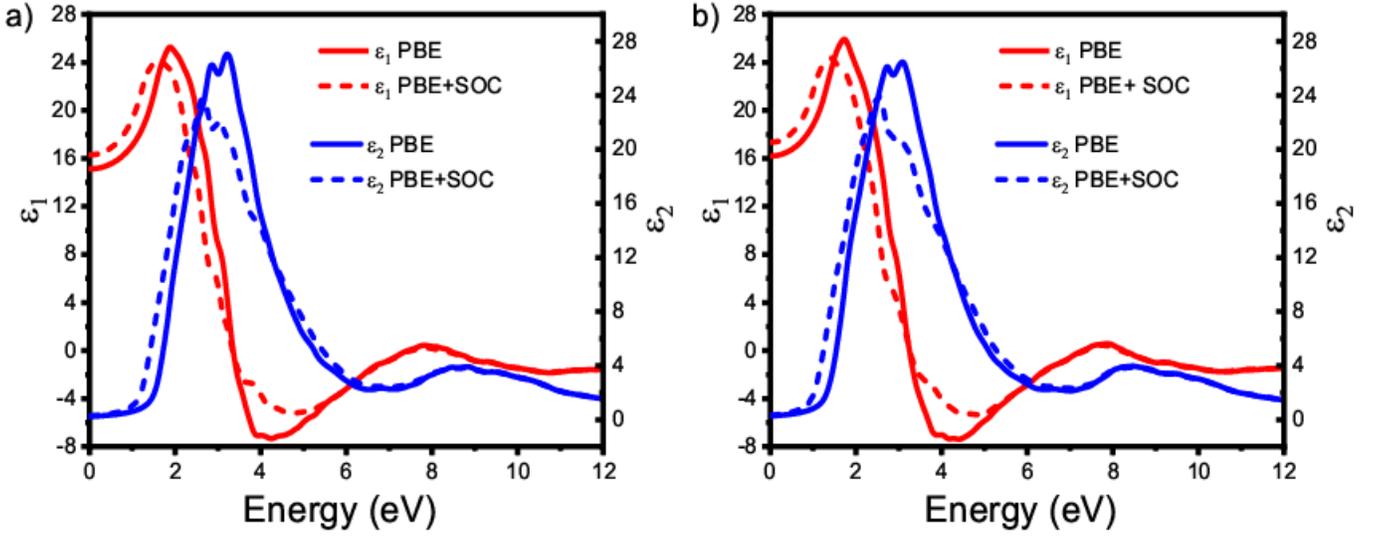

Fig. 6 Calculated real and imaginary parts of the dielectric function of Bi_2S_3 (a) and $Bi_2S_{2.75}Se_{0.25}$ with PBE and PBE+SOC method.

All $\epsilon_1(\omega)$ curves start from the static dielectric constant $\epsilon_1(0)$ which corresponds to the dielectric response at zero frequency. The static dielectric constants for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are listed in Table 4. It can be seen from Table 4 that $\epsilon_1(0)$ increased with the addition of the Se element and in the presence of the (SOC) giving rise to a high dielectric constant. To study the stability of the excitons, we calculate the exciton binding energy which can be calculated using the Bohr model [47],

$$E_b = \frac{13.6 \text{ eV} \cdot \mu^*}{\epsilon_\infty(0)^2} \quad (1)$$

where μ^* is the reduced mass given by : $\mu^* = \frac{m_e^* m_h^*}{(m_e^* + m_h^*)}$ and $\epsilon_\infty(0)$ is the static dielectric constant computed without (SOC) and listed in Table 4. To evaluate μ^* , we considered the directionally

averaged value for m_e^* and m_h^* given from the Table 3. Our calculated binding energy E_b for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are 74.16 meV and 29.10 meV respectively. The calculated values of E_b are in the same order of that of II-VI compounds [48]. The obtained results for E_b indicate that the incorporation of selenium (Se) atoms in the bismuthinite Bi_2S_3 decreases the exciton binding energy which induces a reduction in recombination, thus improving the efficiency of the extraction of the charge carriers.

Table 4 Calculated optical constants for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$: static dielectric constant $\epsilon_1(0)$, static refractive index $n(0)$, oscillator energy E_0 , dispersion energy E_d and oscillator strength \mathcal{F} calculated with and without SOC.

