Abstract

Background. Hypocomplementemic urticarial vasculitis (HUV) is a rare systemic vasculitis. We aimed to describe the kidney involvement of HUV in a multicenter national cohort with an extended follow-up.

Methods. All patients with HUV (international Schwartz criteria) with a biopsy-proven kidney involvement, identified through a survey of the French Vasculitis Study Group, were included. A systematic literature review on kidney involvement of HUV was performed.

Results. Twelve patients were included, among whom 8 had positive anti-C1q antibodies. All presented with proteinuria, from mild to nephrotic, and 8 displayed acute kidney injury (AKI), requiring temporary haemodialysis in 2. Kidney biopsy showed membrano-proliferative glomerulonephritis (GN) in 8 patients, pauci-immune crescentic GN or necrotizing vasculitis in 3 patients (with a mild to severe interstitial inflammation), and an isolated interstitial nephritis in 1 patient. C1q deposits were observed in the glomeruli (n=6), tubules (n=4) or renal arterioles (n=3) of 8 patients. All patients received corticosteroids, and 9 were also treated with immunosuppressants or apheresis. After a mean follow-up of 8.9 years, 6 patients had a preserved renal function, but 2 patients had developed stage 3-4 chronic kidney disease (CKD) and 4 patients had reached end-stage kidney disease (ESKD), among whom 1 had received a kidney transplant.

Conclusion. Renal involvement of HUV can be responsible for severe AKI, CKD and ESKD. It is not always associated with circulating anti-C1q antibodies. Kidney biopsy shows mostly membrano-proliferative GN or crescentic GN, with frequent C1q deposits in the glomeruli, tubules or arterioles.

Key Messages

- Kidney involvement in HUV can be life-threatening and lead to end-stage kidney disease.
- Glomerular, vascular and tubulo-interstitial compartments can be injured, with frequent C1q deposits.
- Systematic screening for kidney involvement during flares of HUV could accelerate diagnosis and treatment and reduce kidney damage.

Background

Hypocomplementemic urticarial vasculitis (HUV) is a rare systemic vasculitis, also called “McDuffie syndrome” or “anti-C1q vasculitis”. It was classified among immune complex small vessel vasculitides in the revised international Chapel Hill consensus conference in 2012 (1). It was first described by McDuffie et al in 1973 and then well defined in 1982 by Schwartz et al (2, 3). They proposed diagnostic criteria composed of 2 major criteria (recurrent urticarial lesions for at least 6 months and hypocomplementemia) associated with 2 minor criteria among the following: leukocytoclastic vasculitis (on cutaneous biopsy), arthralgia or arthritis, glomerulonephritis, ocular inflammation (uveitis or episcleritis), recurrent abdominal pain or anti-C1q antibody positivity. The frequency of kidney involvement associated with HUV ranges from 14–50% across different cohorts, and is poorly defined (4–6). In the French national cohort published in 2015 by Jachiet et al (5), a kidney involvement of HUV was observed in 10 (18%) patients, but detailed pathological lesions were not available. In addition, little is known on the long-term prognosis of kidney involvement in HUV, and no specific therapeutic strategy is defined in the literature. We describe here the clinical presentation, the pathological lesions and the therapeutic management of a multicentre cohort of 12 patients with biopsy-proven kidney involvement associated with HUV, identified through the French Vasculitis Study Group (FVSG) network.

Methods

This is a multicentre retrospective study, conducted in accordance with the principles of the Declaration of Helsinki. All cases of patients with HUV, as defined by Schwartz criteria, and a biopsy-proven kidney involvement, identified through a survey sent to physicians from the French Study Group on Vasculitis network, were reviewed and included. Some of these patients were included in the national cohort by Jachiet et al.

The following data was collected for each patient: demographic characteristics, systemic symptoms, skin lesions, adenopathy, rheumatic, ocular, eyes nose throat, lung, gastrointestinal, neurologic, cardiac involvement, and detailed renal parameters. AKI was defined according to the RIFLE criteria as R (risk), I (injury) and F (failure) (7). Serum levels of C-reactive protein, complement fractions C3 and C4, anti-C1q antibodies, antinuclear antibodies (ANA), antiphospholipid antibodies, rheumatoid factor, cryoglobulinemia, anti-neutrophil cytoplasmic antibodies (ANCA) and protein electrophoresis were collected. All patients were tested for immunization against hepatitis B, C, HIV and syphilis. Results of skin biopsies were collected when available. All patients had at least one kidney biopsy, analysed by light microscopy and immunofluorescence. Electronic microscopy description was reported when available. The therapeutic strategies, global outcome and renal outcome were collected. Chronic kidney disease (CKD) was defined as a permanently altered kidney function with an estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73m² using the MDRD formula (8).

