Abstract

Introduction

[¹⁸F]PSMA-1007 has potential advantages over [⁶⁸Ga]Ga-PSMA-11, although limited prospective data evaluating diagnostic performance exist. The aims of this study are to describe the concordance of [¹⁸F]PSMA-1007 and [⁶⁸Ga]Ga-PSMA-11 for TNM with American Joint Committee on Cancer (AJCC) prognostic stage, and assess differences in tracer uptake.

Methods

Fifty men (mean age 71.8) were imaged with [⁶⁸Ga]Ga-PSMA-11 and [¹⁸F]PSMA-1007 < 4 weeks apart. Images were independently reported according to TNM by two experienced nuclear medicine specialists blinded to the other scan and prior imaging. Discordant results were resolved by a third independent nuclear medicine specialist. Quantitative analysis of lesion uptake and physiologic tissue for each tracer was performed by one experienced reader.

Results

Scan indications were initial staging (n = 12), biochemical recurrence (n = 27) and metastatic disease evaluation (n = 11). Most patients had ISUP grade group 3 or higher. Median PSA value was 2.7 ng/ml (IQR 0.7–12.0) and a minority of patients (28%) were currently treated with androgen deprivation therapy. [¹⁸F]PSMA-1007 uptake was significantly higher than [⁶⁸Ga]Ga-PSMA-11 in local recurrence, nodal and distant metastases, and most physiologic sites except for urinary bladder which was significantly lower. [¹⁸F]PSMA-1007 upstaged local prostate staging in 5/17 patients, local recurrence in 3/33 patients, regional nodal disease in 3/50 patients and 1 distant metastasis (bladder). [⁶⁸Ga]Ga-PSMA-11 upstaged regional nodal disease in 1/50 patients and distant metastasis in one patient (right adrenal). Overall AJCC prognostic stage was concordant in 46/50 (92%) patients, with two patients upstaged for both [¹⁸F]PSMA-1007 and [⁶⁸Ga]Ga-PSMA-11. [¹⁸F]PSMA-1007 had more equivocal results (one regional node; six equivocal bone lesions, one of which was subsequently confirmed metastatic) than [⁶⁸Ga]Ga-PSMA-11 (one equivocal local recurrence).

Conclusion

Overall AJCC prognostic stage was similar (92%) between [¹⁸F]PSMA-1007 and [⁶⁸Ga]Ga-PSMA-11. [¹⁸F]PSMA-1007 demonstrates higher uptake within involved nodes and distant metastases, and most physiologic sites except urinary bladder which aided [¹⁸F]PSMA-1007 local staging of the prostate primary / local recurrence and regional nodal disease adjacent ureters. However [¹⁸F]PSMA-1007 liver uptake obscured a solitary right adrenal metastasis, and more equivocal bone lesions were identified.

Introduction:

Prostate cancer is responsible for an estimated 366 000 deaths annually worldwide and is the most commonly diagnosed male cancer in Australia(1). The early detection and accurate staging of prostate cancer is crucial for the implementation of appropriate therapies. Prostate specific membrane antigen (PSMA) is a type II transmembrane glycoprotein present on prostate epithelial cells that is significantly over-expressed in prostate malignancy, correlating with androgen independence, metastasis, disease progression and Gleason score(2, 3). A number of PSMA-binding radiopharmaceuticals have been developed, particularly the PET tracers [⁶⁸Ga]Ga-PSMA-11, [¹⁸F]PSMA-DCFPyL and [¹⁸F]PSMA-1007. The first of these, [⁶⁸Ga]Ga-PSMA-11 rapidly became commonly used and suggested as the new standard of care for staging(4), re-staging at biochemical recurrence(5) and theranostic approach to prostate malignancy(6) given its superior sensitivity and specificity, interobserver reliability(7) and correlation with [¹⁷⁷Lu]Lu-PSMA-617 tumour dosimetry and treatment outcomes(8).