Compound	Method	$\epsilon_1(0)$	$n(0)$	$E_0(eV)$	$E_d(eV)$	$\mathcal{F}(eV^2)$
Bi_2S_3	Present (GGA-PBE)	14.981	3.886	2.866	40.429	115.869
	Present (PBE-SOC)	16.183	3.887	2.135	30.122	54.3100
$Bi_2S_{2.75}Se_{0.25}$	Present (GGA-PBE)	16.315	4.310	2.268	39.882	104.809
	Present (PBE-SOC)	17.375	4.157	2.214	36.061	79.8390

It can be seen from Fig. 6 (a-b), that $\epsilon_1(\omega)$ decrease to values below zero indicating that the reflection is maximum in the energy range about (3-7) eV and the materials exhibit metallic behavior in this area. The absorptive part $\epsilon_2(\omega)$ calculated with and without (SOC) for ($E \parallel z$) is illustrated in Fig. 6 (a-b) for both compounds. $\epsilon_2(\omega)$ spectra represent a pronounced peak located at 3.233 eV and 3.102 eV for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ respectively before the inclusion of the (SOC). With the inclusion of the (SOC), these high intensity peak of ϵ_2 show a red shift. A second peak, who is weaker than the first one, appears at 8.861 eV and 8.512 eV before and after inclusion of the (SOC) for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ respectively. Thus, these differences in the results of the dielectric constants confirm the crucial role of SOC effects in the optical properties of undoped and doped Bi_2S_3 . Our calculated maximum value of ϵ_2 for ($E \parallel z$) for Bi_2S_3 is in accordance with maximum peak values given theoretically by [49]. It is known that $\epsilon_2(\omega)$ is directly related to the

optical electron transition. From PDOS displayed in Figs. 4-5 and for both compounds, the transition between the occupied states Bi 6s to unoccupied states S 3p is at the origin of the appearance of the main peaks, while the second peaks originate from transition occurring between Bi 6s and S 3p electrons. For $Bi_2S_{2.75}Se_{0.25}$ there is another transition between Se 3p and Bi 6p states participating in the appearance of the main peak in $\epsilon_2(\omega)$.

