Abstract

Rotenone is a naturally occurring compound and inhibitor of mitochondrial complex I. Its exposure is toxic and directly affects the function of mitochondrial which leads to neurodegeneration. Taxifolin is a flavonoid that exhibits therapeutic potentials in various neurodegenerative diseases via its anti-oxidative, anti-inflammatory and neuromodulatory properties. In this study, we evaluated the therapeutic potential of taxifolin to alleviate metabolic and neurochemical alterations in the hippocampal and cortical region of brain of rotenone-toxified rats *in vivo* and to assess its influence on some enzymes involve in neurotransmission *in silico*. Taxifolin (0.25, 0.5 and 1.0 mg/kg) was orally post-administered to male Wistar rats for 3 days after 10 days subcutaneous administration of rotenone. Activities of mitochondrial complex I, membrane ion pump and lactate dehydrogenase (LDH) were evaluated in the hippocampus and cortex of the brain of rotenone-toxified rats. Markers of neurotransmitter metabolism and oxidative stress were also biochemically estimated and molecular interaction between taxifolin and tyrosine hydroxylase, monoamine oxidase, glutamine synthetase and Na^+K^+ ATPase was determined by *in silico* simulation. Taxifolin attenuated dysfunction of mitochondrial, Na^+K^+ ATPase, LDH and modulate neurotransmitter metabolism. Also, the elicited oxidative stress was mitigated by taxifolin in the hippocampus and cortex of the brain of rotenone-toxified rats. The highest binding affinity was recorded in taxifolin and tyrosine hydroxylase complex. Hydrogen bond and hydrophobic interactions were the two key molecular interaction between the taxifolin and targeted enzymes. Thus, taxifolin significantly exert therapeutic effect against rotenone-induced neurotoxicity in rats via anti-oxidative, as well as mitochondrial and neurotransmitter modulatory activity.

1. Introduction

Rotenone is a naturally occurring compound which can be employed as a broad spectrum organic pesticide. Also, it is a lipophilic compound that can readily cross cellular membrane after environmental exposure and cause a toxic effect to the brain (Yarmohammadi et al. 2020). Therefore, exposure to rotenone may lead to progressive deterioration of brain function that are characteristics of neurodegenerative diseases such as Alzheimer's disease (AD) and Parkinson's disease (PD) (Garabadu and Agrawal 2020). Consequently, rotenone neurotoxicity is reproduced into animal experimental model to mimic pathological features of PD since dopaminergic neuron of substantial nigra, among other neuronal cell types in other regions of the brain, are more susceptible to rotenone toxicity (Zhou et al. 2016). Besides the substantial nigra of striatal region of the brain, other regions that are prone to rotenone neurotoxicity includes the hippocampus and cortex and it may affects the functions of these brain regions (Sai et al. 2009; Zhou et al. 2016).

The primary toxicological effect of rotenone on brain cells (such as dopaminergic neuron and other cell types) is the inhibition of mitochondrial complex I activity which leads to overproduction of reactive oxygen species (ROS) and caused mitochondrial dysfunction (Tamilselvam et al. 2013). Mitochondrial is a very important sub-cellular organelle that plays a crucial role in modulating metabolic activity of brain cells such as ATP synthesis (Liu et al. 2005) and in promoting neuronal function, such as membrane ion

pumps and channel activity and synaptic transmission (Sai et al. 2009). Dysfunction of the mitochondrial may leads to dysfunction of neurochemical (enzymes/protein) that may ultimately leads to death and degeneration of neuronal cells, resulting to functional deficits of the brain.

The development of drugs that are available for the management of neurotoxicity arising as a result of intolerant exposure to rotenone is faced with numerous side effects and are of limited benefit. Therefore, it is essential to establish an effective and alternative drug/therapy that could combat rotenone intoxication with minimal or no side effect. Natural compounds have been reported to have little or fewer side effect and also exhibit impressive pharmacological activities (Jia et al. 2018; Paunkov et al. 2019). Many studies have reported the potential therapeutic effect of natural compounds such as flavonoids, on brain injury through antioxidant and anti-inflammation (Anusha et al. 2017; Ma et al. 2018). The structural features of flavonoids such as C₂ and C₃ double bond, 4- carbonyl group, hydroxylation pattern, particularly the 3-OH and ring B catechol moiety, has been attributed to their pharmacological properties (Wang et al. 2018).

Taxifolin (3,5,7,3,4-pentahydroxy flavanone or dihydroquercetin), a flavanone subclass of flavonoids, which are mostly found in citrus fruit. The double bond between carbon 2 and 3 of the C-ring in the structural of taxifolin is saturated (Fig. 1). It has been reported that taxifolin promote the expression of phase II antioxidant and detoxifying enzymes and present a defensive role to the cell against DNA oxidative damage (Liang et al. 2013). Taxifolin has also been reported to present its anti-inflammatory effect by scavenging myeloperoxidase (MPO)-derived reactive nitrogen species (RNS) and showed inhibitory action against the excess production of reactive oxygen species (ROS) during brain injury (Weidmann 2012; Razak et al. 2018). Though, the bioactivity of flavonoids against neurological disease has been mostly attributed to their classical antioxidant effect, there are evidences that they also act by modulating neurotransmitter and mitigate mitochondrial dysfunction, control of neuronal signaling pathways, as well as interacting with inflammatory mediators and chelating transition metal. Hence, this study is designed to evaluate the neurotherapeutic potential of taxifolin to relieve metabolic and neurochemical alterations in the hippocampal and cortical region of brain of rotenone-toxified rats *in vivo* and its interaction with certain enzymes involve in neurotransmission *in silico*.

