## 20 **ABSTRACT**

21 The discovery of nanozymes for selective fragmentation of proteins would boost  
22 the emerging areas of modern proteomics, however, the development of  
23 efficient and reusable artificial catalysts for peptide bond hydrolysis is  
24 challenging. Here we report the detailed catalytic properties of a microporous  
25 zirconium carboxylate metal-organic framework, MIP-201, in promoting peptide  
26 bond hydrolysis in a simple dipeptide, as well as in horse-heart myoglobin (Mb)  
27 protein that consists of 153 amino acids. We demonstrate that MIP-201 features  
28 an excellent catalytic activity and selectivity, a good tolerance toward reaction  
29 conditions covering a wide range of different pH values, and importantly, an  
30 exceptional recycling ability associated with easy regeneration process. Taking  
31 into account the excellent catalytic performance of MIP-201 and its other  
32 advantages such as 6-connected  $Zr_6$  cluster active sites, the green, scalable  
33 and cost-effective synthesis, and an outstanding chemical and architectural  
34 stability, our finding suggests that MIP-201 may be a promising and practical  
35 alternative to the current commercially available catalysts for peptide bond  
36 hydrolysis.

37

38

39

40

## 41 INTRODUCTION

42 Peptide bond is a type of robust amide bond that connects amino acid residues  
43 in proteins, and thus it has essential importance in biological systems. The  
44 remarkable stability of peptide bond under physiological conditions (with an  
45 estimated half-life of 350-600 years at 25 °C in neutral pH conditions)  
46 guarantees the intactness of the primary sequence of a protein, but results in a  
47 considerable challenge when there is a need to break the bond<sup>1</sup>.

48 Catalytic hydrolysis is an efficient way of breaking peptide bond, which results  
49 in the release of the carboxylic and amine functional groups. In biological  
50 systems this reaction is carried out by enzymes with extremely high reaction  
51 rates. However, outside biological systems, the hydrolysis of proteins is also an  
52 important procedure in areas such as protein structure analysis, protein  
53 engineering and protein-cleaving drug design<sup>2, 3, 4</sup>. Therefore, the high costs  
54 and the extreme sensitivity of enzymes to the reaction conditions motivated the  
55 development of artificial proteases<sup>2, 3</sup>. The main goal in developing artificial  
56 proteases is to achieve adequate reactivity and specificity, as it is very  
57 challenging for artificial catalysts to match the exceptional catalytic power of  
58 natural enzymes.

59 Among existing alternatives, homogeneous catalysts based on Lewis acid  
60 metal salts often suffer from formation of gels at neutral and basic conditions,  
61 leading to loss of reactivity and difficulties in the separation of products and

62 reactants<sup>5</sup>. In comparison, metal complexes prevent the formation of gels  
63 during catalysis, but have other shortcomings, such as limited reactivity window,  
64 toxicity and poor recyclability<sup>2, 5</sup>. More recently metal-substituted  
65 polyoxometalate (POM) clusters were developed as homogeneous catalysts for  
66 peptide bond hydrolysis. In particular, zirconium(IV)-substituted POMs have  
67 been reported to achieve an encouraging combination of activity and selectivity  
68 in mildly acidic and neutral media<sup>6, 7, 8</sup>. But the structural dynamic of Zr-  
69 substituted POMs under the reaction conditions and their high solubility make  
70 the catalyst recycling and product purification problematic. In order to  
71 circumvent these shortcomings, insoluble Zr<sub>6</sub>-oxo cluster-based metal-organic  
72 framework (MOF) were evaluated as the state-of-the-art heterogeneous  
73 catalyst for accelerating peptide bond hydrolysis<sup>5, 9, 10</sup>. The large-pore MOF-808  
74 and NU-1000 (NU, Northwestern University) displayed much better reactivity  
75 and recyclability compared to POMs under neutral and mildly acidic conditions,  
76 but still suffer from limited stability under alkaline reaction conditions<sup>11, 12</sup>. The  
77 highly defective UiO-66 (UiO, University of Oslo) and its functional derivatives,  
78 on the other hand, showed comparable catalytic performance with POMs but  
79 with improved stability under neutral and mildly alkaline conditions. Therefore,  
80 it still remains a great challenge to develop an efficient heterogeneous catalyst  
81 that is effective under various conditions and within a wide range of pH values,  
82 while preserving a good catalytic activity and specificity for the catalytic peptide  
83 bond hydrolysis.

84 Herein, we present the first Zr-MOF with square-octahedron (**soc**) topological  
85 net constructed from Zr<sub>6</sub>-oxo cluster secondary building units (SBUs) and a  
86 tetracarboxylate linker (3,3',5,5'-tetracarboxydiphenylmethane (H<sub>4</sub>mdip)),  
87 denoted as MIP-201 (MIP, Materials of the Institute of Porous Materials from  
88 Paris), that addresses the challenge of developing highly efficient and robust  
89 heterogeneous catalyst for peptide bond hydrolysis. MIP-201 possesses  
90 catalytically active 6-connected Zr<sub>6</sub>-oxo cluster building units in its robust  
91 microporous network, which leads to excellent heterogeneous catalytic  
92 performance in accelerating peptide bond hydrolysis under a wide pH range of  
93 condition (acidic, neutral and basic), a good catalytic activity and selectivity, and  
94 a superior catalyst recycling ability. The combined advantage of its catalysis  
95 performance, along with its cost-efficient, green and scalable synthesis, and an  
96 excellent architectural and chemical stability, make MIP-201 one of the most  
97 promising artificial proteases discovered so far.