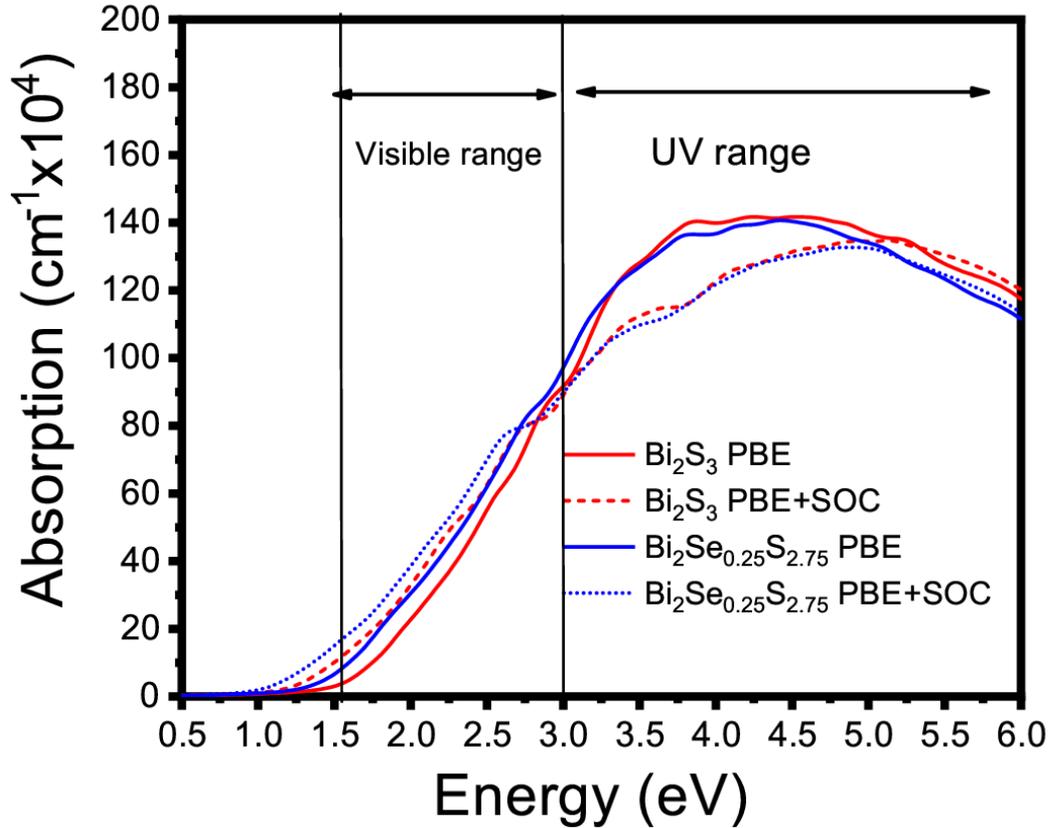

Fig. 7 Calculated absorption coefficient $\alpha(\omega)$ of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ with PBE and PBE+SOC methods.

The absorption coefficient $\alpha(\omega)$ spectra for ($E \parallel z$) calculated with and without (SOC) for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are given by Fig. 7. As can be seen from the $\alpha(\omega)$ spectra, the threshold of absorption is around 1.391 eV and 1.305 eV for undoped and doped Bi_2S_3 respectively. This shows

that there was a shift towards low energies on the absorption edge with the incorporation of the Se atoms. This confirms the experimental results carried out on $\text{Bi}_2\text{S}_{3-x}\text{Se}_x$ [27]. With the addition of (SOC), the threshold of absorption decrease and take the values of 1.192 eV and 1.010 eV for Bi_2S_3 and $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ respectively. The calculated energies of the threshold of absorption are close to the energy band gaps of Bi_2S_3 and $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ evaluated with and without the addition of (SOC) (see Table 2). In the energy range up to 3 eV, the absorption is maximum for $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ has a value of $94.793 \times 10^4 \text{ cm}^{-1}$, while at the same energy the undoped bismuthinite present an absorption of the order of $90.228 \times 10^4 \text{ cm}^{-1}$ in agreement with the experimental values ($104 - 105 \times 10^4 \text{ cm}^{-1}$) [10]. This clearly shows that Bi_2S_3 becomes more absorbent in the visible range by doping it with selenium. For higher energy extending up to 3 eV, Bi_2S_3 crystal has a higher absorption than that of $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$. The calculated high absorption coefficient of the ternary $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ shows that it is a very promising material in photovoltaic applications. The addition of the (SOC) acts strongly on the absorption spectra particularly in the visible range where a slight shift is observed for both compounds. The optical conductivity $\sigma(\omega)$ describes the electron conduction produced by an incident photon crossing a material. The optical conductivity spectra for (E||z) calculated with and without addition of the (SOC) for both compounds are presented in Fig. 8. The optical conductivity presents a sharp peak in the visible range for both compounds Bi_2S_3 and $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$. The maximum value of the optical conductivity decrease in the case of the calculation with (SOC) effect. $L(\omega)$ is the electron energy loss function describing the energy loss of a fast electron crossing a medium. The energy loss (Eloss) spectra for Bi_2S_3 and $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ calculated with and without (SOC) for (E||z) are given by Fig. 9. $L(\omega)$ present a prominent peak called the plasma resonance [50] located around 7.231 eV and 7.138 eV for Bi_2S_3 and $\text{Bi}_2\text{S}_{2.75}\text{Se}_{0.25}$ materials respectively. The corresponding plasma frequencies are $10.980 \times 10^{15} \text{ Hz}$ and $10.839 \times 10^{15} \text{ Hz}$. The calculated value of the plasma excitations for Bi_2S_3 is in accordance with theoretical results [49] and experimental measurements [51].

The refractive index $n(\omega)$ and the extinction coefficient $k(\omega)$ for (E || z) are plotted in the Fig. 10. It can be seen that $n(\omega)$ curves present an important value in low energy region and remarkable reduction in high energy region. To analyze the refractive index at lower optical frequencies one can use the Wemple - DiDomenico (WDD) single-oscillator model [52] which is the most applied

concept for the chalcogenide semiconductors. The (WDD) model is given by the following expression:

$$(n^2 - 1)^{-1} = \frac{E_0}{E_d} - \frac{1}{E_0 E_d} (h\nu)^2 \quad (2)$$

here, E_0 and E_d are the dispersion energy parameters, h is Planck's constant and $h\nu$ is the photon energy.

