## **Abstract**

**Background:** Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease characterized by abnormal immune cell activation. This study aimed to investigate differentially expressed long non-coding RNA (lncRNA) in peripheral blood mononuclear cells (PBMCs) in patients with pSS to identify lncRNAs that affect pSS pathogenesis.

**Methods:** Total RNA was extracted from PBMCs of 30 patients with pSS and 15 healthy persons. Transcriptome sequencing was used to screen differentially expressed lncRNAs and mRNAs in 8 RNA samples from the discovery cohort. The differentially expressed mRNAs underwent functional enrichment analysis. A protein interaction relationship (PPI) and ceRNA network was constructed. Real-time PCR was used to validate screened lncRNAs in all 45 RNA samples..

**Results:** 1180 lncRNAs and 640 mRNAs were differentially expressed in pSS patients (fold change > 2 in healthy persons). The PPI network was constructed with 640 mRNAs and a ceRNA network with four key lncRNAs (GABPB1-AS1, PSMA3-AS1, LINC00847 and SNHG1). RT-PCR revealed that GABPB1-AS1 and PSMA3-AS1 were significantly upregulated 3.0- and 1.4-fold in the pSS group, respectively. The GABPB1-AS1 expression level was positively correlated with the percentage of B cells and IgG levels.

**Conclusions:** GABPB1-AS1 was significantly upregulated in pSS patients, and its expression level is positively correlated with the percentage of B cells and IgG levels.

GABPB1-AS1 may be involved in the pathogenesis of pSS.

**Keywords:** LncRNA, GABPB1-AS1, Sjogren's Syndrome, PBMC

## **1. Background**

Primary Sjogren's syndrome (pSS) is a chronic autoimmune disease which clinically presents with endocrine gland dysfunction, mainly occurring in the salivary and lacrimal glands. Histopathology typically shows infiltration of lymphocytes. In particular, large amounts of activated B lymphocytes are observed, which produce a variety of autoantibodies and cytokines; this is related to the occurrence and development of the disease. Although multiple factors such as genetic and environmental factors are thought to be related to this abnormal cellular activity, the specific mechanisms of pSS have not been fully elucidated.

Non-coding RNAs are RNA sequences in the human genome that cannot encode proteins and are largely categorized into short-chain non-coding RNAs (microRNAs, miRNAs) (<200 nt) and long-chain non-coding RNA functions (>200 nt). A large number of studies have shown that miRNAs participate in regulating the pathogenesis of some autoimmune diseases due to their control of gene expression [1, 2]. Moreover, miRNAs affect the development of Sjögren's syndrome [3]. Unlike miRNAs, the functions of most lncRNAs are largely unknown because their structure and regulatory patterns are more complex than miRNAs. The known lncRNAs appear to exert a regulatory role in gene transcription or expression and function as scaffold molecules to regulate the expression of certain miRNA target genes [4]. Therefore,

lncRNAs may affect the development of autoimmune diseases by regulating gene expression during immune cell differentiation and immune responses.

Some preliminary studies have found the role of lncRNAs in regulating gene expression, consequently affecting the pathogenesis of immune diseases. For example, a study showed that lncRNA NeST affects microbial susceptibility by increasing interferon- $\gamma$  (IFN- $\gamma$ ) levels in activated CD8(+) T cells [5]. lncRNA NEAT1 regulates chemokine and cytokine expression and contributes to the progression of systemic lupus erythematosus [6]. lncRNA Hotair expression in differentiated osteoclasts and rheumatoid synovial cells is closely related to a significant increase in MMP-2 and MMP-13 levels, suggesting that lncRNA Hotair participates in rheumatoid arthritis by promoting matrix metalloproteinase (MMP) production [7]. lncRNA FIRRE regulates the expression of VCAM1, IL-12p40, and other inflammatory genes in the innate immune system at the post-transcriptional level [8]. It can promote B cell proliferation by activating the Wnt/ $\beta$ -catenin pathway and it is related to the pathogenesis of diffuse large B cell lymphoma [9]. Based on the previous studies, lncRNAs are expected to be biomarkers for disease diagnosis or therapeutic targets. To date, the correlation between lncRNAs and pSS has not been well studied.