2. Material And Methods

2.1 Chemicals and reagents

Rotenone (R8875-1G), (±)-taxifolin (3,5,7,3,4-pentahydroxy flavanone hydrate; T4512-25MG), thiobarbituric acid (TBA; T5500-25G), trichloroacetic acid (TCA), reduced glutathione (GSH; G4251), glutamic acid (49621-250G), adenosine triphosphate (ATP; A26209-1G), 6,7-Dimethyl-5,6,7,8-tetrahydropterine (DMTHP; D0387-100MG), 5',5'-dithiobis-(2-nitrobenzoic acid) (DTNB; D218200-1G), perchloric acid (PCA; 1.09065), benzylamine hydrochloride (BAHC; B5136-25G), xanthine (X7375-10G), dopamine hydrochloride (H8502-5G), reduced nicotinamide-dinucleotide (NADH; N7004-25MG), ethylenediaminetetraacetic acid (EDTA; 03620-250G), 8-anilino-1-naphthalene sulfonic acid (ANSA;

A1028-5G), 2,4-dinitrophenyl hydrazine (DNPH; D199303-25G), acetylcholine iodide (A7000-5G), coenzyme Q10 (C9538-100MG), α -ketoglutarate (75892-25G), epinephrine (E4250-1G), tetramethylbenzidine (TMB; T19607-100G), L-Tyrosine (T3754), Bradford reagent (B6916-500ML), bovine serum albumin (BSA) and ammonium molybdate (A7302-100G) were all obtained from Sigma-Aldrich (St. Louis, MO, USA). All other chemicals and reagents used were of analytical grade.

2.2 Animal grouping and treatment

Male Wistar rats (200 ± 30 g) were housed in the Animal House of the Department of Biochemistry, the Federal University of Technology Akure, Nigeria. They were fed with standard rat chow and water *ad libitum*. Animals were handled and used following the National Institute of Health, NIH, Guide for the Care and Use of Laboratory Animals, 2011. The experiments were approved by the institutional Committee for the Ethical Use of Research Animals of the Federal University of Technology, Akure (Ethical approval No: FUTA/ETH/2020/013). Animals were randomly assigned to the vehicle or treatment group.

The sample size of the animals used for the *in vivo* experiment was calculated as described by Yamane (1967). For the animal grouping, we assumed a total population of 71 rats and we calculated the sample size from the assumed population of the rats as follows;

$$n = \frac{N}{1+N(e^2)}$$

Where; n = sample size, N = the population of study, and e = the accepted sampling error (i.e. ± 0.05). So, the sample size is calculated thus:

$$n = \frac{71}{1+71(0.05^2)}$$

$$n = \frac{71}{1+0.1775}$$

$$n = \frac{71}{1.1775}$$

$n = 60.29 \approx 60$ rats in total for the *in vivo* experiment.

The sixty (60) rats were then divided into five groups with 12 animals per group. Group I: rats received the vehicle (corn oil) only (control); Group II: rats were subcutaneously administered rotenone (Rotenone); Groups III-V: rats were subcutaneously administered rotenone and thereafter post-treated with taxifolin (ROT + TAX (0.25, 0.5, 1.0 mg/kg)). Rotenone (1.5 mg/kg) was subcutaneously administered for 10 days, followed by post-treatment with varying doses of the taxifolin for 3 days through the same route (Akinmoladun et al. 2018; Thiffault et al. 2000). The doses of taxifolin used in this study were based on other study and on the preliminary study in our laboratory (Arutyunyan et al. 2013; Akinmoladun et al. 2018).

After the last day of treatment, the animals were sacrificed by intraperitoneal injection with overdose of chloral hydrate (400 mg/kg) anesthesia and their brain was excised, rinsed in ice cold 1.15% (w/v) potassium chloride solution, blotted with filter paper and weighed. The hippocampus and cortex of the brain were separated and processed for biochemical estimation. The hippocampus and cortex of the brain were then homogenized separately in phosphate buffered saline (pH 7.4, 10% w/v) with a Teflon homogenizer and centrifuged at 10,000 *g* for 25 minutes at 4°C to obtain the supernatants (test sample) which were used for biochemical analyses. The method of Bradford (1976) was followed to determine the concentration of protein in the test sample.

2.3 Biochemical estimation

2.3.1 Estimation of mitochondrial and neurochemical dysfunction markers in the hippocampus and cortex

NADH oxidoreductase (complex I) activity in the test sample was estimated by a previously described method (Birch-Machin et al. 1994). Evaluation of Na⁺/K⁺-ATPase activity was carried out using previously described method (Svoboda and Mosinger 1981). Lactate dehydrogenase (LDH) activity was evaluated by a previously described method (Tienhaara and Meany 1973).