We then performed a systematic literature review on cases of HUV with renal involvement, using the following MESH terms: Hypocomplementemic urticarial vasculitis, Mac Duffie, kidney/renal involvement, acute kidney injury, chronic kidney disease, glomerulonephritis and kidney/renal biopsy.

For statistical analysis, continuous variables were compared using the Wilcoxon-Mann-Whitney test on mean or median values; categorical variables were compared using the Fisher’s exact test.

Results

Patients’ characteristics

Twelve patients with a biopsy-proven kidney involvement of HUV were identified, of whom 6 were previously included in the cohort of Jachiet et al. Their clinical and biological characteristics are detailed in **Table 1**. Two patients had a paediatric onset of HUV. Chronic urticarial lesions were present in all patients. Arthralgia were reported in 8 patients, with clinical arthritis in 3, and lymphadenopathies in 5 patients. Five patients displayed ocular involvement of HUV: anterior uveitis in 3 patients, conjunctivitis in 2, retinal involvement in two. Pulmonary symptoms (recurrent bronchitis) were described by 3 patients, among whom 1 had chronic respiratory failure. One patient displayed a pericarditis. Anti-C1q antibodies were positive in 8 patients. ANA were detected in 7 patients, among whom one had anti-SSA and anti-double stranded DNA antibodies (patient #12), and another had anti-SSA antibodies and positive cryoglobulinemia (patient #7). ANCA antibodies were detected in 6 patients, among whom 3 had anti-myeloperoxidase (MPO) antibodies, 1 anti-proteinase 3 (PR3) antibodies, and 2 no antigenic specificity.

Renal involvement of HUV

All patients presented with proteinuria, from mild to nephrotic. Eight patients presented with acute kidney injury (AKI), requiring temporary hemodialysis in 2 patients. One patient had stage R, 5 stage I and 3 stage F AKI. Pathological examination of kidney is detailed in **Table 2** for the 12 patients, among whom 2 had a repeat biopsy. Kidney lesions were various, with different patterns of glomerular, vascular, and tubulo-interstitial involvements (**Figure 1**). A membrano-proliferative GN was documented in 8 patients, with crescents in 7, and with a full-house immunofluorescence pattern in 1 patient. Four patients had active vascular lesions: 2 had a necrotizing vasculitis (patients #2 and #11), and 2 had immune deposits of IgG, IgM, C3 and C1q in vascular walls (patient #2 and #9). One patient (#12) had an isolated interstitial nephritis without glomerular or vascular changes. The second biopsies of patients #2 and #7 showed consistent glomerular and vascular patterns, with different levels of inflammatory and fibrotic lesions. The second biopsy of patient #9 showed severe chronic lesions and glomerulosclerosis. Electron microscopy analysis was performed in 2 patients. It showed, in patient #4, abundant and diffuse electron-dense segmental subepithelial and subendothelial granular deposits in capillary walls; in the second biopsy of patient #7, few glomerular electron-dense granular deposits.

Treatment and outcome

Corticosteroids were prescribed in all patients, for all renal flares of HUV, as shown in **Figure 2A**. Corticosteroids were tapered and continued for several years in some patients. An additional immunosuppressive therapy was prescribed in 9 patients. Rituximab was used in 5/12 patients (1 as a first line therapy, 3 after corticosteroids, 1 after cyclophosphamide). It allowed a remission in 4 patients (patient #9, with severe AKI initially requiring dialysis, was not in remission at last follow-up), and was reinfused successfully in 2 patients who relapsed. Patients were followed-up for an average of 8.9 years. The detailed evolution of patients is described in **Figure 3** and **Supplementary Figure 1**. The total number of renal flares per patient ranged from 1 to 8. An infectious trigger for renal relapses was documented in 2 patients (one with pneumococcal pneumonia, and one with several relapses occurring after viral or bacterial infections). Plasma exchanges were used in 2 patients from this cohort: patient #2, for a relapse of HUV with severe AKI, which required also successively mycophenolate mofetil, cyclophosphamide and rituximab; and patient #9, for persistent severe AKI with massive proteinuria despite corticosteroids and rituximab. Patient #2 reached ESKD 2 years later, after an unplanned pregnancy, and received a kidney transplant without further relapse of HUV. Her second pregnancy was carried-out normally while she was transplanted, without HUV relapse.