This study analyzed lncRNA and mRNA expression profiles in peripheral blood mononuclear cells (PBMCs) of patients with pSS using transcriptome sequencing and identified lncRNAs related to pSS. Our findings provide a new perspective for the pathogenesis study and identified potential disease-related biological markers and therapeutic targets for pSS.

## 2. Result

### 2.1 Patient characteristics

The characteristics of the 30 pSS patients are shown in **Table 1**. The enrolled patients were positive for antinuclear antibodies ( $\geq 1:80$ ), in which 25 and 8 patients were positive for anti-SSA/Ro antibodies and anti-SSB/La antibodies, respectively. Ocular and oral dryness were reported in approximately 20 and 24 patients, respectively. Lymphocyte infiltration was found in 25 patients who underwent labial salivary gland biopsies. The median ESSDAI score was 3.8, the median B cell/lymphocyte was 13.4%, and the mean IgG was  $16.3 \pm 4.3$  g/L. B cell lymphoma occurred in one patient after three months in the study.

### 2.2 High-throughput lncRNA and mRNA expression profile in PBMC

We found 1180 lncRNAs and 640 mRNAs with significantly different expression in the PBMC of pSS patients based on transcriptome sequencing (fold change  $>2$ ,  $p < 0.05$ ). The upregulated genes included 497 lncRNAs and 256 mRNAs. The downregulated genes included 683 lncRNAs and 384 mRNAs. The differentially expressed genes are displayed using a volcanic map (**Fig. 1a**) and heatmap (**Fig. 1b**). **Tables 2** and **3** list the 15 most upregulated and downregulated DE lncRNAs and DE mRNAs.

### 2.3 Functional prediction and PPI network of DE mRNAs

The 640 DE mRNAs were subjected to GO and KEGG pathway detection to determine the correlation of signaling pathways to pSS pathological mechanisms. **Table 4** lists the top 30 significant GO enrichment of differentially expressed mRNAs. Significantly enriched biological processes (BPs) known to affect pSS include immune response, chemokine-mediated signaling pathway, cell adhesion, type I interferon signaling pathway, and inflammatory response. Significantly enriched pathways include chemokine signaling pathway, PI3K-Akt signaling pathway, transcriptional misregulation in cancer, natural killer cell-mediated cytotoxicity, and cytokine-cytokine receptor interaction (**Table 5**).

According to the description in the Methods section, we obtained 2033 protein interaction pairs in 488 DE mRNAs, including 201 upregulated genes and 287 downregulated genes. The PPI network of 640 DE mRNAs was built, and two important functional modules were obtained (**Fig. 2a**). **Table 6** shows the top 10 genes which resulted from the network connectivity analysis, among which IL-6, IL-10, and CXCL8 are at the center of the network and possibly the hub genes in the PPI network (**Fig. 2b and 2c**). Through module analysis, we obtained two important functional modules. Module 1 contains 30 genes and 292 interaction pairs, while module 2 contains 33 genes and 266 interaction pairs. The pathways that the genes in module 1 are involved in include the calcium signaling pathway, cytokine-cytokine receptor interaction, and chemokine signaling pathway (**Fig. 2d**). The pathways that the genes in module 2 are involved in include natural killer cell-mediated cytotoxicity,

cytokine-cytokine receptor interaction, and Jak-STAT signaling pathway (**Fig. 2e**).

These genes and pathways are known to influence the pathogenesis of pSS.