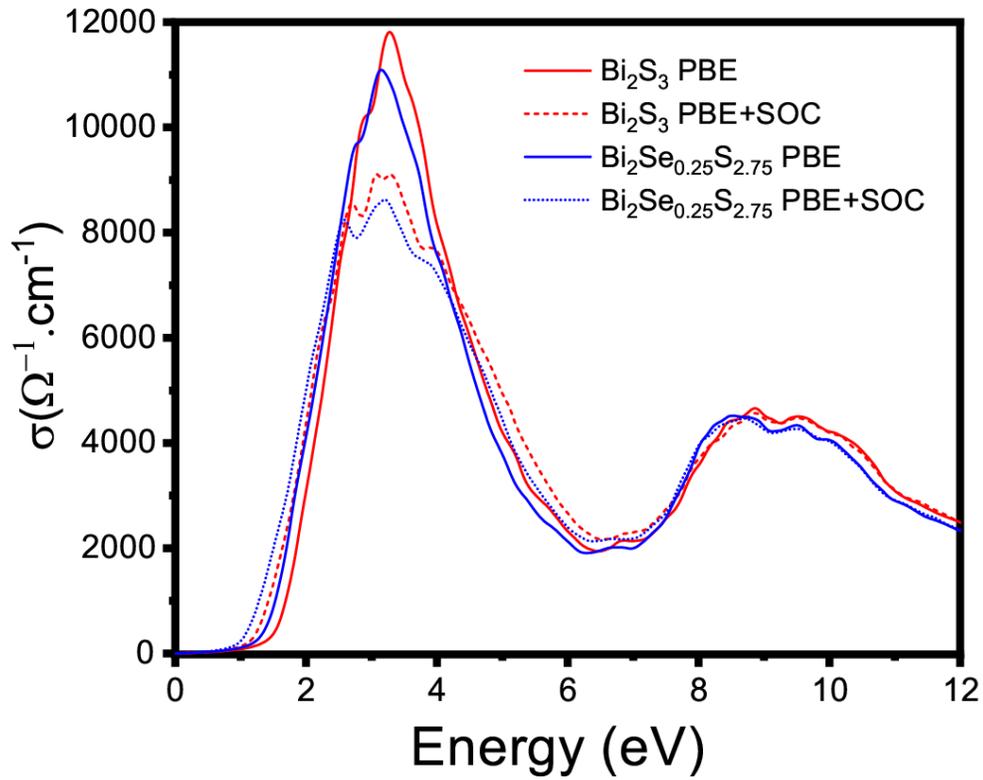

Fig. 8 Calculated optical conductivity $\sigma(\omega)$ of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ with PBE and PBE+SOC methods.