There are several limitations to [⁶⁸Ga]Ga-PSMA-11 restricting more widespread adoption and use. Gallium-68's (⁶⁸Ga) short half-life of 68 minutes limits tracer usage to large centres to justify the cost of an on-site generator to produce the radiotracer. Each production run is labour intensive and produces only enough activity for approximately three patient doses. Urinary excretion of [⁶⁸Ga]Ga-PSMA-11 radiotracer may also limit identification of small volume disease adjacent to the ureters, bladder and prostatic urethra(9) requiring use of contrast or diuretics and their associated side effects in some centres. Intense urinary uptake in the bladder and kidneys may also lead to a flair/halo artefact, limiting the detection of disease in adjacent pelvic tissues(10). Furthermore, incorrect ⁶⁸Ga dose calibration may impact upon quantitative accuracy(11).

More recently developed [¹⁸F]PSMA-1007 and [¹⁸F]PSMA-DCFPyL are labelled with fluorine-18 (¹⁸F) which has a longer radioactive half-life of 110 minutes, enables central manufacture for distribution to satellite centres and more efficient labour manufacture costs. ¹⁸F also exhibits a lower positron energy (0.65 MeV) when compared with ⁶⁸Ga (1.9 MeV), theoretically yielding higher spatial resolution. Furthermore, [¹⁸F]PSMA-1007 biodistribution studies demonstrate reduced accumulation in the bladder than seen with [⁶⁸Ga]Ga-PSMA-11 or 18F-DCFPyL offering theoretical advantages for locoregional staging adjacent the urinary bladder and ureters. Early small retrospective studies demonstrate similar outcomes for evaluation of staging (12, 13), biochemical recurrence(14, 15) and theranostic applications(16). However, a retrospective matched-pair comparison of [⁶⁸Ga]Ga-PSMA-11 and [¹⁸F]PSMA-1007 PET/CT demonstrated higher numbers of avid lesions attributed to a benign origin(17). A small (n=16) prospective comparison between the two tracers with histopathologic correlation was restricted to intraprostatic assessment(18), and another assessed the role of [¹⁸F]PSMA-1007 in selected patients with equivocal or oligometastatic scans using a variety of renally excreted tracers(19). The aim of this study was to conduct a comprehensive, prospective intra-individual comparison of [¹⁸F]PSMA-1007 and [⁶⁸Ga]Ga-PSMA-11 in a broad cohort of patients to evaluate physiologic biodistribution and accuracy for staging, biochemical recurrence and metastatic disease.

Materials And Methods:

The institutional review board of the Royal Brisbane and Women's Hospital approved this prospective, single-centre study (HREC/17/QRBW/686) and all patients provided written informed consent. The study was conducted according to local regulations and laws, the ethical principles in the Declaration of Helsinki and the principles of Good Clinical Practice. The study was registered with the Australian New Zealand Clinical Trials Registry (ACTRN12618000665235).

Patient Selection

From May to December 2018, 50 men were recruited according to the following eligibility criteria: (a) aged 18 years or older, (b) provided informed consent and able to comply with the study procedures, and (c) fit the criteria for one of the following scan indication categories: primary staging, biochemical recurrence (post-prostatectomy or post-radiotherapy) or restaging of distant metastatic disease. Primary staging was defined as newly diagnosed, untreated, prostate cancer based on biopsy proven intermediate-high risk adenocarcinoma Gleason grade group 3,4 or 5 and/or prostate specific antigen (PSA) greater than 20 ng/mL and/or clinical stage T3 or greater. Biochemical recurrence was defined in the post-prostatectomy setting as PSA 0.2 ng/mL or greater above the nadir following prostatectomy (R0- or R1- resection), and post-radiotherapy as PSA increase of 2 ng/mL above the lowest recorded PSA value following organ-preserving local treatment (external beam radiotherapy or brachytherapy). Metastatic disease was defined as known metastatic prostate cancer diagnosed by at least one of [⁶⁸Ga]Ga-PSMA-11, whole body bone scan, CT or MRI imaging or histopathologic confirmation of prostate cancer metastasis. Exclusion criteria was significant comorbidity that would limit compliance with the study protocol.

