# Abstract

Background Q fever has been associated with perinatal complications. We conducted a prospective follow-up study to assess both the incidence of adverse pregnancy outcomes (APOs) associated with *Coxiella burnetii* infection and the contribution of Q fever to APOs. Methods Between May 1 and October 31, 2013, within the level-3 maternity of Saint Pierre hospital, Reunion island, we investigated unexplained miscarriages, stillbirths, preterm births or small-for-gestational age children. Seropositivity for *C. burnetii* antibodies was defined using indirect immunofluorescence for a phase 2 IgG titre  $\geq 1:64$ . Acute Q fever was defined for a phase 2 IgG titre  $\geq 1:256$  and/or the presence of IgM  $\geq 1:48$  or the detection of *C. burnetii* genome in miscarriage products and placentas. Incidence rate ratios (IRR) for Q fever related APOs (taken as a composite outcome or individually) were assessed using Poisson regression models for dichotomous outcomes controlling major confounders. Results Over a 6-month period, 179 pregnant women suspected or diagnosed with an APO were investigated for Q fever, of whom 118 met the definition for an APO. Of these, 19 were seropositive and 10 presented a profile indicative of an acute infection. For three women with an acute Q fever, the chronology between the onset of infection and the APO (2 miscarriages, 1 preterm birth) with respect to the kinetics of antibodies suggested causality in the pathogenesis. The incidence of Q fever related APOs was estimated between 2.2‰ and 5.2‰, whether causality was requested or not. Both *C. burnetii* exposure and acute Q fever were independently associated with APOs (IRR 1.55, 95% CI 1.31-1.84; IRR 1.47, 95% CI 1.15-1.89, respectively). Conclusions In the endemic context of Reunion island, acute Q fever may lead to APOs. To limit the burden of Q fever on reproduction, pregnant women should be kept away from farms and avoid direct contact with ruminants.

## Background

Q fever is a zoonosis of global public health importance that is caused by *Coxiella burnetii*, an obligate Gram negative intracellular bacterium, maintained in wildlife through mammals, birds and arthropods (*e.g.* ticks), serving as reservoirs [1]. Cattle, goats and sheep are the primary sources of human contamination [1,2]. These suffer various reproductive disorders, of which spontaneous abortion (miscarriage), preterm delivery, intrauterine growth restriction and foetal loss may represent an economic burden [1–3]. Human infection is usually acquired through inhalation of contaminated aerosols from infected animals that contaminate the environment through excretion of bacteria in large amounts in byproducts during childbirth, especially placentas [1].

In prospective observational studies of pregnant woman, Q fever has been associated inconsistently with miscarriage [3,4], preterm birth [5–7], or low birthweight [7], and infrequently with foetal death [8], or congenital malformations [8]. These adverse pregnancy outcomes (APOs) have been associated with both acute and persistent Q fever infections [9]. They are likely the consequence of detrimental placental immune cell responses overcoming the normal host proinflammatory trophoblast cell program, whilst the human trophoblast is believed to serve as niche for bacterial replication [10]. Notwithstanding, causal relationship between exposure to Q fever and APOs remains elusive given discrepancies between case series and observational studies.

Following the documentation of Q fever endocarditis [11], peaks of prematurity and unexplained foetal deaths in birth registries, and in the preparedness of a serosurvey among parturient women (*Jaubert et al., under review*), we conducted a prospective follow-up study to assess the cumulative incidence of APOs of unknown origin associated with *C. burnetii* infection. Our secondary objective was to evaluate the contribution of acute Q fever infection to APOs.

## Methods

### *Setting and population*

La Réunion is a small tropical island (2,512 km<sup>2</sup>), located in the South Western Indian ocean, 700 km east of Madagascar. Landscapes are very contrasted with a mountainous centre separating a humid “windward” east coast from a dry “leeward” west coast. The domestic animal populations comprised roughly 40,000 cattle, 30,000 goats and 2,000 sheep, mainly based in the West and the South microregions [2]. Coastal areas are the most densely populated and host approximately 80% of the 816,000 residents.