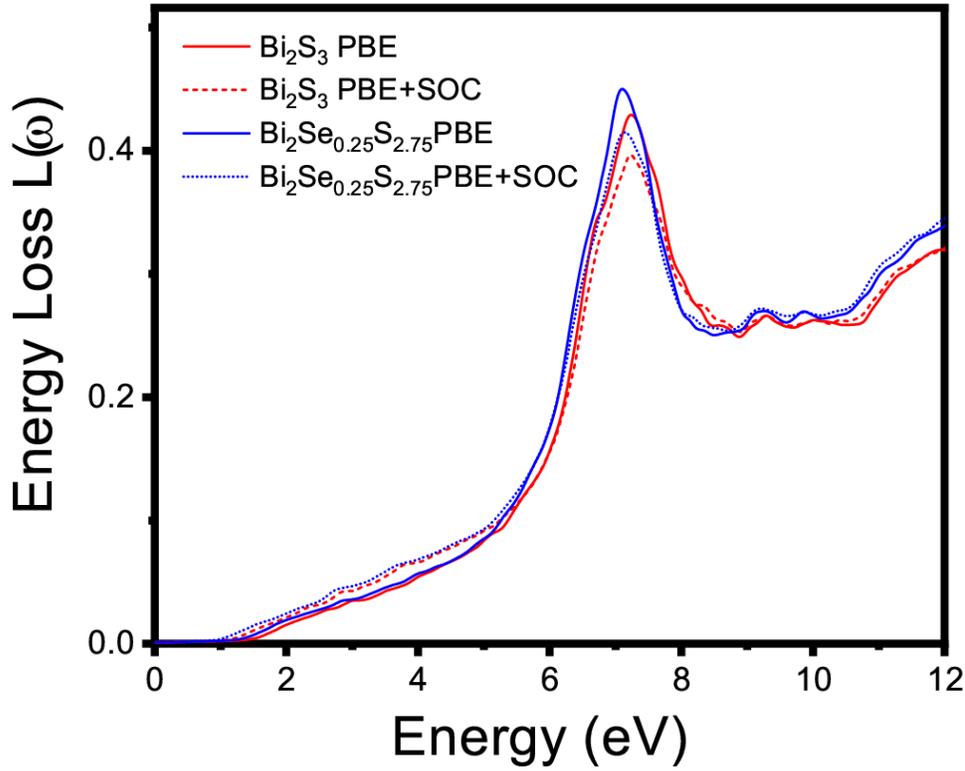

Fig. 9 Calculated energy loss function $L(\omega)$ of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ with PBE and PBE+SOC methods.

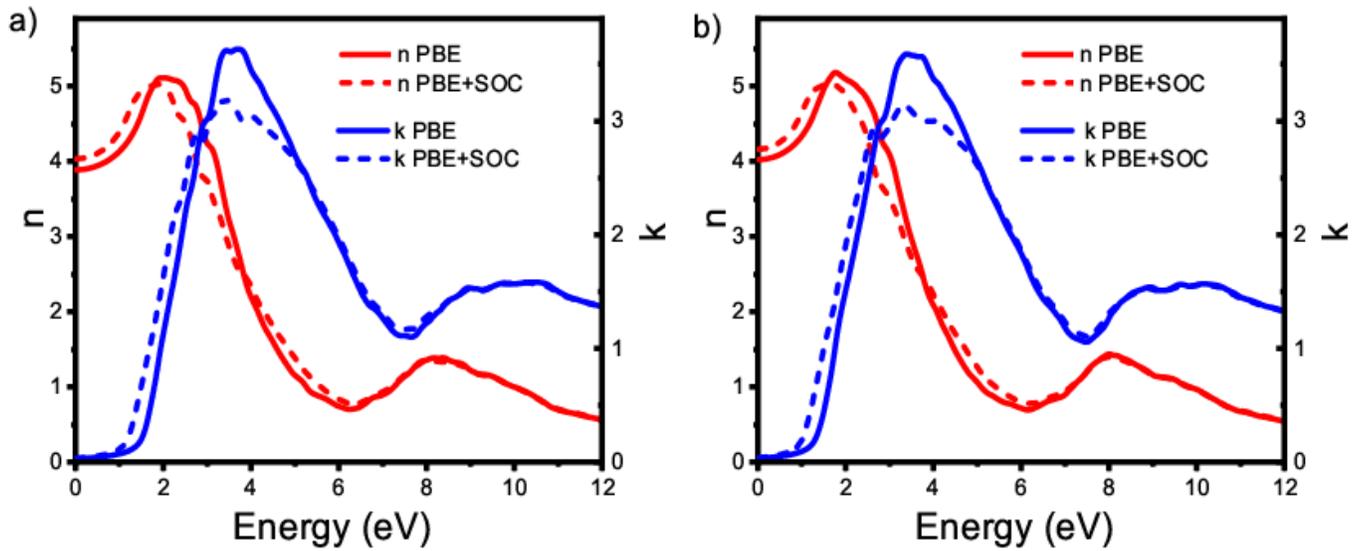

Fig. 10 Calculated complex refractive index $n(\omega)$ and extinction coefficient $k(\omega)$ of Bi_2S_3 (a) and $Bi_2S_{2.75}Se_{0.25}$ (b) with PBE and PBE+SOC methods.