At last follow-up, all patients were alive. Patient #2 had received a kidney transplant, patients #3 and #7 were on chronic dialysis, patient #9 had stage 5 CKD, patients #2 and #10 had stage 3A CKD. The other 6 patients had a preserved eGFR (≥ 60 mL/min/1.73m²) without proteinuria. A severe complication of immunosuppressive therapy had occurred in 2 patients (one bacterial pneumonia and one cryptococcal meningitis).

Kidney involvement of HUV in the literature

Case reports of kidney involvement of HUV from the literature were collected and compared to patients from the present cohort (**Table 3**) (9–31). The clinical presentation of the 26 patients with kidney involvement of HUV from the literature was consistent with the present work but high blood pressure was more frequent at diagnostic in our cohort ($p=0.005$). The broad range of kidney lesions observed in the present cohort was also observed in the literature. Cryoglobulinemia and ANCA antibodies were more frequent in our cohort (respectively $p=0.002$ and 0.02) and the follow-up was longer ($p=0.002$). Out of these 26 patients, 5 died, 4 reached ESKD and 2 developed stage 3 CKD.

Treatments administered to the patients from the literature are detailed in **Figure 2B**. Two patients with kidney involvement received rituximab as a third line therapy: the first patient experienced a full recovery of kidney function after 12 months of dialysis dependence (31), the second was a child without available data on outcome (24). Plasma exchanges were used in 2 patients from this cohort but were not sufficient and required additional treatment with rituximab or cyclophosphamide. Only 2 patients from the literature were treated with plasma exchanges for AKI (1 reached ESKD, the other reached remission) (13,22).

Considering both the present cohort and patients from the literature (total $n=38$), the presence of anti-C1q antibodies was not associated with outcomes: 41% of patients with positive anti-C1q had an unfavourable outcome (ESKD or death) versus 33% of patients without antiC1q ($p=0.74$).

Discussion

This is the first study describing specifically biopsy-proven kidney involvement of HUV, with detailed pathological data and long term follow-up. We show that HUV can be associated with different glomerular lesions (mainly membrano-proliferative GN, but also crescentic GN, with or without immune glomerular deposits), lesions of renal arterioles (both acute and chronic, sometimes with C1q and immune complex deposits), and tubulo-interstitial inflammation (sometimes with tubular C1q and immune complex deposits). Notably, at the time of kidney biopsy, the interstitial fibrosis was often absent or mild, suggesting a rapid and recent occurrence of renal lesions. This kidney involvement can be life-threatening, with AKI requiring emergency dialysis, and can lead

to ESKD. Yet, even with a severe initial presentation, a complete renal recovery can be obtained with corticosteroids, and possibly immunosuppressive therapy, in a majority of patients.

HUV is an immune-complex mediated systemic vasculitis affecting small vessels (1). Immune complex deposits in vessel walls are usually documented on skin biopsies of urticarial lesions, and we show here that these deposits, comprising C1q, can also be encountered in renal arterioles.

Yet, immune deposits are not systematic in the kidney of patients with HUV, especially in glomeruli, where pauci-immune forms of crescentic GN can be encountered. An overlap between HUV and ANCA-associated vasculitis (AAV) could be discussed in these patients. Here, among the 6 patients with positive ANCA antibodies, only 4 had specific ANCA, among whom 3 displayed membrano-proliferative GN (classically not encountered in AAV) and only 1 displayed pauci-immune CGN. This last patient, indeed, both responded to HUV classification criteria (chronic urticaria, complement consumption, arthralgia, glomerulonephritis, and anti-C1q antibodies) and displayed features of AAV (arthralgia, glomerulonephritis and anti-MPO antibodies).