Between May 1 and October 31, 2013, all pregnant women presenting at the level-3 maternity of Saint Pierre hospital for an unexplained early (< 12 weeks) or late (12 to 21 weeks) miscarriage, stillbirth (intrauterine foetal death  $\geq 22$  weeks) preterm birth (PTB, <37 weeks) or small-for-gestational age child (SGA, birthweight <10<sup>th</sup> percentile), were proposed to add a Q fever workup in addition to the usual data collection of a birth registry [12,13]. Women were enrolled either prospectively, when the APO event was suspected (*e.g.*, preterm labour, poor growth of uterine height), or retrospectively, when the APO event had occurred.

### *Laboratory methods*

Sera were tested using an indirect fluorescent antibody (IFA) assay with commercially available antigens for *C. burnetii* (*C. burnetii* I+II IFA IgG/IgM/IgA<sup>®</sup>, Vircell, Grenade, Spain).

Seropositivity was defined for a phase 2 or phase 1 IgG titre  $\geq 1:64$  with or without phase 2/1 IgM  $\geq 1:48$ . Acute Q fever was defined for a phase 2 IgG titre  $\geq 1:256$  and/or the presence of phase 2 IgM  $\geq 1:48$  or detection of *C. burnetii* genome on miscarriage products and placentas. These thresholds were chosen conservative to fulfil the National Reference Centre requirements and minimize the false positives [14]. Persistent Q fever was defined for a phase 1 to phase 2 IgG ratio >1 in the absence of IgM antibodies [15]. Women were proposed serology follow-up to check for seroconversion (4-fold increase in titres between 2 paired samples) as done in standard care.

Bacterial DNA was searched within birth products by real-time polymerase chain reaction (PCR) amplification of the IS1111 region of the *C. burnetii* genome. Biological plausibility was defined by a positive RT-PCR or the seroconversion of phase 2 IgG. The relationship between exposure to Q fever and APOs was deemed causal when temporality and biological plausibility criteria were met.

## Statistical analysis

Cumulative incidence rates of APOs were measured per 1,000 pregnant women within the participant sample, next they were extrapolated to the total amount of APOs in the population observed during the study period using resampling weights based on demographics to minimize selection and misclassification biases (Supplemental file).

Miscarriage, stillbirth, preterm birth, small-for-gestational age as well as a composite outcome of all these APOs were compared according to *C. burnetii* exposure using chi2 or Fisher exact tests. In addition, incidence rate ratios (IRR) of each Q fever related APO were estimated using Poisson regression models for dichotomous outcomes with robust variance option adjusted on hypertensive disorders, diabetes (gestational or pre-gestational), and maternal addictions (smoking or alcohol). Attributable risk percent (*i.e.*, etiologic fractions) among the exposed and population attributable fractions were generated to estimate the contribution of *C. burnetii* exposure to APOs.

All these analyses were performed using Stata 14.2® (StataCorp, College Station, TX, USA). For all estimations, a *P* value <0.05 was considered significant.

## Results

Between May 1 and October 31, 2013, 2,331 pregnant women gave birth or aborted within the level-3 maternity. Of these, 850 (36.4%) were suspected of an APO (Figure 1). Among these, the suspected APO was linked to a known cause of perinatal complication for 668 women and was unexplained for 182 other women. Among these latter, 179 pregnant women consented to be investigated for Q fever and were enrolled in the follow-up study, of whom 118 (65.8%) presented a confirmed APO. The participant women were representative of the reproductive population in terms of demographics, pregnancy-related hypertensive disorders, diabetes, or foetal gender but were less likely to smoke or drink alcohol, and more likely to carry a multiple pregnancy (Table S1). Participant women were also indistinguishable from other women presenting APOs on the aforementioned factors (Table S2).

Of the 179 participants, 19 were seropositive (phase 2 IgG titre  $\geq 1:64$  and/or phase 2 IgM  $\geq 1:48$ ) and 10 presented a profile indicative of an acute infection (phase 2 IgG  $\geq 1:256$  and/or phase 2 IgM  $\geq 1:48$ ). Except patient n°1, who exhibited fever and mild hepatitis, all parturient women were asymptomatic, and the diagnosis was made incidentally at the occasion of the APO event. No persistent infection was identified upon follow-up. The serological profiles and perinatal complications of the seropositive women are presented in Table 1.