The dispersion energy E_d corresponds to the dispersion of the electronic dielectric function related to the interband transition force, while E_0 is the single oscillator energy connected with the optical energy gap called WDD band gap [52]. The dispersion parameters for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ were estimated by fitting the plot $(n^2 - 1)^{-1}$ versus $(h\nu)^2$ in low energy region as shown in Fig. 11. Our calculated values of E_d and E_0 for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ calculated with and without (SOC) are listed in Table 4. From Table 4, the dispersion energy E_d decreased while passing from Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ after and before the inclusion of (SOC). This is essential due to the addition of the Se atoms in Bi_2S_3 lattice which induced a weak force of the interband transitions. Similarly, the oscillatory energy E_0 decreases for $Bi_2S_{2.75}Se_{0.25}$ due to the decrease in the energy band gap. Based on the (WDD) model, we can calculate the static refractive index $n(0)$ from equation: $n(0) = \sqrt{1 + \left(\frac{E_d}{E_0}\right)}$. The static refractive indexes $n(0)$ for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ calculated with and without (SOC) are given in Table 4. Another important parameter given by the WDD model is the oscillator strength given by : $\mathcal{F} = E_0 E_d$. The calculated values of \mathcal{F} for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are reported in Table 4.

3.3.2 Non-linear optical parameters

The optical non-linearity of materials is directly related to the control of the light in optical switching devices. In the present work, the nonlinear optical properties (NLO) were studied from the calculation of the 3rd order nonlinear optical susceptibility $\chi^{(3)}$ and the non-linear refractive index n_2 for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ within the Miller's rule and the static refractive index $n(0)$ [52]. It is known that the non-linearity occurs when the electromagnetic field becomes high enough. $\chi^{(3)}$ can be evaluated by the following expression:

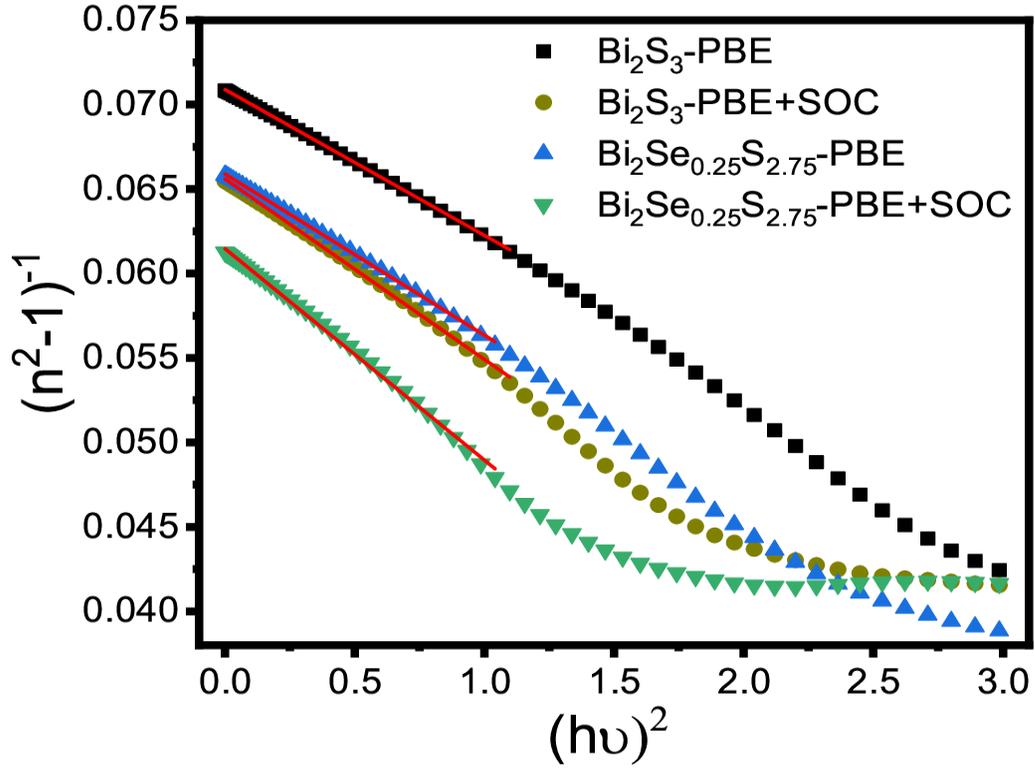

Fig. 11 $(n^2 - 1)^{-1}$ versus $(hv)^2$ for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ plotted with and without SOC

$$\chi^{(3)} = \frac{A}{(4\pi)^4} \left(\frac{E_d}{E_0} \right)^4 \quad (3)$$

where A is a constant independent of the frequency and equal to 1.7×10^{-10} esu [52], E_d and E_0 are the dispersion parameters given by the (WDD) single-oscillator model. The non-linear refractive index n_2 is related to $\chi^{(3)}$ and the static refractive index n_0 and given by :

$$n_2 = \frac{12\pi\chi^{(3)}}{n(0)} \quad (4)$$

The calculated values of $\chi^{(3)}$ and n_2 for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are summarized in Table 5.