## 98 **RESULTS**

99 **Synthesis and crystal structure of MIP-201.** Zr<sub>6</sub>-oxo cluster is the dominant  
100 building unit in the fabrication of Zr-carboxylate MOFs. The connection numbers  
101 of Zr<sub>6</sub>-oxo clusters cover a wide range of 12, 10, 9, 8, 6, 5 and 4 in the reported  
102 examples, showing an extraordinary flexibility in connecting various linkers to  
103 generate a large library of different structures<sup>13, 14, 15, 16</sup>. While the stabilities of  
104 Zr-MOFs constructed with low connection-number (5, and 4) nodes are still  
105 under debate<sup>15, 16, 17, 18</sup>, 6-connection is likely the limit to keep the material

106 stability at an acceptable level toward certain applications<sup>19, 20, 21</sup>. In a sharp  
107 contrast to the large number of Zr-MOFs based on high connection-number  
108 (above 8 till 12) building units, only six compounds are constructed from 6-  
109 connected Zr<sub>6</sub>-oxo clusters, including PCN-224<sup>22</sup>, PCN-777<sup>23</sup> (PCN, Porous  
110 Coordination Network), UMCM-309<sup>24</sup> (UMCM, University of Michigan  
111 Crystalline Material), the interpenetrated Zr-BTB<sup>25</sup>, MOF-808<sup>19</sup> and BUT-108  
112 (BUT, Beijing University of Technology)<sup>26</sup>.

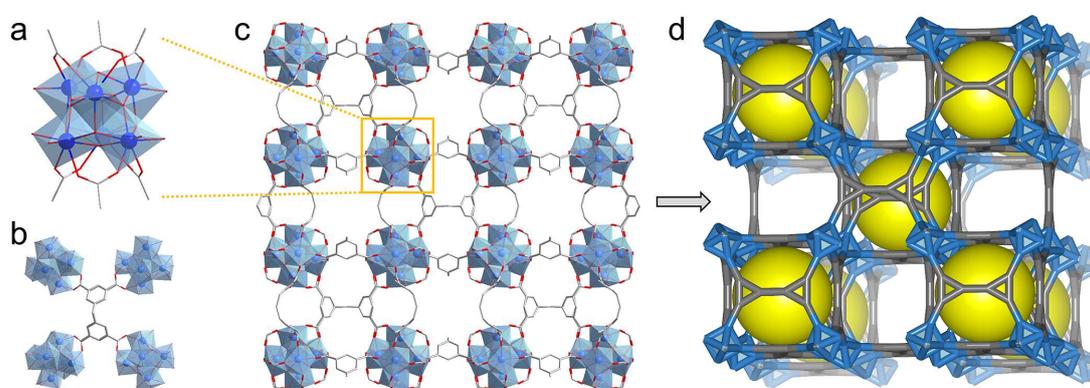

113 In those structures, the 6-connected Zr<sub>6</sub>-oxo cluster shows two different  
114 configuration modes, namely the hexagonal planar and trigonal prismatic. The  
115 hexagonal planar configuration was only observed in PCN-224 while the other  
116 five examples all share the trigonal prismatic one. The trigonal prismatic  
117 configuration of the 6-connected Zr<sub>6</sub>-oxo cluster is of a particular interest for the  
118 design of new topological structure of Zr-MOFs<sup>27</sup>, since it has been proven that  
119 it could function similarly as the trimer building units of trivalent metal ions in  
120 the MOF framework fabrication, such as the case of PCN-777 to be related to  
121 the metal oxo-trimer-based MIL-100 and MIL-101 (MIL, Materials of Institut  
122 Lavoisier)<sup>23</sup>.

123 In this regard, we have analyzed the possibility of replacing trivalent metal  
124 trimer SBUs by 6-connected Zr<sub>6</sub>-oxo clusters in several types of known MOF  
125 structures, including MIL-88<sup>28</sup>, soc-MOFs<sup>29</sup> and series of PCN networks<sup>30</sup>. It  
126 turned out that the **soc** topological net would be one of the most feasible targets  
127 to achieve as detailed below: 1) all the connection sites on the trimer node are

128 occupied by the carboxylate groups from the tetracarboxylate linker molecules,  
129 leading to the same configuration of the trigonal prismatic 6-connected Zr<sub>6</sub>-oxo  
130 cluster; 2) the special shape of the tetracarboxylate linkers with appropriate  
131 steric hindrance and the separation between carboxylate groups could  
132 efficiently force the linkage and structure extending in the way of generating  
133 **soc** net; 3) reported **soc**-MOFs displayed excellent stability even with trivalent  
134 metal ions probably due to the hydrophobicity of the structural frameworks as  
135 well as the considerable steric hindrance around the SBU to weaken the attack  
136 from water molecules<sup>31, 32</sup>. Regarding the selection of linker for this hypothesis,  
137 a tetracarboxylate ligand with an appropriate structural flexibility would be even  
138 beneficial if the larger size and elevated rigidity of Zr<sub>6</sub>-oxo cluster are taken into  
139 consideration in comparison with that of trivalent trimers. To that end, H<sub>4</sub>mdip  
140 was finally selected as the most suitable tetracarboxylate linker for the  
141 synthesis of **soc**-Zr-MOF, not only due to its cost-effective and scalable  
142 synthesis, but also as its good structural flexibility to adapt various connection  
143 environments in the MOF construction is well documented<sup>33, 34</sup>.

