Abstract

Background

Coronary steal phenomenon and myocardial ischemia is a complication following decompression of a hypertensive right ventricle in patients with left coronary-cameral fistulae.

Case presentation

We present a 12-year-old girl with a complex heart defect successfully operated on using a hybrid surgical-interventional approach to decompress the ventricle, embolize the fistula and reconstruct the atretic left coronary ostium.

Conclusions

A novel hybrid strategy is the best solution for coronary-cameral fistulas reliant on high ventricular pressure at high risk for coronary steal phenomenon.

1. Introduction

Atresia of the left coronary artery ostium (ALCAO) is one of the rarest congenital coronary anomalies, in which a solitary right coronary artery supplies the entire myocardium. The myocardium may receive additional perfusion via fistulas from hypertensive ventricles [1,2]. Unilateral coronary ostial atresia usually follows complex heart defects as in the presented case with pulmonary atresia causing critical stenosis with an intact ventricle septum and hypertensive right ventricle chamber. Patients with ALCAO and insufficient coronary perfusion may develop variable symptoms including chest pain, fatigue, dyspnea, arrhythmias, syncope, cardiac compromise and sudden cardiac death [3]. In most children with ALCAO the perioperative mortality is high, therefore heart transplant is the viable option (4,5). We present a novel surgical-interventional hybrid alternative for successful restoration of anatomical and physiological coronary circulation complicated by myocardial ischemia due to coronary steal phenomenon.

5. Patient Information

A 12-year-old girl with severe pulmonary valvar stenosis (PVS), atretic left main coronary artery ostium (ALCAO) and a wide fistula between the hypertensive right ventricle (RV) and the left coronary artery received surgical follow-up consultation.

6. Clinical Findings

The child had NYHA class II-III, episodic abdominal pain and exertional dyspnea. Physical examination showed good general condition, regular heart rate of 70 beats/min, loud systolic murmur of 4-5/6 on

Levine scale with a thrill over the chest and jugular notch. Blood pressure was 100/60mmHg, respiratory rate 14 breaths/min and SaO₂ 96% on room air.

7. Timeline

The known heart defect was diagnosed at birth. Neonatal balloon pulmonary valvuloplasty permitted corrective surgery to be postponed. Heart transplant remained a viable option due to high clinical risk status and operation complexity. The patient attended for echocardiography for 12-year follow-up prior to admission to the cardiac surgery department.

8. Diagnostic Assessment

Normal sinus rhythm with right axis deviation and severe right ventricular hypertrophy were found on ECG. Roentgenogram showed cardiomegaly, pulmonary trunk dilatation and right atrium enlargement. TTE visualized 2nd degree tricuspid valve regurgitation with pressure gradient of 138mmHg, and PVS pressure gradient of 148mmHg. Hemodynamic studies recorded increased central venous (12mmHg), LV end-diastolic (15mmHg) and suprasystemic RV pressures (127/15mmHg).

Angiographic studies illustrated wide RCA (5mm) and atretic ostium of the LMCA (Figure 1, Supplemental Video1). Right ventriculography outlined severe pulmonary valvar stenosis with dome-shaped valve leaflets and post-stenotic pulmonary trunk dilatation. Furthermore, selective fistula angiography and 3D rendered Computed Tomography depicted ALCAO and a wide coronary fistula emerging from the hypertrophic RV (Figures 2, 3; Supplemental Video 2, 3). The fistula orifice sat superficially in the anterior interventricular groove. Multiple proximal and distal converging collateral anastomoses were present between the LMCA and RCA. The LMCA divided into the left anterior descending artery (LAD) and the circumflex artery (CX).

9. Therapeutic Intervention

The patient was qualified for LMCA ostium reconstruction and simultaneous interventional fistula embolization. Sternotomy with cross-clamped aorta and cannulated caval veins under 24°C hypothermia on cardiopulmonary bypass supported the patient. The RCA cardioplegic solution infusion sustained electromechanical quiescence to asystole. Epicardial fat meant the fistula was not visible. The ascending aorta, bulb and proximal LMCA segment were precisely dissected. The ostium was atretic due to a fibrous diaphragm which was excised, and the artery reconstructed with a Biointegral patch. Next, a RVOT infundibulectomy was undertaken with pulmonary commissurotomy and partial resection of the dysplastic leaflets. The now reconstructed and patent LMCA ostium provided a conduit for a multipurpose 5-F catheter over a 0.025-inch hydrophilic steerable guidewire. The fistula branches were implanted with two 6mm diameter Amplatzer Vascular Plugs II (St. Jude Medical, St Paul, MN). Intraoperative epicardial ECHO confirmed antegrade LMCA flow, normal myocardial contractility, and minor fistula leak. The cross-clamp was released and normal sinus rhythm without ischemic ECG changes emerged upon myocardial reperfusion. Post-operative hemodynamic catheterization revealed