Of the 21 APOs observed within the 19 seropositive women, early miscarriage (n = 9) was the most common perinatal complication followed by SGA (n = 5), PTB (n = 3), stillbirth (n = 2), late miscarriage and oligohydramnios (n = 1). For three women with an acute Q fever (n°1, n°2, n°5), the chronology between the onset of the infection and the APO (*i.e.*, temporality) with respect to the kinetics of antibodies

(*i.e.*, seroconversion ensuring biological plausibility) suggested causality in the pathogenesis of the complication.

The incidence of Q fever related APO in the reproductive population was estimated between 2.4‰ and 5.4‰ (1.3 to 4.3‰ in the study sample), whether causality was requested or not, which was in the observed range for TORCH pathogens. Miscarriage featured almost half of this burden (Table S3).

*C. burnetii* exposure or acute Q fever was independently associated with a composite outcome of APOs in a model controlling for major confounders such as pregnancy-related hypertensive disorders, diabetes or maternal addictions (Table 2).

Pregnant women with *C. burnetii* antibodies were more likely to suffer a miscarriage, and there was trend to increase risk for stillbirth at the threshold defining acute Q fever.

Importantly, both risks for miscarriage and stillbirth were highly attributable to the exposure (Table 3), which argues the involvement of *C. burnetii* in their pathogenesis. The population attributable fraction for Q fever exposure was 12%, which means that if Q fever had been fully treatable with antibiotics, the burden of miscarriage should have been less than 88% of that observed.

## Discussion

This prospective study suggests a potential burden of Q fever to APOs in a setting of putative endemic transmission [2], albeit the documentation of human cases and the understanding of transmission pathways in the community remain uncomplete. However, over a very short period of observation and despite a selection of women at risk minimizing the actual proportion of infected women, recent or acute *C. burnetii* infections were deemed responsible of two miscarriages and one late preterm birth, which shed light on a possible reproductive health concern. In support to this finding, the cumulative incidences of Q fever associated APOs was estimated to reach a substantial level that should be considered in daily obstetrical practice. Indeed, this burden was consistent with the figures reported either from endemic [7] or epidemic settings (Table S3) [4,5], and it was also coherent with what observed in Réunion island for TORCH pathogens [16].

This prospective study also supports the strong association between acute or recent Q fever and APOs, especially miscarriage, as previously found in a Spanish case control study [3]. Together with high attributable risk percent suggesting the contribution of Q fever in pathogenesis, our findings argue a causative role for *C. burnetii* infection in miscarriage, and to a lesser extent intrauterine foetal death, as proposed in a meta-analysis [8]. In this latter study, spontaneous abortions were pooled together with stillbirths and early postnatal deaths, which makes unclear the contribution of Q fever to each outcome. Our findings are however in agreement with the Danish cohort study and studies from the Netherlands, which suggest weakening the putative association between Q fever exposure and preterm birth [5,6,17], as that with small-for-gestational age [5,6].

Importantly, we have shown that in the endemic context of Reunion island, acute Q fever may lead to APOs. Although it has not been recommended in post-epidemic situation [18], we advocate in our endemic context that pregnant women with a previous episode of miscarriage or stillborn child or presenting an environmental or occupational risk of Q fever, to be screened before conception, or early in pregnancy, and treated with cotrimoxazole (and acid folic supplementation) at least for five weeks if a seroconversion with phase 2 IgG antibodies occurs, or until delivery if phase 1 IgG antibodies are present, in order to avoid potential harms to the foetus [19] and/or progression to persistent infection [20]. Furthermore, a general information could be given to all pregnant women - as already made for arboviral infections and notably Zika virus - to ensure that they are aware of the risks associated with Q fever during pregnancy and allow then to limit their exposition if possible, for instance by keeping away from farms and avoiding direct contact with ruminants. In case of fever of unknown origin, pneumonia, hepatitis, endocarditis, unexplained perinatal complication, or overt exposure during pregnancy, we endorse investigating acute Q fever as a possible diagnosis with a close monitoring of *Coxiella burnetii* antibodies, and to treat when appropriate [20]. Because placental inoculation may ensue, and though PCRs were negative in our study, we encourage to complete the workup dedicated to foetal issues with a PCR researching the genome in amniotic fluids, placentas and birth products. Because person-to-person transmission of Q fever has been suspected in a maternity ward [21], we strongly recommend precautions in birth product manipulations and quarantine of the infected pregnant woman. Because persistent infection (*e.g.*, endocarditis, vasculitis, osteoarthritis, lymphadenitis) may complicate Q fever onset through pregnancy, ante or postpartum, we propose long-term follow-up of parturient women and screening of secondary localizations [20].