#### ***2.4 CeRNA network of four selected lncRNAs***

The regulation network of the top 15 upregulation and downregulation DE lncRNAs predicted by Trans and Cis regulation was constructed (**Fig. 3a**). Among them, GABPB1-AS1 regulates 187 genes, including two upregulated genes (TRPM4 and SPATS2L) and two downregulated genes (SCUBE1, CTD-2192J16.20). To verify whether the DE lncRNAs were involved in the pathogenesis of pSS via interaction with miRNA, the top 15 of upregulated and downregulated DE lncRNAs were selected to construct the ceRNA network based on starBase. Only experimentally validated miRNA or mRNA targets annotated in the software were retained. Four lncRNAs, including GABPB1-AS1, PSMA3-AS1, LINC00847, and SNHG1, were obtained and their ceRNA network is shown in Figure 3b. In this ceRNA network, there are 17 pairs of lncRNA-miRNA regulating relationships, 11 pairs of lncRNA-mRNA regulating relationships, and 155 pairs of miRNA-mRNA regulating relationships. **Fig. 4** shows the co-expression relationship between GABPB1-AS1, PSMA3-AS1 and several significantly upregulated mRNA (IFI44, IFI44L, IFI6, EPSTI1) based on transcriptome sequencing.

#### ***2.5 Validation with real-time PCR and function analysis***

Two differentially expressed lncRNAs were chosen for further validation in an independent cohort including 30 patients with pSS and 15 healthy controls. The selected lncRNAs and their primers are presented in **Additional file 1**. The results demonstrate that GABPB1-AS1 and PSMA3-AS1 are significantly upregulated 3.0- and 1.4-fold, respectively, in the pSS group compared to the healthy control (**Fig. 5a**). We further investigated the correlation of the two lncRNAs with clinical characteristics in patients with pSS and health controls. We found that the expression level of GABPB1-AS1 is positively correlated with the percentage of B cells and IgG levels (**Fig. 5b**). While the expression level of PSMA3-AS1 has no significant correlation with the percentage of B cells and IgG levels. (**Fig. 5c**)

### **3. Discussion**

Recent evidence has demonstrated the essential role of lncRNAs in various types of autoimmune diseases including pSS due to their control of gene expression at multiple levels. Shi et al revealed eight significantly upregulated lncRNAs in labial salivary glands in pSS patients and observed correlation between these lncRNAs and some clinical characteristics[10]. LncRNA TMEVPG1 and lncRNA PVT1 were found in another two studies to be upregulated in CD4(+) T cells of pSS patients and were suggested to be involved in the pathogenesis of pSS[11,12]. However, the potential role of lncRNAs in pSS is still far from known. In this study, we payed attention to the expression profile of lncRNAs in PBMC. We screened out DE mRNAs and DE lncRNAs that may play a role in pSS, constructed their regulatory

networks, and attempted to identify the key lncRNAs that affect the pathogenesis of pSS.

Many biological processes are related to the pathogenesis of pSS, such as cell apoptosis, cell adhesion, inflammatory response, and immune response mediated by type I interferon signaling, interferon-gamma signaling, and cytokine-mediated signaling pathways [13]. In this study, GO and KEGG pathway functional enrichment analysis of DE mRNA showed that biological processes were significantly enriched in the chemokine-mediated signaling pathway, immune response, inflammatory response, cell adhesion, and type I interferon signaling pathway. The most significantly enriched cellular components were the plasma membrane, extracellular region, integral component of membrane, and extracellular exosome. The most significantly enriched molecular functions were calcium ion binding, protein homodimerization activity, receptor activity, and heparin binding. The most significantly enriched pathways were cytokine-cytokine receptor interaction, PI3K/AKT signaling pathway, natural killer cell-mediated cytotoxicity, transcriptional misregulation in cancer, and chemokine signaling pathway.

Type I interferon signaling has been found in the pathogenesis of many rheumatic diseases, as well as in pSS. Type I interferon signature genes (ISGs), such as IRF5 and STAT4 [14, 15], have been considered as susceptibility factors in pSS. In patients with pSS, peripheral blood type 1 interferon signature correlates with the existing anti-SSA/Ro antibodies, higher BAFF gene expression in monocytes, and clinical disease activity [16, 17]. IFI44 and IFI44L, two molecules of ISGs, have been

identified as two of the hub genes that may be involved in the development of pSS [18, 19]. In this study, several ISGs, including IFIT1B, IFI27, IFI44, IFI44L, and IFI6, were found to be significantly upregulated in the PBMC of pSS patients, which suggested the activation of type 1 interferon signaling in these patients.