144 Following the aforementioned guidance, a highly crystalline product (MIP-201)  
145 could be isolated from the solvothermal reaction of ZrCl<sub>4</sub> and H<sub>4</sub>mdip in pure  
146 acetic acid at 120 °C. Several attempts to obtain larger product particle suitable  
147 for single crystal X-ray diffraction data collection, including the combination of  
148 different Zr(IV) precursors with various solvent mixtures (formic acid, acetic  
149 anhydride, water, ethanol, etc.), did not lead to any increase in size of the

150 product (Supplementary Fig. 1). In addition, the good tolerance of MIP-201  
151 toward the synthesis conditions allows the development of green and scalable  
152 routes for further practical applications. After optimization, an all-green reaction  
153 of refluxing non-corrosive  $\text{Zr}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$  and  $\text{H}_4\text{mdip}$  in the mixture of water  
154 and acetic acid under ambient pressure was set for the scale-up synthesis of  
155 MIP-201 product at the 10 g scale associated with a good yield (90% based on  
156 the linker used).

158 **Fig.1 | Crystal structure of MIP-201.** **a**, The 6-connected  $\text{Zr}_6$ -oxo cluster building unit with the  
159 trigonal prismatic configuration. **b**, One tetracarboxylate linker molecule connects the adjacent  
160 four  $\text{Zr}_6$ -oxo clusters. **c**, The overall structure viewed along the c-axis. **d**, The **soc** topological  
161 net of MIP-201 structure (Zr in blue, C in gray, O in red, and the yellow ball stands for the cavity).

162 The crystal structure of MIP-201 was solved by a combined analysis of high-  
163 resolution powder X-ray diffraction (PXRD) data and a computational topology-  
164 guided reverse engineering approach (Supplementary Figs. 2 and 3,  
165 Supplementary Table 1). MIP-201 with a formula of  $[\text{Zr}_6(\mu_3\text{-O})_4(\mu_3\text{-OH})_4(\text{acetate})_{0.24}(\text{OH})_{5.76}(\text{H}_2\text{O})_{5.76}(\text{mdip})_{1.5}]$ ,  
166 was found to crystallize in a cubic  
167  $I\bar{m}\text{-}3$  space group (No. 204) with unit cell parameters of  $a = 24.5847(11)$  Å and

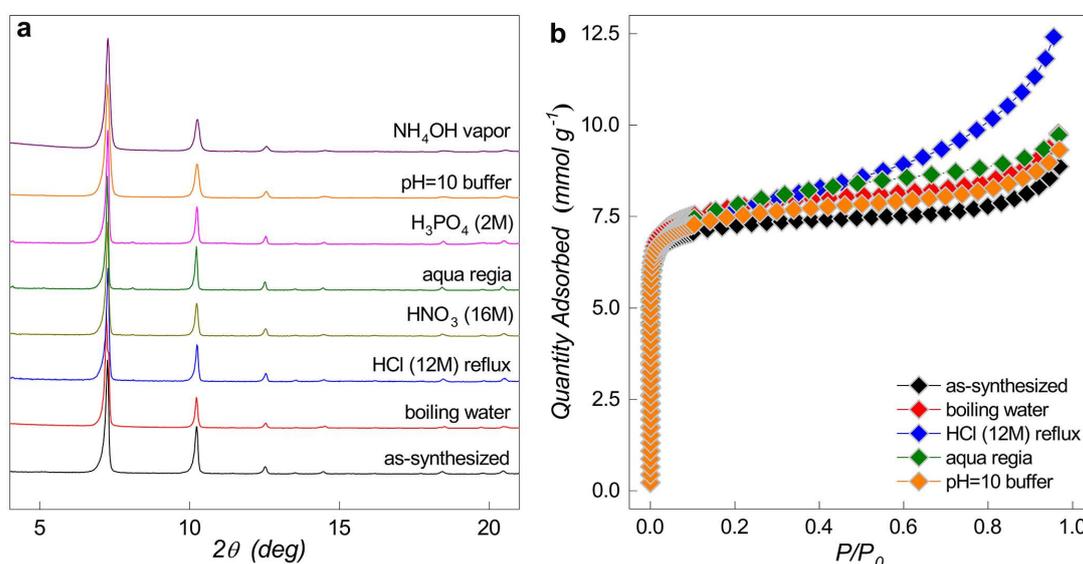

168  $V = 14859.2(11) \text{ \AA}^3$ . It features a three-dimensional (3D) microporous  
169 framework composed of 6-connected  $\text{Zr}_6(\mu_3\text{-O})_4(\mu_3\text{-OH})_4$  oxo-cluster SBUs with  
170 mdip tetratopic linker molecules separating and spacing. As shown in Fig. 1a,  
171 each  $\text{Zr}_6$  oxo-cluster SBU comprises six carboxylate groups from six different  
172 linker molecules at the polar positions and six terminal acetate groups or -  
173 OH/ $\text{H}_2\text{O}$  pairs locating around the equatorial plane. Taking account of the  
174 molecular conformation character of mdip over the other rigid tetratopic linkers,  
175 the considerable flexibility of the methylene group that connects two benzene  
176 rings plays an important role in this case by forcing the mdip molecule to adapt  
177 this connection mode (Fig. 1b). MIP-201 represents, to our knowledge, the first  
178 example of this type of 6-connected  $\text{Zr}_6$  cluster SBU in Zr-MOFs built with  
179 tetratopic linkers.