2.3.2 Estimation of neurotransmitter metabolism in the hippocampus and cortex

2.3.2.1 Evaluation of dopamine metabolism

The activity of tyrosine hydroxylase (TH) in the test sample was estimated according to the method of Craine et al. (1972). Monoamine oxidase (MAO) activity was evaluated by a previously described method (Chaudhary and Parvez 2012). Dopamine (DA) concentration in the test sample was determined by the method described by Guo et al. (2009).

2.3.2.2 Evaluation of acetylcholinesterase activity (acetylcholine metabolism)

Acetylcholinesterase (AChE) activity was evaluated using the method of Ellman et al. (1961). AChE activity was expressed in μmol of thiocholine produced $\text{min}^{-1}\text{mg protein}^{-1}$.

2.3.2.3 Evaluation of glutamate metabolism

Glutamine synthetase (GS) activity was evaluated as previously described by Stanimirovic et al. (1999) and the activity of glutamate dehydrogenase (GDH) was evaluated by the method of Abdel-Zaher et al. (2011).

2.3.4 Evaluation of oxidative stress in the hippocampus and cortex

The method of Beutler et al. (1985) was followed to determine the level of reduced glutathione (GSH). Glutathione peroxidase (GPx) activity was estimated according to the method of Haque et al. (2003). The activity of superoxide dismutase (SOD) was evaluated by the method of Kakkar et al. (1984). Catalase (CAT) activity was evaluated according to the method of Clairborne (1985). Ferric reducing antioxidant power (FRAP) was determined using the method of Benzie and Strain (1996). The extent of lipid peroxidation was determined by measuring the formation of thiobarbituric acid reactive substances (TBARS) according to the method described by Varshney and Kale (1990). Protein carbonyl (PC) content was determined using the method of Levine et al. (1990). Evaluation of xanthine oxidase (XO) activity was performed according to the method of Prajda and Weber (1975). Determination of nitrite level was carried out using Griess reaction (Guevara et al. 1998). The determination of total protein concentration was carried out using the method described by Bradford (1976).

2.3.5 Evaluation of myeloperoxidase (MPO) activity in the hippocampus and cortex

Assessment of Myeloperoxidase (MPO) activity was carried out according to the method of Eiserich et al. (1998). MPO activity is defined as the quantity of enzyme degrading one μmol peroxide min^{-1} and was expressed in units per mg protein.

2.4 Molecular docking of taxifolin with target enzymes *in silico*

Three dimensional (3D) structure of the ligand, taxifolin (CID: 439533), was obtained from PubChem NCBI database (<https://www.ncbi.nlm.nih.gov/pubmed/>) in simple file format (SDF), while the 3D X-ray crystal structures of our target receptors namely; TH, MAO, GS and Na^+/K^+ -ATPase were acquired from the Protein Data Bank (PDB) of RCSB server with PDB identities of 2Z5X (Son et al. 2008), 2XSN (Parveen et al. 2016), 2OJW (Krajewski et al. 2008) and 2ZXE (Shinoda et al. 2009), respectively. Taxifolin was loaded onto Open Babel segment of Python Prescription suite and were minimized using Merck Molecular Force Field 94 (MMF94). The target enzymes were then prepared for docking by selecting the General Amber Force Field 2 implemented in Cresset Flare© software, version 4.0 (<https://www.cresset-group.com/flare/>). Auto Dock Vina (Trott and Olson 2010) was employed to execute the docking steps using a flexible docking protocol. Grid box was set for each targets' active site as shown in Table 1. Thereafter, taxifolin was docked into the active domain of all the enzymes after which 10 binding postures for ligand-protein complex was made. The binding energy of taxifolin with corresponding enzyme targets was documented. The ligand-protein complex with the molecular interaction was prepared with PyMOL© Molecular Graphics 2.4 (Shrodinger LLC) and was visualized in 3D and 2D using PyMOL© Molecular Graphics and LigPlot⁺ ver. 1.4.5.

Table 1
The three-dimensional affinity grid parameters for geometric centre of each targeted enzyme and their dimension

Parameters	Axis	TH	MAO	GS	Na ⁺ /K ⁺ -ATPase

2.5 Statistical analysis

Statistical data were analyzed with SPSS 25.0 software (SPSS, Armonk, NY, USA) and graphs were drawn with graphics were drawn with Graphpad Prism 6.01 (GraphPad Software, Inc., USA). Quantitative data are expressed as the mean \pm standard deviation (SD). Kolmogorov-Smirnov tests were performed to test normality. Levene's test was used to assess the homogeneity of variance. Differences among multiple groups were analyzed by one-way ANOVA with the post hoc Tukey test when the assumptions of normality and homogeneity of variance were met or, if heterogeneity of variance was detected, by the Kruskal–Walli non-parametric analysis of variance followed by Tamhané's test for multiple comparisons between the assays (Table 2). The tests for normality and variance heterogeneity and other relevant statistical information are highlighted in the supplementary material. In all tests, $p < 0.05$ was taken as a criterion for statistical significance.