Another significantly upregulated gene in this study was EPSTI1. Recent studies have recognized elevated EPSTI1 levels as a promoter for B cell activation by activating TLR9 signaling and considered it a key factor for pSS pathogenesis [20]. In the present study, through the analysis of the PPI network of DE mRNAs, we identified several hub genes, including IL6, IL10, and CXCL8, which are important genes in autoimmune diseases and inflammatory pathways. Based on these findings, we believe that there is an active autoimmune inflammatory response in patients with pSS.

From the top 15 upregulated and downregulated DE lncRNAs, we chose four lncRNAs, GABPB1-AS1, PSMA3-AS1, LINC00847, and SNHG1, and constructed their ceRNA network. Two were validated using real-time PCR in an independent cohort that included 30 patients with pSS and 15 healthy controls. The results indicated that GABPB1-AS1 and PSMA3-AS1 were significantly upregulated in patients with pSS. LncRNA GABPB1-AS1 has been shown to play an important role in cancer pathogenesis through a mechanism that controls gene expression. For example, GABPB1-AS1 is an lncRNA associated with autophagy and may play a key role in glioma biology [21]. GABPB1-AS1 was significantly upregulated in HPV16-positive cervical cancer tissues and associated with a poor prognosis in these

patients [22]. It has been shown that GABPB1-AS1 regulates cellular oxidative stress in liver tumor cells and may be an attractive therapeutic target for hepatocellular carcinoma [23]. GABPB1-AS1 inhibited renal cell carcinoma growth and played a tumor suppressor role [24]. Interestingly, our further analysis showed that the expression level of GABPB1-AS1 was positively correlated with interferon signature genes (IFI44, IFI44L, IFI6), as well as EPSTI1. Therefore, we predicted that GABPB1-AS1 might participate in the pathogenesis of pSS by affecting type 1 interferon signaling.

B cell-activating factor (BAFF) was discovered to be essential in pSS pathogenesis by promoting the activation and proliferation of B cells and was reported to be significantly upregulated in PMBC of pSS patients [25, 26]. According to the prediction in the StarBase database, GABPB1-AS1 interacts with miR-16-5p and miR-155-5p. miR-16 has been shown to be involved in the occurrence of several autoimmune diseases, as well as in pSS, by controlling cytokine expression [27]. miR-155 is an important regulator of B cell activation through the TNF- $\alpha$ /BAFF/CD19 signaling pathway [28, 29]. However, miRNAs can act as a “sponge” by lncRNAs to achieve regulatory functions. Therefore, we deduced that GABPB1-AS1 may regulate the activation of B cells by interacting with miR-16 or miR-155. However, this regulatory relationship or other potential regulatory mechanisms underlying differentially expressed lncRNAs affecting pSS pathogenesis needs further experimental verification.

#### **4. Conclusion**

In this study, we identified two significantly upregulated lncRNAs, GABPB1-AS1 and PSMA3-AS1, in pSS patients compared to health controls. GABPB1-AS1 was found to be upregulated 3.0-fold in pSS patients, and its expression level is positively correlated with the percentage of B cells and IgG levels in pSS patients. GABPB1-AS1 is predicted to play an important role in the pathogenesis of pSS.

This study add new evidences on the importance of lncRNAs in the pathogenesis of pSS and may open promising avenues for novel diagnosis method and therapeutic target to the disease.