Radiotracer Synthesis

[⁶⁸Ga]Ga-PSMA-11 (Scintomics GRP platform) and [¹⁸F]PSMA-1007 (GE FASTlab or MX Tracerlab platforms) were manufactured on site using a kit-based approach on automated platforms, with comprehensive quality control testing of each batch to monograph standards for other Ga-68 and F-18 radiopharmaceuticals respectively (pH, chemical and radiochemical purity, radionuclide identity and purity, residual solvents, sterilising filter integrity, endotoxin and sterility). Product radiochemical purity was measured by high performance liquid chromatography (HPLC) with a pre-defined acceptance criterion of >91% [⁶⁸Ga]Ga-PSMA-11 and >95% [¹⁸F]PSMA-1007.

Image Acquisition

All patients underwent PET/CT imaging with [⁶⁸Ga]Ga-PSMA-11, followed by [¹⁸F]PSMA-1007 within 4 weeks. Fasting was required for four hours prior to the [¹⁸F]PSMA-1007 scan but there was no fasting requirement for [⁶⁸Ga]Ga-PSMA-11. Patients were administered either 100-150 MBq of [⁶⁸Ga]Ga-PSMA-11 45-60 minutes prior to imaging or 250MBq of [¹⁸F]PSMA-1007 120-180 minutes prior to imaging. All patients were asked to drink approximately 500mL of water after tracer administration and voided immediately prior to the scan. Iodinated contrast was not used. All scanning parameters for [⁶⁸Ga]Ga-PSMA-11 and [¹⁸F]PSMA-1007 scans were identical. Free breathing PET scans from skull vertex to mid-thigh were acquired using Siemens mCT Biograph PET/CT Scanners (Siemens Healthineers, Germany). Low Dose CT acquisition

was performed using automatic current modulation and 120kVp with image reconstruction to a slice thickness of 3mm. CT attenuation corrected PET images were reconstructed using an iterative algorithm with Time of Flight, Point Spread Function, Scatter and Random correction (Ultra HD), producing PET images with a matrix size of 200x200, pixel size of 4mm, slice thickness of 3mm and with a post reconstruction Gaussian filter of 5mm. Time per bed was 4 minutes over the pelvis, followed by 2.5 minutes per bed for the remainder of the scan range. The same reconstruction parameters were used for both radiotracers.

Image Analysis

Each scan was de-identified and independently reported by two Nuclear Medicine specialists experienced in the interpretation of PSMA PET studies. Reporting specialists were provided with a brief clinical history including radiotracer, indication, age, PSA, Gleason score and prior treatment and were blinded to other imaging reports. A standardised TNM reporting template according to the American Joint Committee on Cancer (AJCC) prognostic stage groups was used(20). Any discordant scan results underwent blinded evaluation by a third reader. Images were reviewed on a computer assisted reading application (Syngo.via, version VB30, Siemens Healthineers) enabling the review of PET, CT and fused imaging data in axial, sagittal and coronal planes. Maximum standardized uptake value (SUVmax) was recorded as it is considered operator-independent and suitable for small lesions. Known pitfalls in reporting of PSMA-ligand PET studies were considered. Scans were reported out of chronological order, with at least a six-week delay between reporting the complementary scans from the same patient (ie [⁶⁸Ga]Ga-PSMA-11 and [¹⁸F]PSMA-1007 PET/CT were reported independently). Separately, comparative quantitative analysis of uptake within lesions and physiologic tissue for each tracer was performed by one experienced reader. SUVmax was used for small lesions (prostate primary, and up to 3 most avid nodal and distant metastases per patient; and left sided stellate / coeliac / sacral ganglia, left parotid gland and left inguinal node) and SUVmean using a standardised 1cm³ sphere for larger physiologic organs (urinary bladder, liver and spleen). Clinical follow-up was performed for discordant findings and where possible was resolved by a multidisciplinary panel considering histopathology, appropriate additional imaging modality and/or PSA response in the appropriate clinical context (see Supplementary table).