### *Limitations*

#### *Limitations of the study*

First, it was an exploratory investigation performed in the preparedness of an academic funded serosurvey, so that we recognize that it was not powered enough to detect an effect of Q fever on stillbirth while adjusting on relevant confounders. Second, the selection of a control population at risk has certainly diminished the magnitude of the effect of Q fever on APOs. This was a practical conservative option given the impossibility to conduct both simultaneously the serosurvey (under the rules of biomedical research ethics) and this follow-up study (under the rules of standard care research). We believe however this stringent methodological option (known as tip of iceberg epidemiology) makes the results from our local study that more interesting, the real burden being likely underestimated.

## **Conclusion**

Q fever is circulating on Reunion island, including among pregnant women. Given a strain specificity has been found in association with the different clinical manifestations and given the increased risk of miscarriage in our follow-up study, it would be now interesting to identify whether the circulating strain is abortive, as that harbouring the QpDV plasmid [19].

As for mitigation measures aimed at limiting the burden of Q fever on reproduction, pregnant women should be kept away from farms to rule out airborne transmission, avoid direct contact with ruminants, or to consume fresh farm products. In addition, whenever possible, women of childbearing age at risk should be screened before conception or early in pregnancy and be treated with antibiotics to prevent potential harms to the foetus. Our findings should deserve consideration of public health stakeholders and policy makers based in endemic countries to protect communities, especially in rearing areas.

## Abbreviations

APOs: adverse pregnancy outcomes; ARP: attributable risk percent; IFA: indirect fluorescent antibody (alternatively taken as immunofluorescent assay); IgA: immunoglobulin A; IgG: immunoglobulin G; IgG2: phase 2 immunoglobulin G; IgM: immunoglobulin M; IRR: incidence proportion ratio; 95%CI: 95% confidence interval; PAF: population attributable fraction; TORCH: Toxoplasmosis, Other (syphilis, varicella-zoster, parvovirus B19), Rubella, Cytomegalovirus, Herpes).

## Declarations

### *Acknowledgements*

The contributors acknowledge all the staff of the maternity and the members of the CIC-EC de la Réunion, our beloved and regretted friend, Doctor Alain Michault, for funding and benevolent supervision of the E-Q-RUN program, as well as Dr Eric Cardinale at the CIRAD for helpful discussions.

### *Funding*

None.

### *Availability of data and materials*

The dataset generated and/or analysed during the current study are not publicly available due to anonymity policy issues but are available from the corresponding author on reasonable request.

### *Author's contributions*

JJ, SL and PG conceived and designed the experiments. LA, YM, FN, SP and AM performed the experiments including serology assays. CF, HR, MB, PYR provided the data with courtesy from the birth registry and the foetopathology unit. JJ, SL, AB and PG analysed the data. YM wrote the initial draft and PG revised the manuscript, which was extensively reviewed and approved by all authors.

### *Ethics approval and consent to participate*

This standard care protocol was conducted in accordance with the Declaration of Helsinki and the French law for biomedical research and approved by the Ethic Committee of *Centre Hospitalier Universitaire Réunion* as an ancillary research to the E-Q-RUN protocol (Nu ID RCBAFSSAPS: 2013-A00397–38 /

NCT02898402). It allowed the use of clinical, serum and molecular data after oral consent was obtained from all parturient women aged  $\geq 18$  years, as proposed for standard care in French university hospitals.