Table 2

Test Statistic outputs by One Way Analysis of Variance with all pairwise multiple comparison procedures done via Tukey Test

3. Result

This study is on *in vivo* biochemical and *in silico* simulation and a blind experimenter is not needed for the experiment. The analysis of the results are not influenced by the experimenter.

3.1 Taxifolin assuaged hippocampal and cortical mitochondrial and neurochemical dysfunction in rotenone-toxified rats

Rotenone is a mitochondrial complex I blocker that has an effect on neuronal excitability and the rate of glucose catabolism. The benefit of taxifolin to alleviate this anomaly in the hippocampus and cortex of rotenone-toxified rats was therefore evaluated in this study.

Figure 2(a-c) showed the effect of taxifolin in reducing mitochondrial and neurochemical dysfunction in hippocampus and cortex of brain of rats occasioned by rotenone intoxication. Rotenone intoxication caused a significant reduction ($p < 0.0001$) of complex 1 activity which indicates mitochondrial damage. Hippocampus and cortex of rats post-treated with taxifolin at all doses showed significant increase ($p < 0.0001$) in complex I activity (Fig. 2a). Figure 2b showed a significant decrease ($p < 0.0001$) in the hippocampal and cortical Na^+/K^+ ATPase activity of rat intoxicated with rotenone compared to control. Rats treated with taxifolin showed increased activity ($p < 0.0001$) of Na^+/K^+ ATPase compared to rotenone-toxified rats. In Fig. 2c, LDH activity of rats intoxicated with rotenone increases compared to the

control rats signifying lactic acid build up. LDH activity significantly decreased ($p < 0.0001$) in rats post-treated with taxifolin signifying reduced acidosis compared to rotenone-toxified rats without treatment.

3.2 Neurotransmitter dysregulation in rotenone-toxified rats was ameliorated by taxifolin

Neurotransmitter dysregulation was carried out to check the involvement of glutaminergic, cholinergic and dopaminergic system in the hippocampus and cortex of rats subjected to rotenone neurotoxicity and the therapeutic effect of taxifolin to correct the dysfunction in neurotransmitters was assessed. Rotenone intoxication caused hippocampal and cortical dysregulation in dopamine (Fig. 3a-c), acetylcholine (Fig. 4) and glutamine metabolism (Fig. 5a-b) in the brain of rats.

There is significant decrease ($p < 0.0001$) in TH activity in rotenone-toxified rats compared to control which indicate reduced formation of L-DOPA (Fig. 3a). Also, MAO activity significantly decreased (Fig. 3b) with a concomitant reduction ($p < 0.05$) in dopamine level (Fig. 3c) in the brain of rotenone-toxified rats compared to control. This anomaly in dopamine metabolism was significantly mitigated ($p < 0.0001$) by taxifolin post-treatment at all doses, except 0.25 mg/kg taxifolin treatment at the cortical region which did not have effect on MAO activity.

Figure 4 showed a significant decrease ($p < 0.0001$) in AChE activity in the hippocampus and cortical region of brain of rotenone-toxified rats compared to the control. Rotenone-toxified rats post-treated with taxifolin showed a significant increase ($p < 0.0001$) in AChE activity. As shown in Fig. 4, post treatment with taxifolin has more effect on the hippocampus than the cortex.

Rotenone intoxication caused significant decrease ($p < 0.0001$) in GDH (Fig. 5a) and GS (Fig. 5b) activity compared with the control. This indicates that glutamate level increased in the cell and this can result in excitotoxicity. Rats treated with taxifolin showed a significant increase ($p < 0.0001$) in the activity of GDH and GS compared with untreated rats.

3.3 Taxifolin ameliorated oxidative stress in hippocampus and cortex of brain of rotenone-toxified rats

Oxidative stress is one of the main pathophysiological events implicated in rotenone neurotoxicity and pharmacological intervention that assuage oxidative stress could be considered a potential therapy. Hence, the effect of taxifolin to reduce oxidative stress was evaluated.

Oxidative stress elicited by rotenone administration in the hippocampus and cortex was mitigated by taxifolin post-treatment and is presented in Fig. 6(a-i). Taxifolin significantly ameliorated ($p < 0.0001$) the decreased level of GSH (Fig. 6a), and activity of antioxidant enzyme, GPx (Fig. 6b), SOD (Fig. 6c) and catalase (Fig. 6d), as well as reduced the level of FRAP (Fig. 6e) in hippocampus and cortex of rotenone-toxified rats. Rotenone intoxication caused increase in protein carbonylation (Fig. 6f) and lipid peroxidation was evoked (Fig. 6g), these were significantly abated ($p < 0.05$) by taxifolin post-treatment at all doses. Rotenone-toxified rats showed significant increase ($p < 0.0001$) in the level of nitric oxide

(Fig. 6h) and activity of xanthine oxidase (Fig. 6i) compared to control and were significantly reduced ($p < 0.0001$) by taxifolin post-treatment at all doses

3.4 MPO activity in rotenone-toxified rats was assuaged by taxifolin post-treatment

Inflammation is a key event in rotenone neurotoxicity and the ability of taxifolin to mitigate the initiation of inflammatory event was determined by evaluating the activity of MPO. Figure 7 showed a significant increase ($p < 0.0001$) in MPO activity in rotenone-toxified rats compared to control, which is indicative of inflammatory events. Taxifolin post-treatment at all doses caused a significant decrease ($p < 0.0001$) in the activity of MPO compared to untreated rats.