Statistical Analysis

STATA 15 was used for analysis. Data were presented as mean and standard deviation (SD), median and interquartile range (IQR) or frequency and percent as appropriate. For SUVmean and SUVmax, differences between [¹⁸F]PSMA-1007 and [⁶⁸Ga]Ga-PSMA-11 paired measurements were examined using paired t-tests. Alternatively a Wilcoxon signed rank test was used if the assumptions of the paired t-test did not hold. Statistical significance was defined as a p-value less than 0.05 (two-sided).

Results:

The mean age of the 50 men participating in the study was 71.8 years (SD 6.7). The indication for [¹⁸F]PSMA-1007 PET/CT scans was initial staging (n=12), biochemical recurrence (n=27) and metastatic

disease evaluation (n=11). The majority of patient disease was International Society of Urological Pathology (ISUP) grade group 3 or higher. Median PSA value for staging, restaging and metastatic cohorts was 12ng/ml, 0.8ng/ml and 9.7ng/ml respectively. A minority of patients were treated with androgen deprivation therapy (28%) at the time of imaging. Patient characteristics are summarised in Table 1.

Significantly higher uptake at most sites of disease and physiologic organs (with the exception of bladder activity which was significantly lower) was observed for [¹⁸F]PSMA-1007 compared to [⁶⁸Ga]Ga-PSMA-11 (Table 2). The largest difference in SUVmax at disease sites was noted for local recurrence and nodal metastases. The absolute difference (although statistically significant) for bone metastases was relatively small, and too few visceral/adrenal metastases were identified for meaningful analysis. Similarly, [¹⁸F]PSMA-1007 demonstrated a significantly higher SUVmax within physiologic organs potentially confounding nodal assessment (eg. benign inguinal node, stellate / coeliac / sacral ganglia and parotid gland) and distant metastases (eg. liver, spleen). In contrast, bladder SUVmean was significantly lower with [¹⁸F]PSMA-1007 than [⁶⁸Ga]Ga-PSMA-11, relevant for detection of lesions adjacent the bladder and ureters. Background bone marrow avidity was assessed from a region of interest in the L2 vertebral body. [¹⁸F]PSMA-1007 had significantly higher bone marrow avidity (mean SUVmean of 1.5 (SD 0.5) vs 0.8 (SD 0.4), p < 0.001).

Local (T) staging concordance

Local (T) staging was assessed in 17 cases (12 staging and five metastatic cases with untreated primary), classified as PSMA PET stage T1/2 (intraprostatic uptake), T3a (extracapsular uptake), T3b (seminal vesicle invasion) or T4 (local invasion, including bladder & rectum). Findings were concordant in 12 cases, and in five cases [¹⁸F]PSMA-1007 scans resulted in a higher local stage, particularly identifying bladder wall invasion in three cases not apparent on [⁶⁸Ga]Ga-PSMA-11 (see Table 3a and Figure 1). Follow-up data confirmed three of the additional / discordant findings identified with [¹⁸F]PSMA-1007 were correct. The fourth case was reported T1/2 on [⁶⁸Ga]Ga-PSMA-11, T3b on [¹⁸F]PSMA-1007, but histopathology confirmed T3a disease. There was no relevant follow-up on the fifth discordant case. These additional findings did not impact the overall stage group classification as these cases also had nodal or distant metastasis.

Local recurrence concordance

Local recurrence was assessed in 33 cases after treatment of primary prostate cancer, classified as nil, equivocal and local recurrence with or without invasion of adjacent structures (see Table 3b). Findings were concordant in 30 cases, with [¹⁸F]PSMA-1007 upstaging in three cases (identifying local recurrence in two cases; one of which was equivocal on [⁶⁸Ga]Ga-PSMA-11 and the other had local recurrence with invasion of bladder). Follow-up data suggests one discordant case of local recurrence with invasion identified by [¹⁸F]PSMA-1007 was correct, but that one case of local recurrence (equivocal on [⁶⁸Ga]Ga-PSMA-11) was likely false positive.