### *Consent for publication*

Not applicable.

### *Competing interests*

The authors declare that they have no competing interests.

## Tables

**Table 1. Serology titres and perinatal complications of 19 women with Q fever among 179 pregnant women with adverse pregnancy outcomes (APO), Saint Pierre, May to October 2013**

Patient	Age range (years)	Phase 2 IgM	Phase 2 IgG	Phase 1 IgG	APO (weeks)
1	35 to 40	48	256	0	LPTB (36 weeks)
2	31 to 35	96	256	0	EM (9 weeks)
3	15 to 20	0	64	0	SGA+OA (39 weeks)
4	31 to 35	0	128	0	EM (10 weeks)
5	21 to 25	192	1024	128	EM (5 weeks)
6	41 to 45	0	512	128	EM (8 weeks)
7	21 to 25	0	256	0	NGA (39 weeks)
8	26 to 30	0	1024	0	EM (8 weeks)
9	36 to 40	0	256	0	HM+EM (8 weeks)
10	16 to 20	0	256	0	IUFD+LPTB(36 weeks)
11	16 to 20	0	64	0	EM (6 weeks)
12	31 to 35	0	64	0	LM (21 weeks)
13	16 to 20	0	64	0	LPTB+SGA (36 weeks)
14	41 to 45	0	128	0	EM (9 weeks)
15	31 to 35	0	256	0	IUFD+VPTB (32 weeks)
16	36 to 40	0	128	0	EM (9 weeks)
17	26 to 30	0	64	0	VPTB+SGA (31 weeks)
18	36 to 40	0	256	0	SGA (39 weeks)
19	21 to 25	0	128	0	SGA (37 weeks)

EM: early miscarriage (aka spontaneous abortion <12 weeks of gestation); HM: hydatiform mole; LM: late miscarriage (aka, spontaneous abortion 12 to 21 weeks, or birthweight < 500 gr.); IUFD: intrauterine foetal death (aka stillbirth,  $\geq 22$  weeks or birthweight  $\geq 500$  gr.); VPTB: very preterm birth (22 to 32 weeks); LPTB: late preterm birth (33 to 36 weeks); NGA: normal for gestational age; SGA: small for gestational age (intrauterine growth restriction; birthweight <10<sup>th</sup> percentile); OA: oligohydramnios.

Table 2. Adverse pregnancy outcomes associated with Q fever seropositivity in bivariate and multivariate analysis, among 179 pregnant women, Saint Pierre, Reunion island, May to October 2013

Data are numbers, seropositive rates (%), crude and adjusted incidence rate ratios (IRR) and 95% confidence intervals (95% CI). *P* values are given for Pearson chi2 tests. \*Miscarriage, stillbirth, or preterm birth, or small-for-gestational age. #Multivariate Poisson regression model with robust variance option adjusted on hypertensive pregnancy disorders, diabetes (gestational or pregestational), and maternal addictions (smoking or alcohol).

Table 3. Contribution of Q fever infection to adverse pregnancy outcomes among 179 pregnant women with perinatal complications, Saint Pierre, Reunion island, May to October 2013

Adverse	ARP (%)	95% CI	PAF (%)
<b>pregnancy outcomes</b>			
<b>A. Exposure variable : <i>Coxiella burnetii</i> Phase 2 IgG ≥ 1:64</b>			
Composite outcome*	34.7	23.2 - 44.4	5.3
Miscarriage	57.3	28.5 - 74.4	12.4
Stillbirth	52.5	-1.07 - 89.1	10.5
<b>B. Exposure variable : <i>Coxiella burnetii</i> Phase 2 IgG ≥ 1:256 or Phase 2 IgM ≥ 1:48</b>			
Composite outcome*	29.0	10.1 - 43.9	2.2
Miscarriage	51.5	4.7- 75.3	5.6
Stillbirth	76.3	0.2 - 94.2	15.3

Data are attributable fractions among the exposed (ARP or etiologic fractions), 95% confidence intervals (95% CI), and population attributable fractions (PAF). \*Miscarriage, stillbirth, or preterm birth, or small-for-gestational age.