## **5. Methods**

### ***5.1 Patients***

Thirty female patients diagnosed with pSS and 15 sex- and age-matched healthy persons were recruited from the Second Affiliated Hospital of Zhejiang University. The enrolled pSS patients met the diagnostic criteria of the 2016 American College of Rheumatology (ACR)–European League against Rheumatism (EULAR). The severity of dryness was evaluated using the patient-reported visual analogue scale (VAS). Results of laboratory tests and salivary gland biopsy were collected, as well as systemic involvement of the patients. The disease activity of pSS patients was evaluated using the Eular Sjogren’s syndrome disease activity index (ESSDAI). The enrolled patients did not have immunosuppressive treatment prior to blood specimen collection. Peripheral venous blood samples (5 mL) were extracted from each participant using BD Vacutainer K2EDTA tubes, and PBMCs were immediately

isolated by Ficoll-Hypaque density gradient separation. Trizol was added to PBMC samples immediately, then cells were lysed and subjected to total RNA extraction. This mixture was stored in a  $-80\text{ }^{\circ}\text{C}$  refrigerator until RNA extraction. The discovery cohort was composed of 4 pSS patients and 4 healthy controls, and the independent validation cohort was composed of 30 pSS patients and 15 healthy controls.

Prior to the blood sample collection, written informed consent was obtained from the participants. The protocols used in this study were performed following the principles of the Helsinki declaration and were approved by the Ethical Committee.

### ***5.2 RNA extraction and purification***

Total RNA was extracted from PBMCs using the miRNeasy Mini Kit (Qiagen, Germany) following the manufacturer's instructions. High-purity RNA was obtained using the RNAClean XP Kit (Beckman Coulter, USA) and RNase-Free DNase Set (Qiagen). RIN number of RNA samples was detected on an Agilent Bioanalyzer 2100 (Agilent Technologies, USA) and NanoDrop ND-2000 spectrophotometer to evaluate RNA integrity. Samples with qualified measurements (2100 RIN  $\geq 7.0$ , 28S/18S  $\geq 0.7$ ) were included in the subsequent transcriptome sequencing.

### ***5.3 Transcriptome sequencing***

Eight RNA samples from the discovery cohort were used for transcriptome sequencing. Sequencing RNA sample library construction was performed through a series of steps, including rRNA removal, fragmenting, first-strand cDNA synthesis, second-strand cDNA synthesis, terminal repair, plus A to 3' end, junction jointing, and

enrichment. The concentration was determined using a Qubit®2.0 Fluorometer and library size on Agilent 4200.

Cluster generation and first-to-sequencing primer hybridization were conducted on the cBot with the Illumina sequencer following the procedures acquired from the cBot instruction. Sequencing reagents were prepared according to the Illumina user guide, and flow cells carrying clusters were used for double-ended sequencing by the paired-end program. Data collection software of Illumina was controlled and analyzed in real-time the sequencing process.

Using high throughput sequencing (Illumina Hiseq 2000/2500 and Miseq) for next generation sequencing (NGS), the raw reads were pre-processed for genome mapping using a genome version of hg38 ([ftp://ftp.ensembl.org/pub/release-90/fasta/homo\\_sapiens/dna/Homo\\_sapiens.GRCh38.dna.toplevel.fa.gz](ftp://ftp.ensembl.org/pub/release-90/fasta/homo_sapiens/dna/Homo_sapiens.GRCh38.dna.toplevel.fa.gz)). The number of reads was converted to FPKM values after fragment counting and normalization. Finally, 38096 lncRNAs and 50869 mRNAs were investigated.

After eliminating the low-expressed genes in the data (genes whose raw count was 0 in more than 75% samples), genes with a different expression between pSS samples and health samples were analyzed by edgeR. Meanwhile, we calculated the differential expression multiple (fold-change) based on the FPKM value. LncRNA and mRNA expression with a fold-change >2 and a p-value less than 0.05 were considered to be differentially expressed genes.

#### ***5.4 Bioinformatics analysis***

GO and KEGG functional enrichment analysis of mRNAs with different expression levels was accomplished using the DAVID online tool (<https://david.ncifcrf.gov/>; version 6.8). The results include BP (Biological Process), CC (Cellular Component), and MF (Molecular Function). The Fisher test was used, and the enrichment threshold was set at p-value <0.05.