180 The four carboxylate groups of mdip linker are fully deprotonated to connect  
181 eight separated Zr(IV) ions binding four adjacent SBUs together (Fig. 1b). As a  
182 result of the high flexibility of the methylene group, mdip molecules are able to  
183 adjust their length and width according to the corresponding connection  
184 requirements, and thus realize the interconnection of eight neighboring SBUs,  
185 giving rise to a distorted cubic pocket with a free diameter around 6 Å. However,  
186 the windows size of the pocket is too small (2.4 Å) to be accessible for guest  
187 molecules. There are however free voids generated between the neighboring  
188 pockets showing an accessible dimension of around 10 Å×12 Å, leading to a  
189 theoretical nitrogen-accessible surface area of 1040  $\text{m}^2 \text{g}^{-1}$  and a total free pore

190 volume of  $0.47 \text{ cm}^3 \text{ g}^{-1}$  calculated from the crystal structure (Supplementary Fig.  
191 4). However, residual  $\text{SO}_4^{2-}$  groups are still trapped inside the pore of the MOF  
192 ( $\text{S/Zr}=27.6/72.4$ , atomic ratio), as evidenced by scanning electron microscopy  
193 with energy-dispersive X-ray spectroscopy (SEM-EDX) measurement, which  
194 results in an experimental Brunauer-Emmett-Teller (BET) area of  $680 \text{ m}^2 \text{ g}^{-1}$   
195 and a total pore volume of  $0.30 \text{ cm}^3 \text{ g}^{-1}$  deduced from nitrogen porosimetry,  
196 slightly below the theoretical values. The similar observation of strongly trapped  
197  $\text{Cl}^-$  species in the MOF pore was found when  $\text{ZrCl}_4$  or  $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$  were used  
198 as the reactants for the synthesis of MIP-201, which has been recognized as a  
199 general issue for the fully activation of Zr-MOFs. The overall 3D structure of  
200 MIP-201 is fabricated through the cubic pockets packing to each other  
201 separated perfectly with the free void spaces (Fig. 1c), thus displays a typical  
202 network of *cdj* topology. It is worthy to note that MIP-201 is, to our knowledge,  
203 the first example of **soc** type network in Zr-MOFs (Fig. 1d).

204 **Stability of MIP-201.** In order to ensure the potential of MIP-201 in various  
205 applications, thermal and chemical stability tests under different conditions  
206 were carried out. Temperature-dependent PXRD and thermogravimetric  
207 analysis (TGA) data (Supplementary Figs. 5 and 6) indicate that MIP-201  
208 maintains its crystal structure up to  $375 \text{ }^\circ\text{C}$ , which is adequate for most of the  
209 applications related. Chemical resistance of MIP-201 has been checked under  
210 diverse conditions, including boiling water, fuming acid, super-acid, and basic  
211 conditions. As shown in Fig. 2a, the long-range order of the MIP-201 structure

212 was maintained very well under all the tested conditions supported by their  
213 almost identical PXRD patterns. Long duration contacts with boiling water,  
214 fuming acids, aqua regia, highly concentrated  $\text{H}_3\text{PO}_4$  and basic conditions  
215 (pH=10 buffer and  $\text{NH}_4\text{OH}$  vapor) did not show notable degradation of the  
216 crystalline structure of MIP-201. Nitrogen sorption measurements at 77 K  
217 carried out on samples treated with some extremely harsh conditions supported  
218 the good reservation of the MOF long-range order and porosity (Fig. 2b),  
219 despite of structural defects were generated in some cases such as HCl or aqua  
220 regia treatments. Therefore, MIP-201 displays excellent stability for  
221 applications, especially in a regard of bio-related applications, which generally  
222 requires a good tolerance toward the presence of phosphate species.

223

224 **Fig. 2 | Chemical stability of MIP-201.** **a**, PXRD patterns ( $\lambda_{\text{Cu}} \approx 1.5406 \text{ \AA}$ ) of MIP-201  
225 samples treated under various chemical conditions. **b**, Nitrogen adsorption isotherms of MIP-  
226 201 samples after some typical chemical treatments collected at 77K (samples were refluxed  
227 in water before thermal activation at  $120^\circ\text{C}$  for each condition).