Nodal staging concordance

Fourteen cases were concordantly staged as regional node positive (see Table 3c). [¹⁸F]PSMA-1007 upstaged three cases to N1 (due to proximity to ureter, see Figure 2), and in one case identified an equivocal node (classified N0 on [⁶⁸Ga]Ga-PSMA-11). [⁶⁸Ga]Ga-PSMA-11 upstaged one patient to N1 (due to focal avidity). Available follow-up confirms that an equivocal node (NE) identified on [¹⁸F]PSMA-1007 was likely reactive, and two cases of discordant [¹⁸F]PSMA-1007 avid nodal disease (N1) were confirmed.

Distant metastasis staging

Non-regional nodes (M1a)

Non-regional nodes (M1a) were concordantly identified in three cases (see Table 3d).

Bone (M1b)

Bone metastases were identified in 13 cases (see Table 3e). Equivocal bone lesions were identified on [¹⁸F]PSMA-1007 in six patients which were not appreciable on [⁶⁸Ga]Ga-PSMA-11. These lesions were in ribs (n=3), clavicle (n=1), sternum (n=1) and vertebra (n=1), and were less avid than definite bone metastases. They were significantly more avid on [¹⁸F]PSMA-1007 with a median SUVmax of 6.2 (IQR 5.3 – 7.9) vs 2.4 (IQR 1.5 – 3) for [⁶⁸Ga]Ga-PSMA-11 (p = 0.028). Equivocal lesions were considered M0 for the purposes of overall stage grouping. During follow-up, one patient developed definite bone metastasis at this site (T11 vertebral endplate) after 13 months (see Figure 3), whilst additional investigations in the remaining five patients confirmed a benign aetiology.

Other sites (M1c)

One patient had concordant adrenal metastasis identified ([¹⁸F]PSMA-1007 SUVmax 40.4, [⁶⁸Ga]Ga-PSMA-11 SUVmax 36.2). One patient had a discordant bladder metastasis identified on [¹⁸F]PSMA-1007 (discrete intense focal uptake on contralateral side of bladder in a patient with very extensive osseous metastatic disease) not appreciable on [⁶⁸Ga]Ga-PSMA-11 due to intense bladder radiourine activity (see Figure 4), and a solitary adrenal metastasis. One patient had discordant adrenal metastasis identified on [⁶⁸Ga]Ga-PSMA-11 (SUVmax 17.8) but not identified on [¹⁸F]PSMA-1007 (SUVmax 20.6) due to adjacent similarly intense liver activity (see Figure 5). It was prospectively identified by one of the three nuclear medicine specialists, identified on retrospective review and was clinically known at time of referral (previously reported on diagnostic CT scan).

Overall AJCC prognostic stage group

The AJCC prognostic stage group was concordant in the majority of cases (46/50 patients, 92%) with discordance observed for four patients (see Table 3f). Three discordances were due to identification of regional lymph nodes ([¹⁸F]PSMA-1007 upstaged in two cases [confirmed N1], [⁶⁸Ga]Ga-PSMA-11 upstaged

in one case [no follow-up available]). One discordance was due to histopathologically confirmed right adrenal metastasis adjacent to intense liver activity on [¹⁸F]PSMA-1007.

Discussion:

This is the largest prospective intra-individual comparative study of [¹⁸F]PSMA-1007 vs [⁶⁸Ga]Ga-PSMA-11 for prostate cancer staging, evaluation at biochemical recurrence and assessment of metastatic disease. Importantly our findings demonstrate similar overall AJCC staging concordance in 92% of patients, with a few notable differences.