The protein interaction relationship (PPI) of differentially expressed genes was obtained using the STRING (<http://www.string-db.org/>; version 10.0) database. PPI networks of differentially expressed genes were constructed using Cytoscape software (version 3.2.0). In the PPI networks, functional modules were identified by the MCODE plug-in of Cytoscape software, and finally, biologically meaningful protein complexes were obtained. Parameters were as follows: include loops: false degree cutoff: 10, node score cutoff: 0.2, cut: true, FF: false, K-Core: 2, max. depth from seed: 100. GO and KEGG pathway enrichment analyses of genes in the modules were carried out.

lncRNA target genes were predicted using Trans and Cis regulation. Cytoscape software was used to construct the regulation network of top 15 upregulation and downregulation differential expression (DE) lncRNAs. The ceRNAs of these DE lncRNAs were predicted in the StarBase Database (<http://starbase.sysu.edu.cn/>; version 2.0). The miRNA targets of DE mRNA were predicted using the MiRDB Database (<http://www.mirdb.org/>). Combined with pSS-related miRNAs obtained from the HMDD Database (version 3.2) (<http://www.cuilab.cn/hmdd>), the lncRNA-miRNA-mRNA network, or the ceRNA network, was constructed.

### **5.5 Real-time PCR**

The lncRNAs screened for abnormal expression were validated using real-time PCR in all the 45 extracted RNA samples. The lncRNAs we screened were based on the following criteria: (1) fold change  $\geq 4$ , (2) average FPKM of the upregulated group  $\geq 5$ , (3) without repeated sequences of mRNA, and (4) lncRNAs without information in databases were excluded.

The purified total RNA was reverse transcribed into cDNA using the ReverTra Ace qPCR Kit (TOYOBO, FSQ-101). The obtained cDNA sample was subjected to real-time quantitative PCR using the Power SYBR Green PCR Master Mix (ABI, USA). A QuantStudio 5 Real-Time PCR System (ABI) was used for the PCR procedures. LncRNA expression was measured and normalized to the mean expression of the housekeeping gene: GAPDH (Additional file 1). The relative fold change of each sample was calculated in relation to the  $\Delta Ct$  of a random unstimulated sample (reference) in the health control group according to the formula: fold change =  $2^{-\Delta\Delta Ct}$ , where  $\Delta\Delta Ct = \Delta Ct \text{ sample} - \Delta Ct \text{ reference}$ .

### **5.6 Statistical analyses**

GraphPad Prism 7.0 version was used for statistical analysis of the data. Data are represented as fold changes relative to healthy controls. Correlation analysis was performed by Spearman's test. An analysis based on the two-tailed unpaired t-test or Mann-Whitney U test was performed to evaluate differential expression of genes between groups. The significant difference was the p-value of less than 0.05.

**Additional file 1.** The selected lncRNAs and the housekeeping gene (GAPDH) and their primers.

**List of abbreviations:** pSS:primary Sjögren's syndrome; lncRNA:long non-coding RNA; PBMC:peripheral blood mononuclear cell; PPI:protein interaction relationship; miRNA:short-chain non-coding RNA; IFN- $\gamma$ :interferon- $\gamma$ ; MMP:promoting matrix metalloproteinase; ACR:American College of Rheumatology; EULAR:European League against Rheumatism; VAS:visual analogue scale; ESSDAI:Eular Sjogren's syndrome disease activity index; NGS:next generation sequencing; DE:differential expression; ISG:interferon signature gene; BAFF:B cell-activating factor.