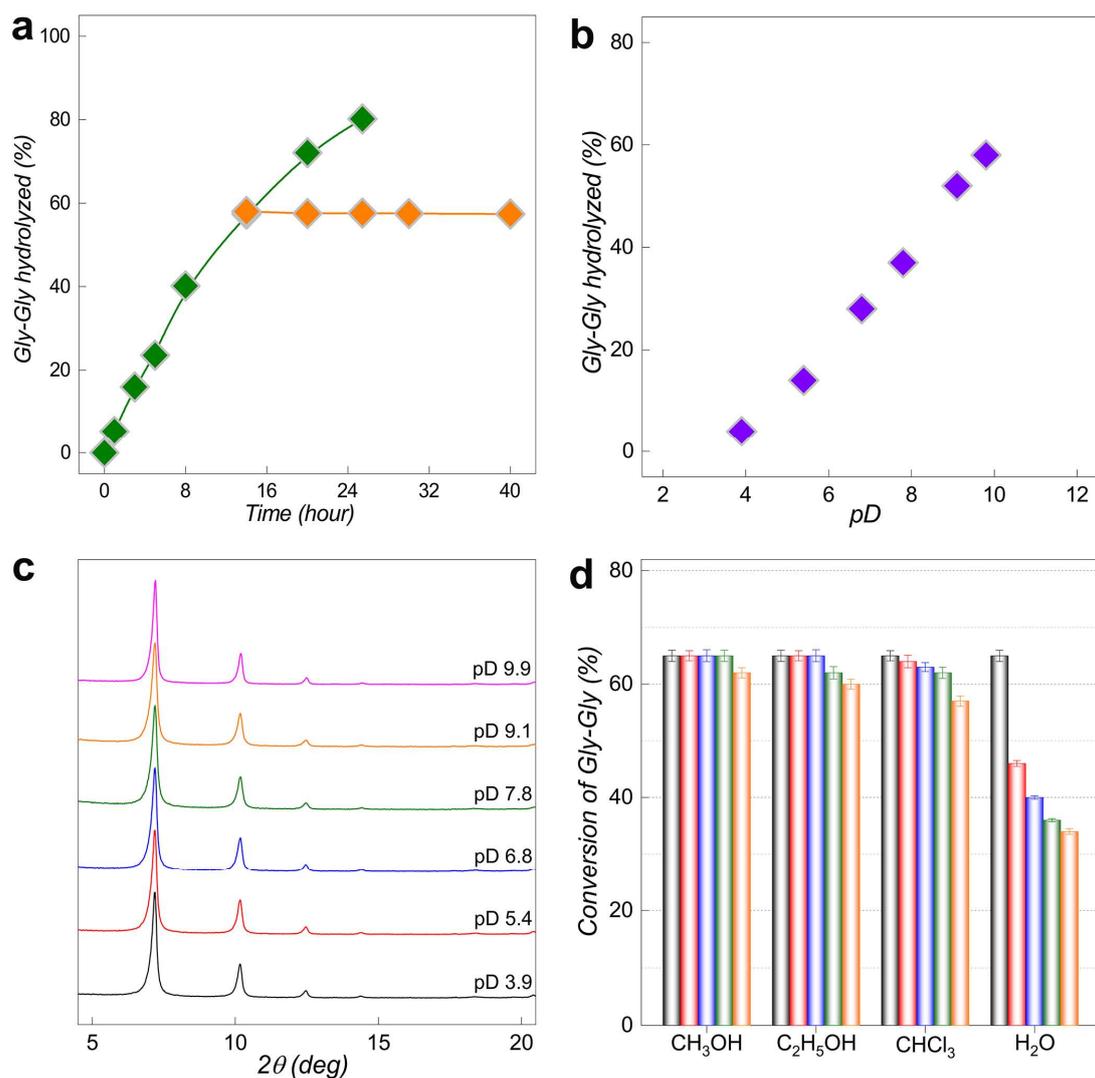

## 228 **Catalytic performance of MIP-201 in promoting peptide bond hydrolysis**

229 The initial evaluation of the **MIP-201** catalytic performance towards peptide  
230 bond hydrolysis was tested using a simple Gly-Gly dipeptide. A mixture of  
231 equimolar amounts (2.0  $\mu\text{mol}$ ) of Gly-Gly and MIP-201 was incubated at 60 °C  
232 and pD 7.4 (Supplementary Fig. 7). and the progress of peptide bond hydrolysis  
233 was followed by  $^1\text{H}$  NMR spectroscopy (Supplementary Fig. 8 and 9). To  
234 confirm that the catalytic activity was due to the MIP-201 material, and was not  
235 caused by Zr(IV) ions leached in solution, the MIP-201 powder was removed  
236 from the reaction mixture after 14 hours by centrifugation, and the  
237 homogeneous solution was allowed to react further. As it can be seen from Fig.  
238 3a, no additional Gly-Gly hydrolysis was observed after removing MIP-201 from  
239 the reaction mixture, indicating that the peptide bond hydrolysis is exclusively  
240 associated with catalytically active sites in the solid MIP-201 material, and is  
241 not caused by Zr(IV) ions or Zr<sub>6</sub>-oxo clusters that might have leached into  
242 solution.

243 The rate constant of Gly-Gly hydrolysis ( $k_{\text{obsd}}$ ) catalyzed by MIP-201 was  
244 calculated to be  $1.85 \times 10^{-5} \text{ s}^{-1}$  (corresponding to  $t_{1/2} = 10.4 \text{ h}$ ) at 60 °C and pD  
245 7.4 (Supplementary Fig. 8), which represents an enhancement of nearly two  
246 orders of magnitude compared to the reactions catalyzed by Zr(IV)-POMs  
247 under the same experimental conditions<sup>6, 7</sup>, and a 2500 times enhancement  
248 compared to the un-catalyzed hydrolysis of Gly-Gly ( $k_{\text{obsd}} = 7.4 \times 10^{-9} \text{ s}^{-1}$ ,  
249 corresponding to  $t_{1/2} = 3 \text{ years}$ ). It is noteworthy that the rate of Gly-Gly