For the *in vivo* experiments, the test statistics of the One Way Analysis of Variance with all pairwise multiple comparison procedures done via Tukey Test were presented in Table 2.

3.5 Binding affinity and molecular interactions between taxifolin and targeted neurochemical enzymes

The involvement of TH, MAO, GS, as well as Na^+/K^+ -ATPase in neurotransmission is a reflective of the importance of neurotransmitter and neuronal membrane potential. *In silico* simulation was employed to check the interaction between these enzymes and taxifolin so as to ratify the pharmacological effect of taxifolin in abating neurotoxicity.

The *in silico* inhibitory mechanisms of taxifolin alongside some selected key enzymes implicated in neurotoxicity was evaluated through molecular docking. Molecular docking simulation showed that taxifolin modulated targeted enzymes *in silico*. Taxifolin showed a good binding affinity with targeted enzymes (Table 3). Taxifolin has the highest binding energy with TH (-9.8 kcal/mol), followed by GS (-9.0 kcal/mol). Na^+/K^+ -ATPase showed the lowest binding energy with taxifolin (-7.7 kcal/mol). This implies that taxifolin enhance the activity of TH and GS than the enzymes with low binding energy. Also, Table 3 showed the analysis of docking conformation and the important amino acid residue participating in molecular interaction in the complexes formed between our targeted enzyme and taxifolin. This indicated that hydrogen bond and hydrophobic interactions are the obvious intermolecular forces in these complexes (Fig. 8a-d).

Table 3

Binding affinity scores and molecular interaction analysis of taxifolin (Tax) docked against acetylcholinesterase (AChE), monoamine oxidase (MAO), Glutamine synthetase (GS), Tyrosine hydroxylase (TH) and Na⁺/K⁺-ATPase

Ligand-Protein Complexes	Binding Affinity (kcal/mol)	Residues forming H-bonds	Residues involved in H-bonds formation	Distances (Å)	Hydrophobic interacting residues
Tax-TH	-9.8	1	Asp 455	2.98	Phe 407, Pro 355, Pro 357, Leu 324, Trp 402, His 361, Phe 330 and Tyr 401
Tax-MAO	-7.8	1	Tyr 441	2.90	Gly 67, Tyr 407, Phe 352, Ile 180, Gln 215, Leu 337, Phe 208, Met 350, Ile 335 and Thr 336
Tax-GS	-9.0	7	His 253, Arg 340, Ser 320, Ala 321, Arg 299, Asn 248 and Lys 241	3.19 (2.92), 2.77, 3.13, 2.92, 3.25, 2.97 and 2.89	Trp 247, Gly 249, Arg 329 and Ser 307
Tax-Na ⁺ /K ⁺ -ATPase	-7.7	4	Thr 804, Glu 915, Lys 912 and Asp 891	3.10, 3.18(2.96), 2.80 and 2.76	Phe 790, Phe 793, Ile 322, Asn 129, Ile 325, Asp 128, Leu 132 and Leu 800
Tax-TH: Taxifolin-Tyrosine hydroxylase complex; Tax-MAO: Taxifolin-Monoamine oxidase complex; Tax-GS: Taxifolin-Glutamine synthetase complex; Tax-Na ⁺ /K ⁺ -ATPase: Taxifolin-Na ⁺ /K ⁺ -ATPase complex.					

4. Discussion

In this study, taxifolin increased mitochondrial complex I and Na⁺K⁺ ATPase activities, mitigated LDH activity and modulated neurotransmitter dysregulation. The oxidative stress evoked by rotenone intoxication was reduced by taxifolin in the hippocampus and cortex of the brain of rotenone-toxified rats. The involvement of hydrogen bond and hydrophobic interactions was notably documented as the two key molecular interaction between taxifolin and the targeted enzymes. The mechanism by which taxifolin exerted its therapeutic efficacy against rotenone neurotoxicity includes anti-oxidative, anti-inflammatory and, mitochondrial and neurotransmitter modulatory ability.

Polyphenols including taxifolin is able to perform their pharmacological and immunomodulatory activity due to their ability to donate electrons and hydrogen atoms by the functional groups in their structure (Procházková et al. 2011; Sandoval-Avila et al. 2019), for example, degree of hydroxylation of ring B and unsaturation degree of C₂ and C₃ double bond in the C-ring, are two structural features attributed to their beneficial role in combating brain injury (Wang et al. 2018). The biological activities of phytochemicals

has been demonstrated to depend upon their bio-accessibility and bioavailability in the brain in order to be an effective anti-inflammatory agent (Phan et al. 2018).