Similarly, the possible overlap between HUV and systemic lupus erythematosus can be discussed in patients with positive ANA. Among the 7 patients with positive ANA, only 1 had anti-dsDNA, and displayed isolated interstitial nephritis. Only 1 patient with positive ANA displayed a membrano-proliferative GN with full-house immune deposits. Apart from this kidney involvement, this patient had no specific feature of lupus but displayed: biopsy-proven cutaneous leukocytoclastic vasculitis, angioedema, and recurrent bronchitis with chronic respiratory failure.

HUV is a rare disease, but its exact incidence is unknown (6). Kidney involvement of HUV is even more rare: in the largest retrospective cohort of HUV, comprising 57 cases gathered in France over 20 years, 10 (18%) patients displayed kidney involvement of HUV (5). In an American cohort comprising 18 patients with HUV, 9 (50%) patients displayed kidney involvement (4). More recently, a Swedish cohort of 16 patients reported 5 patients with kidney involvement, among whom 2 reached ESKD (6). Membrano-proliferative GN, membranous GN, minimal change disease, focal glomerulopathy and anti-glomerular basement membrane nephritis have been described in the literature (32). We confirm in this work the heterogeneity of clinical presentation and kidney pathological lesions in patients with HUV.

AntiC1q antibodies are IgG antibodies directed against the collagen-like region of C1q. They are encountered in HUV and in other diseases associated with immune complex deposition, such as mixed connective tissue disorder, systemic lupus erythematosus and post-infectious vasculitis (5). The presence of anti-C1q antibodies has been associated with kidney involvement in lupus, and more specifically with crescentic lesions (33). The presence of anti-C1q antibodies was only a minor criterion in Schwartz et al (2), but was considered more discriminant in the revised international Chapel Hill consensus conference of 2012 (1). However, the specificity and sensitivity of anti-C1q antibodies are unknown. Their presence is neither sufficient nor mandatory to diagnose HUV: 67% of patients from the present cohort, and 38% of patients from the literature had positive anti-C1q antibodies. In the French retrospective cohort by Jachiet et al, 55% of HUV patients had positive anti-C1q antibodies and 90% had a low C1q, and 88% from the American cohort by Wisnieski et al had positive anti-C1q antibodies. The prognostic value of anti-C1q antibodies in HUV is controversial: it was associated with renal involvement in the French cohort by Jachiet et al, but showed no prognostic value for the global outcome (ESKD or death) in the present cohort and in the literature review of patients with kidney involvement.

The treatment of HUV and of its kidney involvement is far from established. While corticosteroids were used in all patients from the present cohort, Rituximab was used mostly as a 2nd or 3rd line therapy, but could be proposed as a corticoid-sparing agent in relapsing forms of HUV.

We underline the value of repeat kidney biopsy in these patients, which can allow the differentiation of active versus chronic renal lesions and guide the need for immunosuppressive regimen.

Conclusion

Patients with HUV can display heterogeneous kidney lesions with glomerular, vascular and tubulo-interstitial involvement, with or without immune complex deposits. Kidney involvement of HUV can be severe and relapsing, and lead to ESKD. Corticosteroids, and Rituximab in severe forms, could be the preferential therapeutic options. Screening for proteinuria, and monitoring of blood pressure and serum creatinine could be proposed in all patients with HUV followed-up in Rheumatology or Dermatology, at the time of the diagnosis and during subsequent flares, to diagnose and treat kidney lesions early to avoid chronic kidney damage.

Abbreviations

AKI: acute kidney injury

ANA: anti-nuclear antibodies

ANCA: anti-neutrophil cytoplasmic antibodies

CKD: chronic kidney disease

ESKD: end-stage kidney disease

GN: glomerulonephritis

HUV: hypocomplementemic urticarial vasculitis

MPO: myeloperoxidase

Declarations

Ethics approval and consent to participate: this study was conducted in accordance with the principles of the Declaration of Helsinki. All methods were carried out in accordance with relevant guidelines and regulations. The experimental design was approved by the relevant licensing committee in France, the CNIL (Commission Nationale Informatique et Liberté), with the approval number 2019_104.

Consent for publication: not applicable, only the authorization of the CNIL being required according to the French legislation for the publication of patient data collected retrospectively and anonymously.