250 hydrolysis by MIP-201 is comparable to that previously observed with MOF-808,  
251 when the larger surface area of MOF-808, which allows for more adsorption of  
252 peptide substrate, is taken into consideration (Supplementary Fig. 10).  
253 Furthermore, NU-1000, which has mesoporous cavities associated with a large  
254 BET area ( $2200 \text{ m}^2 \text{ g}^{-1}$ ) but is constructed from 8-connected  $\text{Zr}_6$ -oxo SBUs,  
255 showed a peptide bond hydrolysis rate which was more than one order of  
256 magnitude slower than that of MIP-201. This highlights the important role of 6-  
257 connection of the  $\text{Zr}_6$ -oxo node on the catalytic activity, and the fact that the  
258 active site density is critical for the efficiency of a MOF as artificial peptidase.  
259 Interestingly, the hydrolysis of amide bond in N-Methylacetamide by MIP-201  
260 was not observed after 8 days of reaction (Supplementary Fig. 11), supporting  
261 the fact that the C-terminal carboxyl group plays an important role in  
262 acceleration of the reaction, possibly by enabling binding of the dipeptide to the  
263 catalytically active Zr(IV) sites.

264 The catalytic hydrolysis of peptide bond was further investigated as a function  
265 of pD. The mixture of Gly-Gly and MIP-201 were incubated at  $60 \text{ }^\circ\text{C}$  in solutions  
266 with pH ranging from 3.9 to 9.9 and the corresponding results are presented in  
267 Fig. 3b. In the range from acidic to neutral pD, the rate enhancement was  
268 observed along with the pD increase. Similar evolution was observed in other  
269 catalytic systems, and was explained by the gradual reduction of Gly-Gly  
270 protonation which facilitates the effective binding to the catalytically active metal  
271 ion centers<sup>2</sup>. Remarkably, with further pD increase, a very distinct catalytic

272

273 **Fig. 3 | Catalytic performance of MIP-201 for hydrolysis of Gly-Gly. a.** Hydrolysis of 2.0

274  $\mu\text{mol}$  of Gly-Gly in the presence of 2.0  $\mu\text{mol}$  of MIP-201 before ( $\blacklozenge$ ) and after ( $\blacklozenge$ ) the removal

275 of MIP-201 (pD 7.4 and 60 °C). **b.** Conversion of Gly-Gly after eight-hour hydrolysis of Gly-Gly

276 (2.0  $\mu\text{mol}$ ) catalyzed by MIP-201 (2.0  $\mu\text{mol}$ ) at 60 °C and different pD values. **c.** PXRD patterns

277 of MIP-201 after eight-hour catalysis at 60 °C in reaction solution of different pD values ( $\lambda_{\text{Cu}} \approx$

278 1.5406 Å). **d.** Conversion of Gly-Gly after sixteen hours at 60 °C in the presence of MIP-201 for

279 five reaction cycles. Different organic solvents were used to wash and exchange with water

280 before a four-hour activation at 120 °C.

281 performance of MIP-201 was observed, as the reaction rates displayed a

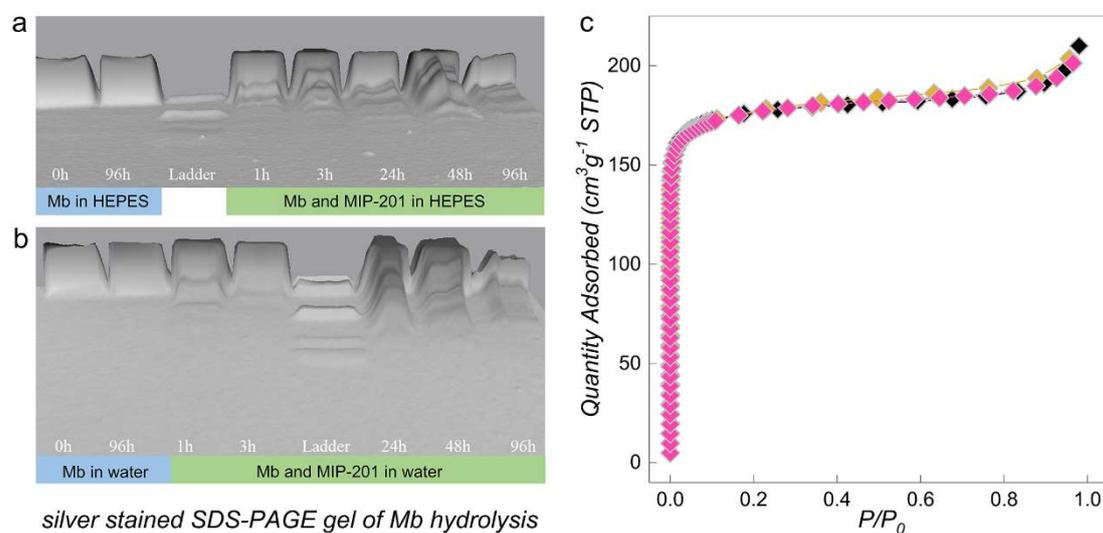

282 steady increase, with a more than 50% rate enhancement observed at pD=9.9  
283 compared to physiological pD. On the contrary, decrease in reaction rates has  
284 been reported for many other catalysts that were used under alkaline conditions,  
285 and were mainly attributed to the instability of the catalysts. For instance, metal  
286 salts typically form inactive insoluble gels or solids under mildly basic solutions<sup>5</sup>,  
287 while POMs are largely unstable under alkaline conditions and show the best  
288 catalytic efficiency in slightly acidic situations<sup>6, 7</sup>. Similarly, the PXRD patterns  
289 of both MOF-808 and NU-1000 revealed crystal structure degradation and  
290 reduced catalytic activities when the pD of the solution was raised above 8.0  
291 (Supplementary Fig.12)<sup>5, 9</sup>. On the contrary, the stability of MIP-201 within the  
292 full pD range of the reaction conditions was confirmed by PXRD (Fig. 3c) and  
293 IR spectroscopy (Supplementary Fig. 13) carried out on the MIP-201 samples  
294 collected after the completion of catalytic reaction. These characterizations  
295 indicated that the structure of MIP-201 remains intact with no evidence of  
296 degradation under all examined reaction conditions.