high RV systolic and diastolic pressures (60/25mmHg), LVEDP (90/26mmHg), central venous pressure (25mmHg), pulmonary venous hypertension (mean 30mmHg) with increased pulmonary flow. Residual fistula leaks (Figure 4, Supplemental Video 4) required interventional endovascular embolization using multiple occluders which were redelivered via LMCA without sequelae (Figure 5, Supplemental Video 5).

10. Follow-up and Outcomes

At 2-year follow-up the girl was asymptomatic on pharmacotherapy (metoprolol and aspirin) with good exercise tolerance (NYHA II). Resting ECG showed normal sinus rhythm without symptoms of ischemia while 2DE revealed good EF (50%) and sealed fistula.

2. Discussion

Ischemic ALCAO with cardiomyopathy is an indication for urgent surgery using a left internal mammary artery bypass graft, although in complex heart defects and small children heart transplant is considered a viable option. Our patient's resting ECG was not suggestive of ischemia as suprasystemic RV pressure and wide fistula patency secured left coronary flow despite ALCAO. Yet, upon reconstructing the LMCA ostium and decompressing the RV, coronary steal phenomenon and heart failure ensued. In small children, coronary ostium reconstruction with a patch offers an alternative solution [4]. In those with a coronary fistula, traditional surgical ligation is preferential to avoid myocardial ischemia [5]. However, the fistula orifice is difficult to visualize and precisely ligate. Patched coronary ostium reconstruction and simultaneous hybrid fistula embolization are viable procedures in anomalies technically difficult to approach. Our concerns about RV decompression and coronary steal phenomenon proved to be well founded as further embolization were needed for residual fistula leakage.

Critical considerations and limitations of the presented case include shortage of published literature and guidelines for children with coronary anomalies. Rigid surgical-only solutions proposed in the literature lack flexibility to adapt to individual cases which appears to be crucial. For instance, a pragmatic approach depends on body weight, coexisting heart defects, hemodynamic flow, and the surgeon's experience. In the presented case, the authors demonstrate the viability of a hybrid approach to complex coronary anomalies with high perioperative mortality to restore functional anatomy and physiology.

The learning objective recalls the risk of the coronary steal phenomenon appearing after hypertensive RV decompression – a key source of coronary perfusion in patients with cameral fistulas. Complex congenital coronary anomalies with technical difficulty ought to strongly consider a hybrid treatment with staged planning and close hemodynamic monitoring.

12. Patient Perspective

The patient shared an optimistic outlook toward attending high school despite restricted sports participation and pharmacotherapy.

The family were grateful to the medical staff for the complex yet successful treatment which avoided heart transplant.

13. Informed consent

Informed consent to publish was obtained from the patient's mother.

Abbreviations

ALCAO – atresia of the left coronary artery ostium

EF – ejection fraction

LMCA – left main coronary artery

LV – left ventricle

LVEDP - left ventricle end-diastolic pressure

NYHA - New York Heart Association – functional classification of heart failure

RCA – right coronary artery

PVS – pulmonary valvar stenosis

RV – right ventricle

RVEDP – right ventricle end-diastolic pressure

TTE – transthoracic echocardiogram

Declarations

Ethics approval and consent to participate

Awaiting bioethics committee approval

Consent for publication

Informed consent to publish was obtained from the patient's mother.

Availability of data and materials

The data are available for public access.

Competing interests

The authors declare that they have no competing interests.

Funding

The authors declare that this work is supported by the grant of Medical University of Warsaw.

Authors' contributions: JK, WKJ and KG diagnosed the patient. JP, MAK, MB, and PW performed the surgery. JK, WM, DJG and LTM were major contributors in writing the manuscript. All authors read and approved the final manuscript.

Acknowledgments

We thank the patient's parents for allowing us to present the treatment history. We also thank PhD M. Karolczak, head of the Department of Cardiac and General Pediatric Surgery for substantive guidance and supervision.