Disclosure statement: the authors have no conflict of interest to declare.

Availability of data and material: the datasets used and/or analysed during the current study are available from the corresponding author on reasonable request.

Funding: no funding was received for this work.

Authors' contributions: AC acquired the data and wrote the manuscript with NJC. MJ, AS, CB, AB, MSD, DiB, AB, OM contributed to collect data on patients' cases. DaB, NB contributed on laboratory data extraction. BT, XP contributed on patient recruitment through the FVSG network. LD was responsible for renal pathological interpretation. All authors read the final manuscript and approved it.

Acknowledgements: we thank Alain Vazi and Laurent Samson for their help with the serum biobank.

PRESS: Posterior reversible encephalopathy syndrome, CRP: C-reactive protein, ESR: elevated sedimentation rate, ANCA: anti-neutrophil cytoplasmic antibodies, GN: glomerulonephritis, eGFR: estimated glomerular filtration rate.

Figures

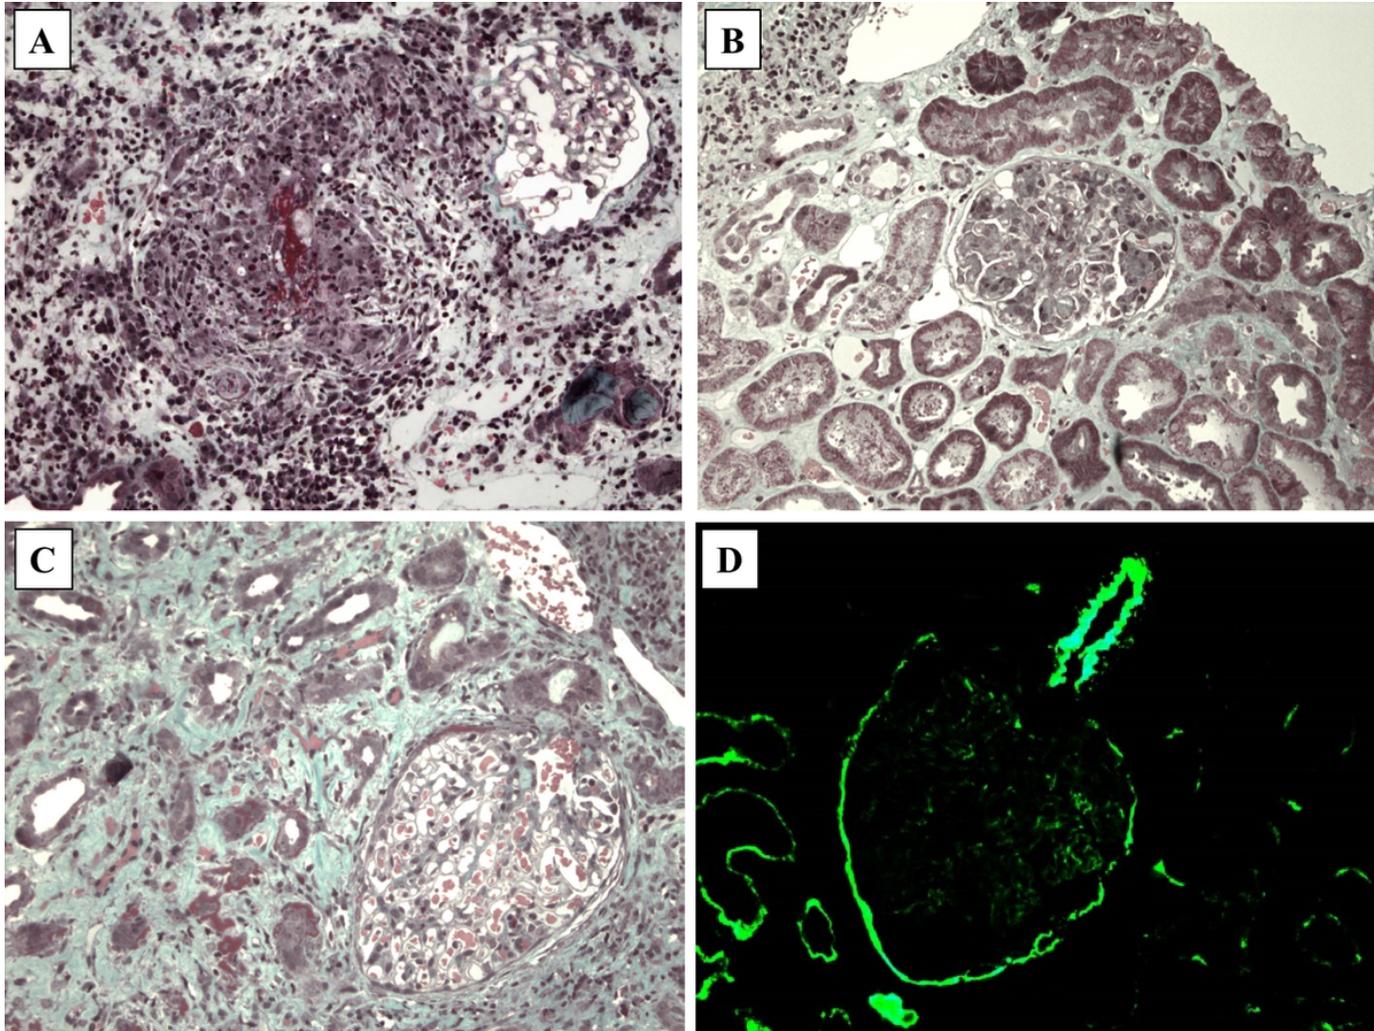

Figure 1
 Representative kidney pathological lesions observed in patients with Hypocomplementemic Urticarial Vasculitis from the present cohort. A. Vasculitis with fibrinoid necrosis involving a pre-glomerular arteriole. Masson's trichrome, x 200. B. Global endocapillary proliferation with an interstitium containing a slight peri-venular inflammatory infiltrate. Masson's trichrome, x 200. C. Interstitial nephritis with mononuclear cells, oedema, and suffering tubules. Masson's trichrome, x 200. D. Abundant deposits of C1q within arteriole wall, capsule, and tubular basement membrane. Immunofluorescence, x 200

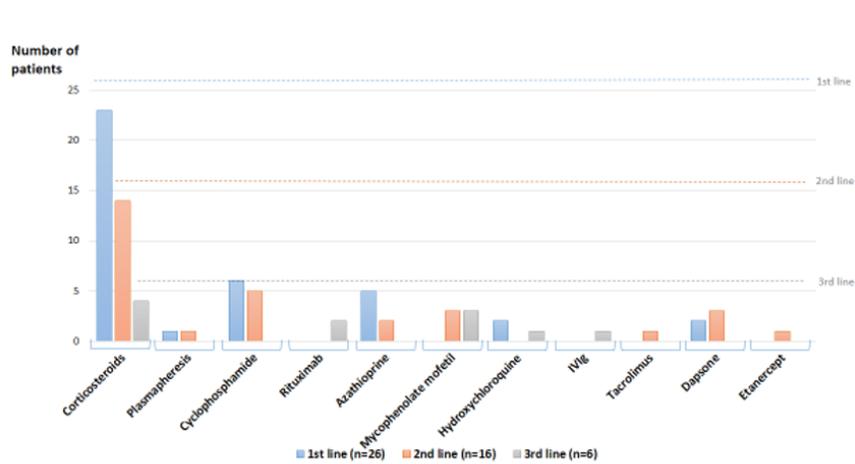

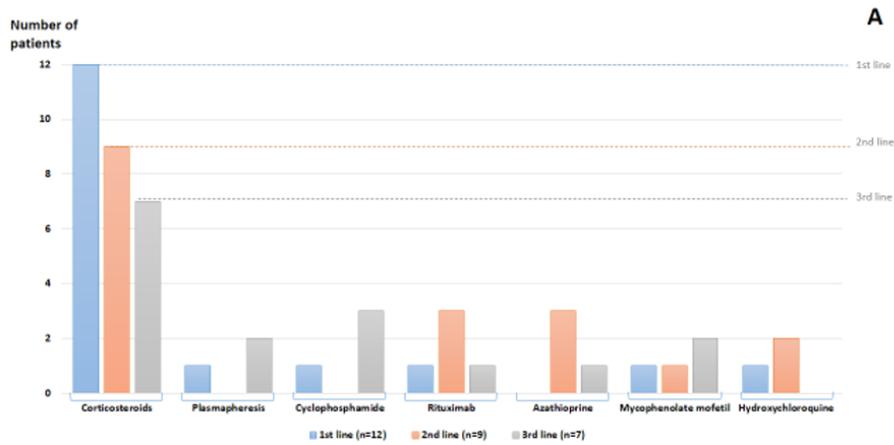

Figure 2

Treatment of the kidney involvement of HUV (first, second and third line therapies) A. In the 12 patients from the present cohort. B. In the 26 patients from the literature.