Rotenone, an inhibitor of complex I enzyme of the electron transport chain (ETC), has been reported to cause free-radical dependent oxidative injury and neurochemical dysfunction (Khadrawy et al. 2017). This study showed decrease in hippocampal and cortical complex I activity in rotenone-toxified rats. This results in mitochondrial dysfunction, caused bioenergetic defect and lead to cascade of pathologies that is ensued in rotenone neurotoxicity. The ameliorated activity of complex I by taxifolin in the present study may have a mitigating effect on other deleterious mechanism that rotenone intoxication may have elicited. Na^+K^+ ATPase is responsible for the generation of neuronal membrane potential through active efflux of Na^+ and influx of K^+ in the neuron. Na^+K^+ ATPase is an active enzyme that performs its activity through phosphorylation by ATP and thus, maintains neuronal excitability (de Lores Arnaiz and Ordieres 2014). Also, Na^+/K^+ ATPase is implicated in metabolic energy production and in the uptake, storage, and metabolism of neurotransmitters (Carageorgiou et al. 2007). Therefore, dysfunction in the activity of complex I that results to insufficient generation of ATP attenuated the activity of Na^+K^+ ATPase which was observed in the hippocampus and cortex of rotenone-toxified rats in this study.

Taxifolin was able to assuage this anomaly in rotenone-toxified rats. Furthermore, LDH activity has been employed as of cell membrane integrity indicator and to assess cell death in rotenone neurotoxicity (Elmazoglu et al. 2018). Incomplete oxidation of glucose is a metabolic consequence of complex I inhibition by rotenone and this subsequently caused lactic acid accumulation, as observed when LDH activity increased in this study. Mitochondrial dysfunction may consequently result to rotenone-induced cell death. In this study, hippocampal and cortical metabolic alterations as a consequence of rotenone intoxication was mitigated by taxifolin as revealed by decrease in LDH activity.

Dysregulation of dopamine metabolism was documented in the hippocampus and cortex region of brain in this study as a result of rotenone intoxication. Dysfunction of dopaminergic neuron or decrease in dopamine level causes motor (movement) disorder and depressive-like behavior of rats that are characteristics of neurodegenerative diseases. TH catalyzed the biosynthesis of L-DOPA (a precursor of dopamine) in a rate-limiting reaction in the brain. The level of L-DOPA is proportional to the concentration of dopamine availability in brain cells. Reports have demonstrated the role of TH in the pathogenesis of PD and other brain injury (Nakashima et al. 2013; Saliu et al. 2020). Also, dopamine can be deaminated by MAO to form catecholaldehyde and 3,4-dihydroxyphenylacetaldehyde, a cytotoxic intermediate which is can exacerbate neuronal injury (Goldstein et al. 2015).

In this study, taxifolin was able to alleviate dysfunction in dopamine metabolism, which result in increased dopamine bioavailability in the hippocampus and cortex of brain of rotenone-toxified rats. Acetylcholine is the main molecule in cholinergic system that is important in motor control and also, regulates cognitive functions. Neurotransmission in cholinergic system is terminated by AChE by hydrolyzing acetylcholine to acetate and choline. Decrease in AChE activity is observed in the hippocampus and cortex of the brain of rotenone-toxified rats in the present study and inhibition of AChE

activity has been reported to aggravate motor dysfunction in rotenone neurotoxicity (Abdel-Salam et al. 2014). Increase in hippocampal and cortical AChE activity by taxifolin could assuage motor, cognitive and memory impairment induced by rotenone toxicity.

It has been reported that mitochondrial dysfunction and excitotoxicity play an important role in the pathogenesis of rotenone-induced neurotoxicity. The mitochondrial dysfunction is induced by the inhibition of mitochondrial complexes I and predisposes motor neurons to ionotropic glutamate receptor-mediated excitotoxicity which ultimately caused death of motor neuron (Kanki et al. 2004). Glutamate excitotoxicity was evident in rotenone-toxified rats in this study. In metabolizing cell, GDH metabolizes glutamate to α -ketoglutarate while GS caused amidation of glutamate to glutamine with simultaneous hydrolysis of ATP. Excess glutamate in the cell is biochemically recycled in this manner to prevent accumulation of neurotoxic glutamate (excitotoxicity). Taxifolin markedly modulates the activity of GS and GDH in the hippocampus and cortex of rotenone-induced neurotoxicity in the present study. The action of taxifolin to mitigate oxidative stress and alleviate mitochondrial dysfunction may also enhance the activity of GS and GDH to attenuate glutamate excitotoxicity in taxifolin post-treated rats.

Oxidative stress has been demonstrated as a major pathology in neurotoxicity induced by rotenone. In rodents, subcutaneous exposure to rotenone increase the generation of reactive oxygen species in many brain regions such as cortex, hippocampus and striatum (Abdel-Salam et al 2013; Farombi et al. 2019). Glutathione is an endogenous non-enzymic antioxidant, which in its reduced form (GSH) along with other antioxidants, scavenge free radicals and protects the cells from oxidative injury, as well as maintains reduced intracellular homeostasis. Superoxides are free radical oxygen species that are produced constantly by metabolizing cells, especially in the brain and could turn reactive species when it is overwhelmingly produced and then caused oxidative stress. Superoxide dismutase catalyses the dismutation of the superoxide radicals into water and hydrogen peroxide, a non-radical reactive oxygen species while the hydrogen peroxide is further reduced by GPx and catalase into water and oxygen (Garcia-Sánchez et al. 2020; Hasanuzzaman et al. 2020).