## Tables

Table 1. The detailed demographic, clinical, and laboratory characteristics of 30 pSS patients

Indexes	RNA sequencing(n=4)	PCR validation(n=30)
Sex, no. Male/female	0/4	0/30
Age, mean (SD) years	47.0(12.1)	52.7 (13.1)
Disease duration, median (IQR) years	3.5(1.0)	1.0(6.2)
Oral dryness (VAS,1-10), median (IQR)	5.0(2.0)	5.5(4.3)
Ocular dryness (VAS,1-10), median (IQR)	3.5(1.0)	3.0(5.3)
Grading of labial salivary gland biopsies, no.		
Grade2, no.	0	1
Grade3, no.	2	11
Grade4, no.	2	13
IgG (g/L), mean ± SD	14.9(2.5)	17.5(3.4)
C3 (g/L), mean ± SD	0.89(0.24)	0.83(0.24)
C4 (g/L), mean ± SD	154.3(48.1)	156.8(72.6)
ESR (mm/h), mean ± SD	25(19)	30(45)
RF (IU/mL), mean ± SD	12.4(2.7)	12.7(19.8)
SSA, no. +/-	4/0	25/5
SSB, no. +/-	1/3	8/22
B cell, %, median (IQR)	23.1(8.3)	18.2(7.8)
ESSDAI score, median (IQR)	2.5(1.0)	3.8(1.9)

SD: standard deviation; IQR: inter-quartile range; VAS: visual analogue scale;

Table 4. The Top 30 of significant GO enrichment (biological process, molecular function, and cellular component) of differential expressed mRNAs.

<b>GO enrichment</b>	<b>Fold enrichment</b>	<b>Gene number</b>	<b>P value</b>	<b>GO domain</b>
cellular ion homeostasis	18.832	3	0.009	Biological process
branching involved in labyrinthine layer morphogenesis	13.950	4	0.002	
response to yeast	12.072	5	0.001	
activation of transmembrane receptor protein tyrosine kinase activity	10.462	4	0.006	
labyrinthine layer blood vessel development	8.260	5	0.003	
positive regulation of cytokine production	7.847	6	0.001	
negative regulation of viral genome replication	7.062	9	<0.001	
chemokine-mediated signaling pathway	6.631	15	<0.001	
regulation of angiogenesis	6.075	6	0.003	
positive regulation of peptidyl-threonine phosphorylation	5.812	5	0.010	
defense response to fungus	5.812	5	0.010	
response to cold	5.231	6	0.005	
cell maturation	5.231	6	0.005	
cellular defense response	5.062	10	<0.001	
positive regulation of angiogenesis	4.913	18	<0.001	
calcium-mediated signaling	4.308	7	0.005	
wound healing	3.923	10	0.001	
type I interferon signaling pathway	3.923	8	0.004	
positive regulation of protein kinase B signaling	3.737	10	0.001	
cellular response to interleukin-1	3.537	8	0.007	
immune response	2.908	39	<0.001	
defense response to virus	2.853	15	0.001	
chemotaxis	2.830	11	0.006	
azurophil granule	11.667	4	0.004	Cellular component
collagen trimer	3.487	10	0.002	
chemokine receptor activity	9.350	5	0.002	Molecular function
growth factor binding	5.887	5	0.010	
chemokine activity	5.190	8	0.001	
heparin binding	3.576	18	<0.001	
receptor activity	2.930	20	<0.001	

Table 5. Significantly enriched pathways of differential expressed mRNAs

<b>Kegg pathway enrichment</b>	<b>Fold enrichment</b>	<b>Gene number</b>	<b>P value</b>
Malaria	4.044	26	1.14E-06
Cytokine-cytokine receptor interaction	3.029	15	0.002
Protein digestion and absorption	2.574	16	0.002
Transcriptional misregulation in cancer	2.543	7	0.007
Chemokine signaling pathway	2.435	10	0.028
Natural killer cell mediated cytotoxicity	2.320	14	0.034
Rap1 signaling pathway	1.887	20	0.034
PI3K-Akt signaling pathway	1.641	8	0.035

Table 6. Top10 in the result of PPI network connectivity analysis

<b>Gene</b>	<b>Type</b>	<b>Degree</b>
IL6	Up	90
CXCL8	Down	73
IL10	Up	64
NCAM1	Down	49
MYC	Down	46
IL15	Up	45
CCL4	Down	43
GZMB	Down	42
PRF1	Down	38
CXCR6	Down	38

PPI: protein interaction relationship

## Figure legends

**Figure 1. Expression profile of LncRNAs and mRNAs in pSS patients.** PBMC of pSS patients and healthy persons were collected for transcriptome sequencing analysis. The differentially expressed lncRNAs and mRNAs were illustrated using (a) volcanic map and (b) heatmap. Downregulation and upregulation are represented in blue and red, respectively, in the volcanic map.