297 The recycling of MIP-201 as a heterogeneous peptidase was further  
298 investigated, revealing a remarkably high architectural stability after the direct  
299 regeneration by washing with water. Although a decrease of catalytic activity  
300 was observed for water-regenerated MIP-201, from 71% yield observed in the  
301 second run to 55% in the fourth run (Fig. 3d), it could be rationalized by the  
302 microporous nature of the MIP-201 structure, in which a partial pore blocking  
303 may lead to a slight reduction of the number of accessible catalytically active

304 sites. It is worth mentioning that comparable yields were observed in the fifth  
305 and fourth cycle, supporting the conclusion that the number of the accessible  
306 catalytic sites has approached an equilibrium while the overall architecture of  
307 the MIP-201 framework was maintained during the entire catalytic cycles. A  
308 similar observation was found when chloroform ( $\text{CHCl}_3$ ) was used to regenerate  
309 catalyst after the reaction, while both methanol and ethanol were shown to be  
310 excellent solvents for regenerating MIP-201, in accordance to recyclability  
311 studies with other MOFs in general<sup>5</sup>. In contrast to MIP-201, the recycling of  
312 MOF-808 after Gly-Gly hydrolysis indicated a limited architectural stability of  
313 the MOF-808 framework, which impeded its regeneration by direct water  
314 washing and exchanging. This was attributed to the combined effect of  
315 considerable structural defects present in MOF-808 and the high surface  
316 tension of water<sup>5, 11</sup>. This resulted in a drop of more than 90% in the second run  
317 of catalysis after washing with water, which was associated with a partial  
318 structural collapse of MOF-808 with the direct hydrolytic treatment.

319 **Hydrolysis of Horse-heart myoglobin (Mb) catalyzed by MIP-201.** As the  
320 high catalytic activity, good stability and recycling ability of MIP-201 were  
321 demonstrated in the hydrolysis of a model dipeptide, further evaluation of its  
322 catalytic performance was carried out on Horse-heart myoglobin (Mb), a protein  
323 containing 153 amino acids with approximate Mw of 16.95 kDa. Previous  
324 studies have shown that water soluble Zr(IV) substituted POMs<sup>35</sup> and insoluble  
325  $\text{Hf}_{18}$  metal-oxo cluster<sup>36</sup> were able to selectively hydrolyze Mb at peptide bonds

326 containing Asp residues. In that respect, Mb represents a good model protein  
327 for evaluating and comparing the catalytic potential of MIP-201 to other reported

329 **Fig.4 | Hydrolysis of Horse-heart myoglobin (Mb) catalyzed by MIP-201.** a. Silver stained  
330 SDS-PAGE gel of Mb hydrolysis in the presence of MIP-201 in HEPES buffer (pH 7.4 and at  
331 60 °C). b. Silver stained SDS-PAGE gel of Mb hydrolysis in the presence of MIP-201 in water  
332 (pH at 7.4 and at 60 °C). c. Nitrogen adsorption isotherms of MIP-201 samples before (◆) and  
333 after the application in hydrolysis of Mb in HEPES buffer (◇) and water (◇).

334 artificial proteases. The reactions were carried out by mixing Mb with MIP-201  
335 in HEPES buffer at 60 °C and analyzing reaction aliquots by SDS-PAGE at  
336 different time increments. The selective hydrolysis of Mb was evidenced by the  
337 appearance of new bands with lower molecular weights (Fig. 4a), and similar  
338 SDS-PAGE pattern was observed when pure water was used as medium (Fig.  
339 4b). In the presence of MIP-201 the hydrolysis of Mb could be already observed  
340 after one hour of incubation, and the intensity of bands with lower molecular  
341 weight (MW) progressively increased with time. The MWs of the protein  
342 fragments formed by hydrolysis of Mb could be estimated using MW ladder in

343 SDS-PAGE experiments. The bands of approximately 14.7, 13.6, 11.9, 10.1 and  
344 6.9 kDa, suggest that Mb was hydrolyzed at Asp20-Ile21, Asp44-Lys45, Asp60-  
345 Leu61 and Asp126-Asp127 peptide bonds, in accordance with the previously  
346 reported affinity of Zr(IV) based artificial proteases to preferentially cleave  
347 proteins next to Asp residues<sup>35</sup>. The hydrolysis of the same peptide bonds in  
348 Mb was also observed in the presence of Zr-POMs, however, those reactions  
349 were much slower, with the observable hydrolysis occurring only after 48 hours  
350 at pH=5.0<sup>35</sup>. The control experiments showed that hydrolysis of Mb was not  
351 observed in the absence of MIP-201 after a four-day incubation at 60 °C,  
352 confirming the catalytic role of MIP-201 in protein hydrolysis. The stability of  
353 MIP-201 after the reaction with Mb was evaluated by a combination of several  
354 techniques performed on samples collected from large-scale reactions.  
355 Nitrogen porosimetry (Fig. 4c), PXRD (Supplementary Fig. 14) and FTIR  
356 (Supplementary Fig. 15) measurements confirmed that the structure of MIP-  
357 201 remained intact after hydrolytic experiments with Mb, further validating its  
358 potential as nanozyme for selective protein hydrolysis.