Oxidative stress generated during rotenone intoxication as observed in this study could arise from metabolic consequence of mitochondrial dysfunction and incomplete glucose oxidation. More hydrogen peroxide is also produced when purines are broken down to uric acid in the cell by XO (Cristiana et al., 2014). The free radical produced leads to oxidative damage that caused protein carbonylation and consequently attacks membrane lipid.

Increment in NO level as seen in this study has been linked to altered neural development through reactive nitrogen species activation. Peroxynitrite, a potent oxidant, formed from the interaction between NO and superoxide modified proteins, lipids and DNA (Korhonen et al. 2005), this may be responsible for the increase in hippocampal and cortical protein carbonyl level and extent of lipid peroxidation, as well as increased NO level observed in this study. The abundance of polyunsaturated fatty acids, oxygen utilization, and high metabolic activity of the brain makes it susceptible to oxidative stress and a range of cellular dysfunctions (Akinmoladun et al., 2019). Also, oxidative stress can trigger the expression of

molecules that are involved in inflammatory pathology (Hussain et al., 2016), which is evidently seen in increase activity of MPO in this study.

The neurotoxic effect of rotenone on generating oxidative stress in the hippocampal and cortical region were markedly attenuated by taxifolin via restoration of level and activity of antioxidants (enzymic and non-enzymic), reduction of Fe (III) to Fe (II), scavenge reactive oxygen and nitrogen species and decrease NO level with consequent reduction in protein carbonylation and lipid peroxidation. Our study corroborated with other studies that reported the neuroprotective effect of taxifolin against diseases via attenuating oxidative injury (Tanka et al. 2019; Inoue et al. 2019). Taxifolin has been demonstrated to have anti-inflammatory property by scavenging reactive nitrogen species claimed to have elicited increased MPO activity (Rasak et al. 2018).

In the present study, the targeted enzymes selected for molecular docking simulation are enzymes involved in metabolism of neurotransmitters (TH and MAO for dopamine metabolism and GS for glutamate metabolism) and maintenance of membrane ionic gradient (Na^+/K^+ -ATPase). Dysfunction in the activity of these enzymes will cause dysregulation in neurotransmission and may ultimately leads to behavioral deficits. Interestingly, the binding energies from the molecular docking simulation in this study revealed that taxifolin effectively interacted with the targeted enzymes and thus modulated the activities of these enzymes. The non-covalent interactions (hydrogen bond and hydrophobic interaction) are the intermolecular forces that are crucial in the stability of ligand-protein complex (Ogunwa and Ayenitaju 2017; Stojanovi and Zari 2009) and also could be involved in the high binding energy values of the ligands (Mohapatra et al. 2015; Umar et al. 2020) observed in our current findings.

In conclusion, taxifolin exert therapeutic effect against metabolic and neurochemical modification in rotenone-induced neurotoxicity in rats via anti-oxidative, as well as mitochondrial and neurotransmitter modulatory activity, which is strongly supported by molecular docking and interaction of taxifolin with dopamine and glutamate metabolizing enzyme as well as Na^+/K^+ -ATPase. Noteworthy, the potentiality of taxifolin to exhibit the therapeutic activity highlighted in this study is associated to its structural features, such as its catechol structure in the B ring, saturated C_2 and C_3 bond in conjugation with a 4-oxo function in the C ring provides electron delocalization from the B ring and hydroxyl groups at positions 3 and 5 provides hydrogen bonding to the oxo group, thereby, cementing the notion of structure-function activity of flavonoids.

Declarations

Acknowledgement

The authors would like to thank Ms. F. A. Fadiji of Funmdek & Co. Integrated Solution (fisolution@yahoo.com) for assisting with the SPSS statistical analysis.

Funding

The authors did not receive support from any organization for the submitted work.

Competing interest

The authors have no conflict of interest to declare that are relevant to the content of this article.

Availability of data and material

All data generated or analyzed during this study are included in this published article and are also available from the corresponding author on reasonable request.

Code availability

Figures

Figure 1

Chemical structure depiction of taxifolin (PubChem ID: 439533)