Significantly reduced urinary radiotracer excretion by [¹⁸F]PSMA-1007 improves the characterisation of disease adjacent the bladder (prostate upstaging in 5/17 patients, and prostate bed upstaging in 3/33 patients) and ureters (regional nodal disease upstaging in three patients) compared to [⁶⁸Ga]Ga-PSMA-11. In one case a discrete bladder wall metastasis was also only identified with [¹⁸F]PSMA-1007. In most cases this did not alter the overall stage of the disease because of additional identified sites of either nodal or distant metastases. However this information may still play an important role in pre-operative surgical planning, choice of treatment modality (radiotherapy may be preferred over exenterative surgery for T4 disease), guiding the extent of radiotherapy treatment (extension of local tumour volume delineation to cover adjacent infiltrated bladder, rectum and/or elective treatment of pelvic lymph nodes(21, 22), and the use of androgen deprivation therapy(23). These imaging findings are consistent with most literature, including a matched pair comparison of 240 scans with [¹⁸F]PSMA-1007 vs F-DCFPyl identified suspected prostate/prostatic fossa lesions in a higher proportion of [¹⁸F]PSMA-1007 scans, particularly for the indication of biochemical recurrence(24). Also in the setting of biochemical recurrence, [¹⁸F]PSMA-1007 has previously been shown to be at least as accurate as [⁶⁸Ga]Ga-PSMA-11(14, 15, 25). [¹⁸F]PSMA-1007 has also previously demonstrated accurate histopathologic correlation in eight patients for pelvic nodal disease in 18/19 pelvic nodes in eight patients, down to 1mm diameter(12). In contrast, a recent small pilot study by Ende et al. compared the performance of [⁶⁸Ga]Ga-PSMA-11 to [¹⁸F]PSMA-1007 in biochemical recurrence in 12 patients following radical prostatectomy(26). In that study three lesions were identified in the prostate fossa on [⁶⁸Ga]Ga-PSMA-11 alone, compared with just one on [¹⁸F]PSMA-1007.

There are other significant differences in physiologic tracer distribution, with all measured sites other than bladder demonstrating higher SUV on [¹⁸F]PSMA-1007. In particular for nodal characterisation, uptake was consistently slightly higher on [¹⁸F]PSMA-1007 than [⁶⁸Ga]Ga-PSMA-11 in sacral, coeliac and stellate ganglia and in benign inguinal nodes. Rauscher et al. previously raised concern about significantly increased number of benign lesions that could confound an inexperienced reader with ganglia and unspecific lymph nodes being most common. In our study, distant nodal assessment was concordant between both tracers in this series, precluding any misdiagnosis of coeliac or stellate ganglia. In the pelvis, nodal upstaging occurred in nodes adjacent to ureters in typical drainage pathways, with no additional lesions identified in a location attributable to presacral ganglia. Pathologic/concordantly avid nodal uptake was significantly higher on [¹⁸F]PSMA-1007 than [⁶⁸Ga]Ga-PSMA-11 (SUVmax 11.1 vs 8.7, p = 0.002), potentially aiding accurate diagnosis.

Liver uptake is significantly higher with [¹⁸F]PSMA-1007, contributing to the missed diagnosis of a solitary right adrenal metastasis adjacent similarly 'intense' liver activity. In clinical practice it is unlikely this would have been missed (it was previously reported on a clinical diagnostic CT and was prospectively identified by one reporter in the study) but nevertheless liver activity obscuring visceral metastases must be highlighted as a key potential pitfall of [¹⁸F]PSMA-1007 PET/CT, as reported by others (27).