Table 5 Non-linear optical parameters: third-order nonlinear optical susceptibility $\chi^{(3)}$ and nonlinear refractive index n_2 for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ calculated with and without (SOC).

Compound	Method	$\chi^{(3)} 10^{-10} esu$	$n_2 10^{-10} esu$
Bi_2S_3	Present (GGA-PBE)	2.699	4.363
	Present (PBE-SOC)	2.701	4.369
$Bi_2S_{2.75}Se_{0.25}$	Present (GGA-PBE)	6.512	9.493
	Present (PBE-SOC)	4.797	7.493

From Table 5, the calculated values of the (NLO) parameters $\chi^{(3)}$ and n_2 for Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are large and this can be related to the electronic and geometrical structure of these two materials. The obtained value of $\chi^{(3)}$ coefficient of the bulk Bi_2S_3 is larger than measured experimentally for Bi_2S_3 nanocrystal: $6.25 \times 10^{-11} esu$ [53]. This difference is due in particular to the quantum confinement effect in the nanocrystals. In addition, the results presented in Table 5 show that doping Bi_2S_3 with Se atoms further expanded the (NLO) coefficients $\chi^{(3)}$ and n_2 thus showing the effect of Se doping Bi_2S_3 in improving the nonlinear optical properties and consequently in the realization of a promising nonlinear optical materials.

4. Conclusion

The effect of spin orbit coupling on electronic and optical properties of $Bi_2S_{2.75}Se_{0.25}$ are investigated by means of Wien2k code based on the density functional theory. Firstly, the structural properties such as lattice constants, the bulk modulus and its pressure derivative of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ are calculated within the PBE-GGA scheme. The calculated electronic band structures show that $Bi_2S_{2.75}Se_{0.25}$ is a direct band gap semiconductor with and without the inclusion of (SOC). The energy band gap reduction with respect to that of undoped Bi_2S_3 is due

to the splitting states near the Fermi level when the (SOC) is taken into account. The carrier effective masses of Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ were calculated along high symmetry directions showing an increase in the anisotropy when Se atoms were incorporated and an increase in the carrier mobility. The linear optical properties of Bi_2S_3 and Se doped Bi_2S_3 (dielectric function, absorption, optical conductivity and energy loss function) were investigated for polarization parallel to the z axis. All linear optical spectra show a red shift when incorporating Se atoms in Bi_2S_3 lattice and after inclusion of (SOC). $Bi_2S_{2.75}Se_{0.25}$ exhibits a high absorption coefficient in the visible region showing its potential use in future for applications in solar cells. The static dielectric constant increase in $Bi_2S_{2.75}Se_{0.25}$ with (SOC) effect giving rise to a decrease in the exciton binding energy. The oscillator parameters : the oscillator energy, the dispersion energy and the static refractive index for both Bi_2S_3 and $Bi_2S_{2.75}Se_{0.25}$ materials were estimated using the (WDD) single-oscillator model. It was found that the inclusion of Se content in Bi_2S_3 leads to the increase of the static refractive index but a decrease in the oscillator parameters. The nonlinear optical properties (NLO) of doped and undoped Bi_2S_3 were also reported. A large values of (NLO) parameters were obtained for $Bi_2S_{2.75}Se_{0.25}$ indicating that it can be a useful device for all-optical communication and computer network. The present work constitutes a first theoretical report about the substitution of the selenium atoms for sulfur sites in Bi_2S_3 . We strongly believe that our study on the electronic, linear and nonlinear optical properties of the ternary bismuth sulfide $Bi_2S_{2.75}Se_{0.25}$ is important for the development of a new high-performance optoelectronic material in the Bi-based compounds.