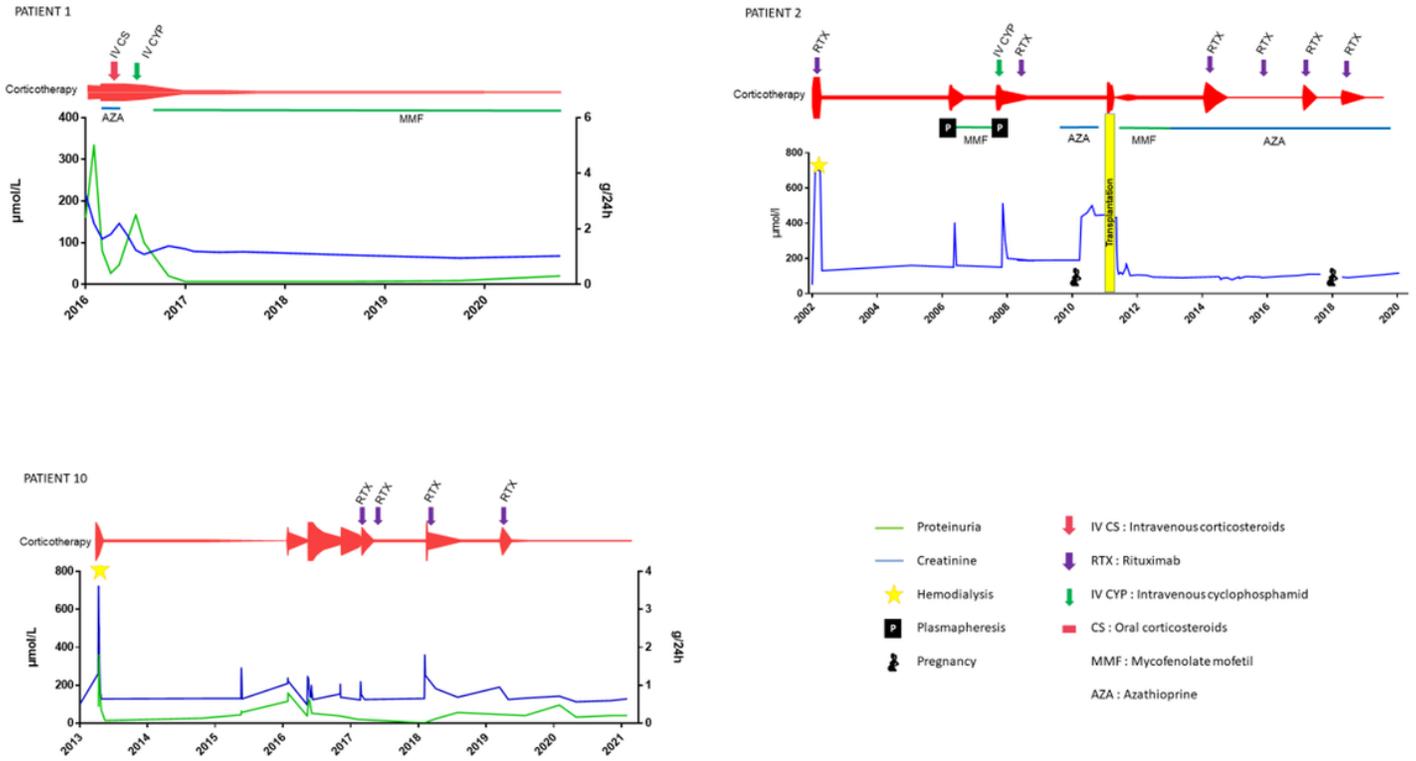

Figure 3

Treatment and renal outcome in 3 patients representative of the present cohort (patients #1, #2 and #10).