## 359 **Conclusions**

360 We demonstrate that the microporous MIP-201 reported in this work, which  
361 represents the first Zr-MOF with the soc type topological network, addresses  
362 several challenges related to the development of highly efficient and robust  
363 heterogeneous catalyst for peptide bond hydrolysis. An increase of more than  
364 three orders of magnitude was observed in the rate of the peptide bond

365 hydrolysis in a model dipeptide, highlighting the importance of the 6-  
366 connectivity of  $Zr_6$  oxo-cluster sites in the MIP-201 framework for catalytic  
367 efficiency. Compared to few other MOFs, the most striking advantage of MIP-  
368 201 in catalyzing peptide bond hydrolysis is the possibility to use catalyst under  
369 wide range of reaction conditions, without compromising its stability. MIP-201  
370 was shown to selectively hydrolyze myoglobin which has 153 amino acids in its  
371 sequence, selectively cleaving the protein at only four peptide bonds. The  
372 excellent chemical and architectural stability of MIP-201 confirmed in the  
373 experiments with the protein, in addition to its high catalytic activity and  
374 recycling ability, further highlights its potential as an artificial protease.  
375 Furthermore, the green, scalable and cost-effective synthesis of MIP-201 with  
376 a good product yield makes it a promising and practical alternative for selective  
377 hydrolysis of proteins in proteomics and biotechnology applications.

## 378 **Methods**

379 **Synthesis of MIP-201.**  $Zr(SO_4)_2 \cdot 4H_2O$  (10.8 g) and  $H_4mdip$  (5.1 g) were transferred to  
380 a round bottom flask (1 L), followed by the addition of water (300 mL) and acetic acid  
381 (100 mL) under stirring at room temperature. The reaction was refluxed at 120 °C for  
382 12 hours and cooled to R.T. The resulted solid product was collected by filtration,  
383 washed with ethanol and air dry. Crude product with a light gold color (12.5 g, 90%  
384 yield based on  $H_4mdip$ ) was obtained.

385 **Peptide bond hydrolysis studies.** The hydrolysis reactions were studied at pD 7.4

386 and 60 °C by applying a general procedure. D<sub>2</sub>O (950 μL) was added to a solid sample  
387 of MIP-201 (2.8 mg, 2.0 μmol) in a glass vial followed by stirring for 30 minutes at room  
388 temperature. Peptide (50 μL of 40 mM stock solution, 2.0 μmol) was added to the  
389 suspension and the pH of reaction mixture was adjusted to pD 7.4 by using NaOD.  
390 The samples were incubated at 60 °C. After different time increments the reaction  
391 mixture was centrifuged at 15000 rpm for 20 min to remove the MOF. The <sup>1</sup>H NMR  
392 spectra of the resulting solutions were recorded using TMS<sup>+</sup>-d<sub>4</sub> as internal reference.  
393 The rate constants were obtained by fitting peptide concentrations at different time  
394 increments to a first-order decay function.

395 **Protein hydrolysis studies.** Mb (0.02 mM) was mixed with 2.8 mg of MIP-201 in  
396 HEPES buffer at pH 7.4 or in pure water at pH 7.4. Samples were stirred at 60 °C and  
397 aliquots for SDS-PAGE analysis were taken at different time increments. Stacking gel  
398 was 4% (w/v) polyacrylamide in 0.5 M Tris-HCl buffer at pH 6.8 and resolving gel  
399 consisted of 18% (w/v) polyacrylamide in 1.5 M Tris-HCl buffer at pH 8.8. Sample buffer  
400 (5 μL) was added to 15 μL of the reaction mixture and after heating at 100 °C for 5 min,  
401 10 μL of the resulting solution was loaded on the gel. Molecular mass standard ladder  
402 used in SDS-PAGE was Page Ruler unstained low range protein. An OmniPAGE  
403 electrophoretic cell was combined with an EV243 power supply and the experiments  
404 were performed at 200 V for 1.5 h.

405 **Catalyst recycling experiments.** Recyclability of MIP-201 was tested by repeating  
406 Gly-Gly hydrolysis five times starting from one batch of catalyst in a glass vial. After  
407 each run, the reaction mixture was centrifuged and the solution was used to analyze

408 the amount of unreacted Gly-Gly and the hydrolyzed products (Gly and cyclic Gly-Gly)  
409 by <sup>1</sup>H NMR. Water was added to the solid MOF and stirred for one hour before  
410 removing it. This process was repeated for four times. The MOF material was  
411 subsequently stirred in an organic solvent (chloroform, ethanol, methanol...) for one  
412 day to exchange water. The procedure was repeated twice and the recycled MIP-201  
413 was air dried and activated at 120 °C for four hours before being used for the next  
414 catalytic run.

## 415 **Data availability**

416 All data involved in this work are included in this article and the corresponding  
417 supplementary information. They are available from the corresponding authors upon  
418 reasonable request. The crystal structure data have been deposited at CCDC under  
419 the deposition numbers CCDC: 2076200 and 2076201. These data can be obtained  
420 free of charge from the CCDC database via [www.ccdc.cam.ac.uk](http://www.ccdc.cam.ac.uk).