Our study identified six equivocal bone lesions that were not identified on [⁶⁸Ga]Ga-PSMA-11, one of which ([¹⁸F]PSMA-1007 SUVmax 9.4) subsequently progressed and was confirmed a definite osseous metastasis. The remaining non-specific lesions ([¹⁸F]PSMA-1007 SUVmax range 3.1-7.9) were either confirmed benign or no follow-up was available. Non-specific/equivocal bone lesions are a recognised issue in reporting of [¹⁸F]PSMA-1007 PET/CT. Rauscher et al. reported that non-specific bone lesions were identified in 48% of 102 clinically matched patients imaged with [¹⁸F]PSMA-1007 PET/CT, compared to 15% of 102 patients imaged with [⁶⁸Ga]Ga-PSMA-11 PET/CT(28). Further, a recent intraindividual comparison of [¹⁸F]PSMA-1007 PET to one of three other prostate cancer PET tracers ([⁶⁸Ga]Ga-PSMA-11, [¹⁸F]DCFPyL, and [¹⁸F]JK-PSMA-7) identified 15 non-specific bone marrow foci on [¹⁸F]PSMA-1007 PET that were not identified with other tracers, none of which demonstrated a morphological correlate on CT and post-contrast MRI(19). Our unpublished data (under review) identified non-specific bone lesions (NSBL) – defined as equivocal uptake in bone without an anatomic correlate on co-registered CT – in 94/214 (43.9%) of patients imaged with [¹⁸F]PSMA-1007. In 77 of these patients with clinical follow-up (median 15.8 months), none met predefined criteria for a definite or likely bone metastasis. There was no statistical difference in clinical risk or PSA levels for patients with / without an isolated NSBL. When compared to a cohort of definite bone metastases, an SUVmax cut-point of <7.2 (in the absence of typical features on CT) maximised the sensitivity and specificity and is a proposed threshold to exclude bone metastasis. NSBL with SUVmax 7.2-11.1 may be classified as equivocal or metastatic, with patient clinical risk factors, scan appearance and potential management implications used to guide interpretation. Using this classification, 4/6 patients with NSBL would have been dismissed as benign (SUVmax 3.1-6.5), and two patients with NSBL would have remained equivocal (SUVmax 7.9 in left 5th rib, and SUVmax 9.4 in T11 vertebral endplate), with the latter most avid lesion being subsequently confirmed malignant during follow-up. By comparison, confirmed [¹⁸F]PSMA-1007 avid bone metastases in our series demonstrated much higher uptake (median SUVmax 30.9 [IQR 20.8-41.5]).

A strength of our study is its prospective intraindividual study design, enabling definitive comparison of both [¹⁸F]PSMA-1007 and [⁶⁸Ga]Ga-PSMA-11 uptake within the same lesions / patient. Most other studies evaluating [¹⁸F]PSMA-1007 have been retrospective matched pair comparisons, retrospective single tracer or small pilot studies. Furthermore our blinded analysis by two independent nuclear medicine specialists (blinded to the other scan, reporter, and other imaging results), with use of an independent third reviewer in case of discordant staging, is a rigorous study design. Limitations of the study include the lack of a definitive gold standard, given the impracticality of taking a biopsy of every avid lesion. Concordant findings were considered true positive, but there is a limitation on evaluation of discordant findings beyond the results from available clinical follow-up.

Conclusion:

This large prospective intraindividual comparison of [¹⁸F]PSMA-1007 PET/CT vs [⁶⁸Ga]Ga-PSMA-11 PET/CT has demonstrated overall high concordance (92%) for TNM stage in the context of prostate cancer primary staging, biochemical recurrence and evaluation of patients with metastatic disease. Reduced [¹⁸F]PSMA-1007 urinary radiotracer excretion improves characterisation of disease adjacent the bladder (prostate or prostate bed following definitive treatment, including local invasion) and ureters (peri-ureteric nodes) compared to [⁶⁸Ga]Ga-PSMA-11. [¹⁸F]PSMA-1007 demonstrates significantly higher uptake within involved nodes and bone metastases, and physiologic tissues including liver, spleen, neural ganglia, bone marrow and benign nodes. Inexperienced reporters of [¹⁸F]PSMA-1007 PET should understand that hepatic uptake may obscure metastases within the liver or adjacent adrenal gland, and that [¹⁸F]PSMA-1007 is associated with more equivocal bone lesions. Both tracers are acceptable for imaging of prostate cancer, with factors influencing choice including availability (local generator production of [⁶⁸Ga]Ga-PSMA-11 vs external cyclotron supply [¹⁸F]PSMA-1007), preference for improved characterisation of disease in the prostate and pelvic nodes (favouring [¹⁸F]PSMA-1007) versus likelihood of visceral metastasis (favouring [⁶⁸Ga]Ga-PSMA-11) and the experience of reporting specialists to exclude benign patterns of uptake, particularly neural ganglia and equivocal bone lesions.

Declarations:

Funding: No funding was received for conducting this study. Matthew J Roberts is supported by a Clinician Research Fellowship from the Metro North Office of Research, Queensland Health, and a Doctor in Training Research Scholarship from Avant Mutual Group Pty Ltd.