**Figure 2. PPI network of DE mRNAs.** (a) PPI network of 640 DE mRNAs, (b) functional module 1, and (c) functional module 2. (d) Pathways identification in module 1 by KEGG pathway. (e) Pathways identification in module 2 by KEGG pathway.

**Figure 3. CeRNA network of selected lncRNAs.** (a) The regulation network of the top 15 upregulation and downregulation DE lncRNAs predicted by Trans and Cis regulation. (b) CeRNA network of four key lncRNAs based on starBase.

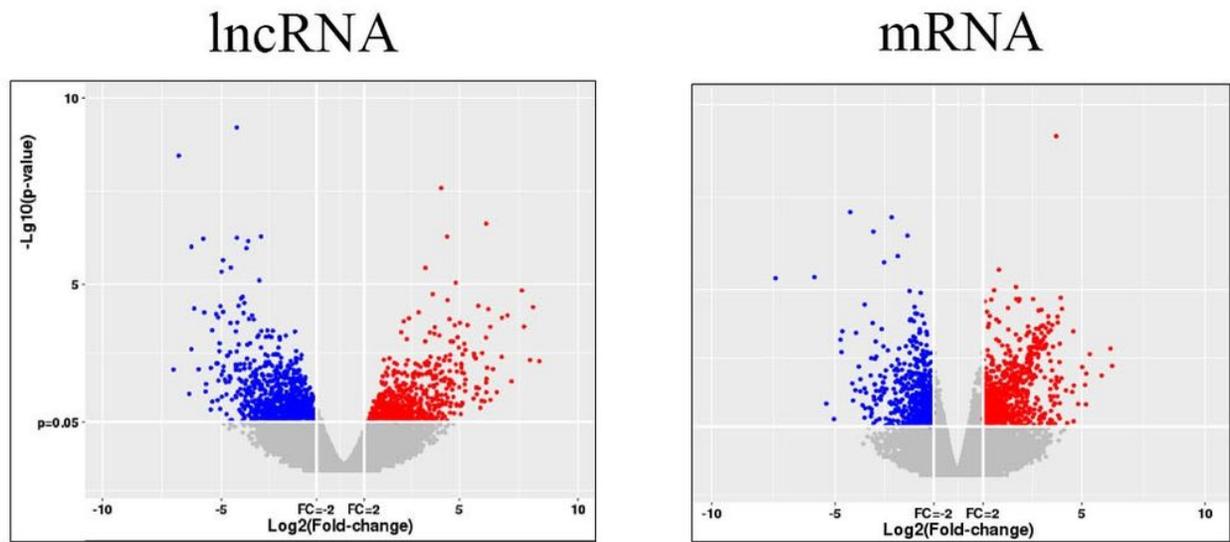

**Figure 4. Correlation analysis between two upregulated LncRNAs and upregulated mRNAs (IFI44, IFI44L, IFI6, EPSTI1).** (a) GABPB1-AS1. (b)PSMA3-AS1.

**Figure 5. Correlation analysis between GABPB1-AS1 and PSMA3-AS1 and pathological factors.** (a) GABPB1-AS1 and PSMA3-AS1 expression levels in pSS patients (n=30) and healthy persons (n=15) were determined using real-time PCR. (b)

Correlation analysis between GABPB1-AS1 and B cell and IgG levels in pSS patients and health controls. (c)Correlation analysis between PSMA3-AS1 and B cell and IgG levels in pSS patients and health controls. The percentage of CD19+ B cells was detected by flow cytometry and IgG was measured by ELISA. The significant difference was  $p < 0.05$ .