Conflicts of interest / Competing interests: The authors have no conflicts of interest to declare that are relevant to the content of this article.

Availability of data and material: Available upon reasonable request.

Code availability: not applicable.

Ethics approval and consent to participate: This trial was approved by the institutional review board of the Royal Brisbane and Women's Hospital Human Research Ethics Committee and was conducted in accordance with 1964 Helsinki Declaration. Written informed consent for participation and publication was provided.

Author contributions: All authors contributed to the study conception and design, or acquiring data, or analysing and interpreting data. Material preparation, data collection and analysis were performed by Maciej Debowski, Brooke Gulhane, Evyn Arnfield, David Pattison, Stuart Ramsay and Paul Thomas. The first draft of the manuscript was written by David Pattison and all authors commented on previous versions of the manuscript. All authors read and approved the final manuscript.

ACKNOWLEDGMENTS:

We would like to acknowledge the effort of nuclear medicine technologists, nursing and medical staff at Royal Brisbane and Women's Hospital and Q-TRaCE (QLD – The Radiopharmaceutical Centre of Excellence) radiochemistry staff who supported and contributed to the running of this trial, in addition to the enthusiastic participation of our patients. We are also grateful to Marita Prior for assistance with trial administration.

AJCC, AJCC prognostic stage group; F/U, follow-up; N/A, not available; TURP, transurethral resection of the prostate; RT, radiotherapy; (F), consistent with [¹⁸F]PSMA-1007; (Ga), consistent with [⁶⁸Ga]Ga-PSMA-11; RT,

radiotherapy; LR, local recurrence; LRe, local recurrence-equivocal; LRI, local recurrence with invasion adjacent organs; Nil, nil local recurrence; Ne, Nodes equivocal; Me, equivocal bone metastasis

Figures

Figure 1

[¹⁸F]PSMA-1007 clearly identifies bladder invasion (T4, orange arrows), not visible on [⁶⁸Ga]Ga-PSMA-11 due to intense urinary radiotracer excretion. Images left to right, sagittal PET, sagittal fused PET/CT and sagittal CT; SUV window threshold 0-10.

Figure 2

[18F]PSMA-1007 identified two discrete pelvic side wall nodes adjacent to surgical clips (orange arrows), which were considered pooling of urinary radiotracer on [68Ga]Ga-PSMA-11 (red arrows). Followup [18F]PSMA-1007 performed 13 months later confirmed definite progressive nodal disease at this site (blue arrows). Images left to right, maximum intensity projection, sagittal PET and sagittal fused PET/CT images; SUV window threshold 0-10.

Figure 3

[18F]PSMA-1007 demonstrated focal uptake at the inferior endplate of T11 vertebra associated with sclerosis (orange arrows), considered equivocal given the atypical appearance of this solitary lesion. There was no significant uptake at this site on [68Ga]Ga-PSMA-11PET/CT (red arrows). Subsequent followup [18F]PSMA-1007 PET/CT confirmed increasing uptake and sclerosis at this site, and additional FPSMA avid osseous lesions consistent with progressive metastatic disease (blue arrows). Images left to right, sagittal PET, sagittal fused PET/CT and sagittal CT; SUV window threshold 0-10.

Figure 4

[^{18}F]PSMA-1007 clearly identifies a discrete separate focus of bladder uptake consistent with visceral metastasis (M1c, orange arrow), not visible on [^{68}Ga]Ga-PSMA-11 due to intense urinary radiotracer excretion. Images left to right, axial PET, axial fused PET/CT and axial CT; SUV window threshold 0-10.

Figure 5

Intensely [^{18}F]PSMA-1007 avid right adrenal metastasis (orange arrow) was not identified due to similarly intense physiologic uptake in the adjacent liver. This lesion was prospective identified on [^{68}Ga]Ga-PSMA-11 PET/CT (red arrow), and subsequently histopathologically confirmed as metastatic prostate carcinoma. Images left to right, axial PET, axial fused PET/CT and axial CT; SUV window threshold 0-10.