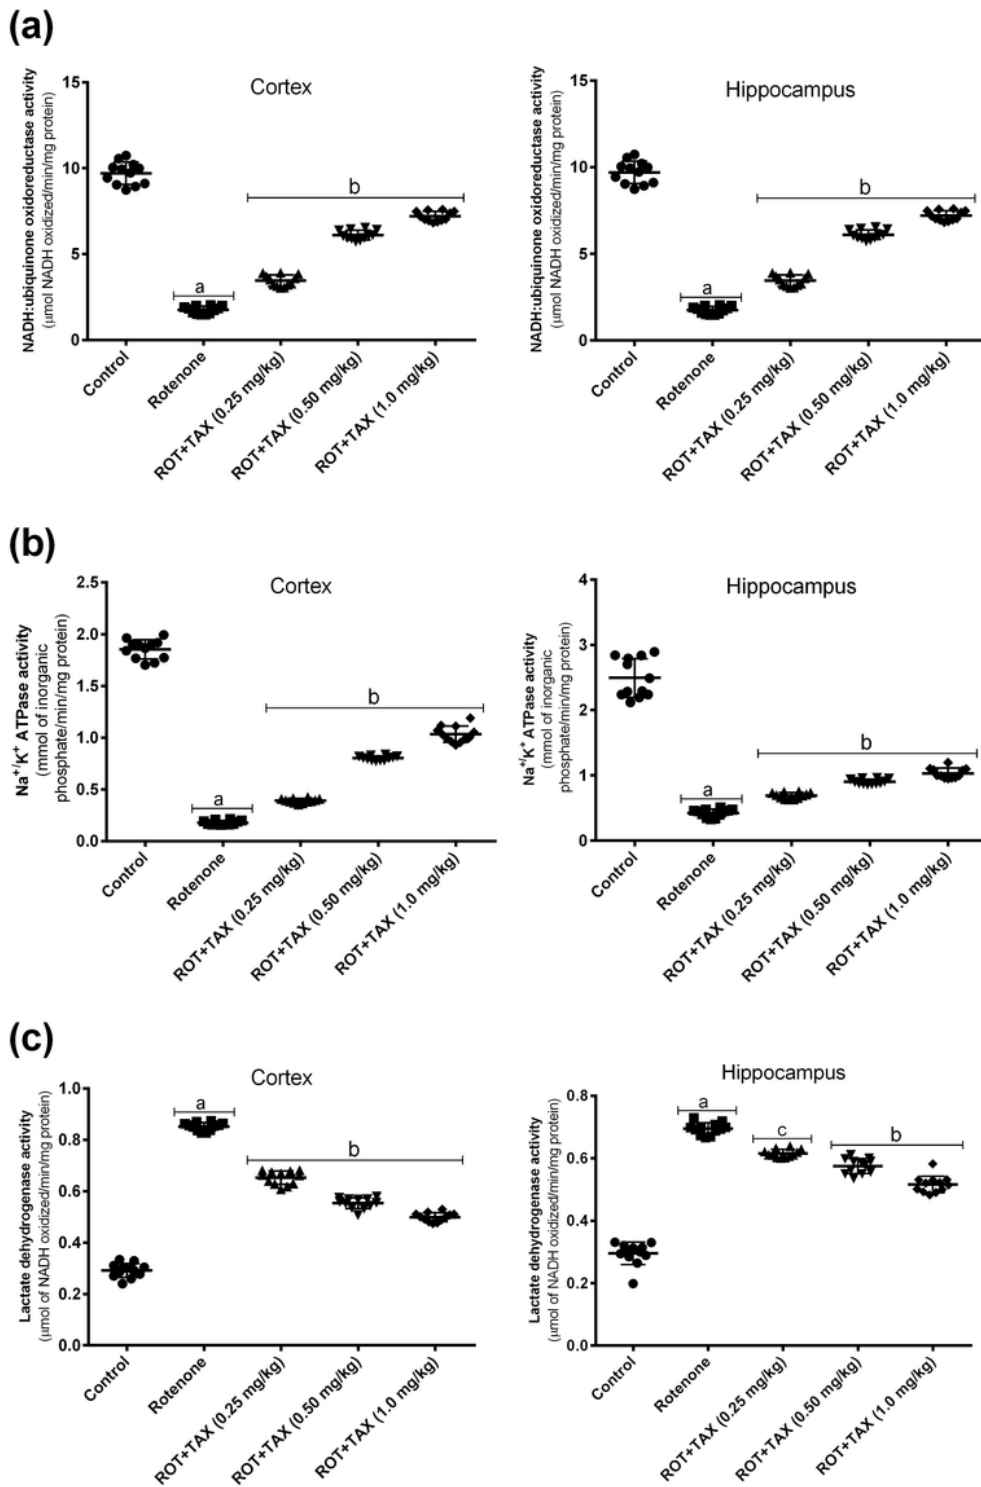

Figure 2

Effect of taxifolin on mitochondrial and neurochemical dysfunction in the hippocampal and cortical regions of brain of rotenone-toxified rats. (a) Complex I (NADH:Ubiquinone oxidoreductase) activity; (b) Na⁺/K⁺ ATPase activity; (c) lactate dehydrogenase (LDH) activity. Data are reported as mean ± standard deviation of the mean (SD) of twelve animals per group (one-way analysis of variance/Tukey's test). Bars with letter 'a' are significantly different at $p < 0.0001$ vs control. Bars with letter 'b and c' are significantly

different at $p < 0.0001$ and $p < 0.001$ vs rotenone, respectively. Control: rats only received corn oil as vehicle; Rotenone: rats administered with rotenone for 10 days; ROT + TAX (0.25, 0.5, 1.0 mg/kg): rats administered with rotenone for 10 days followed by 3-days post-treatment with taxifolin (0.25, 0.5, 1.0 mg/kg); ROT: Rotenone

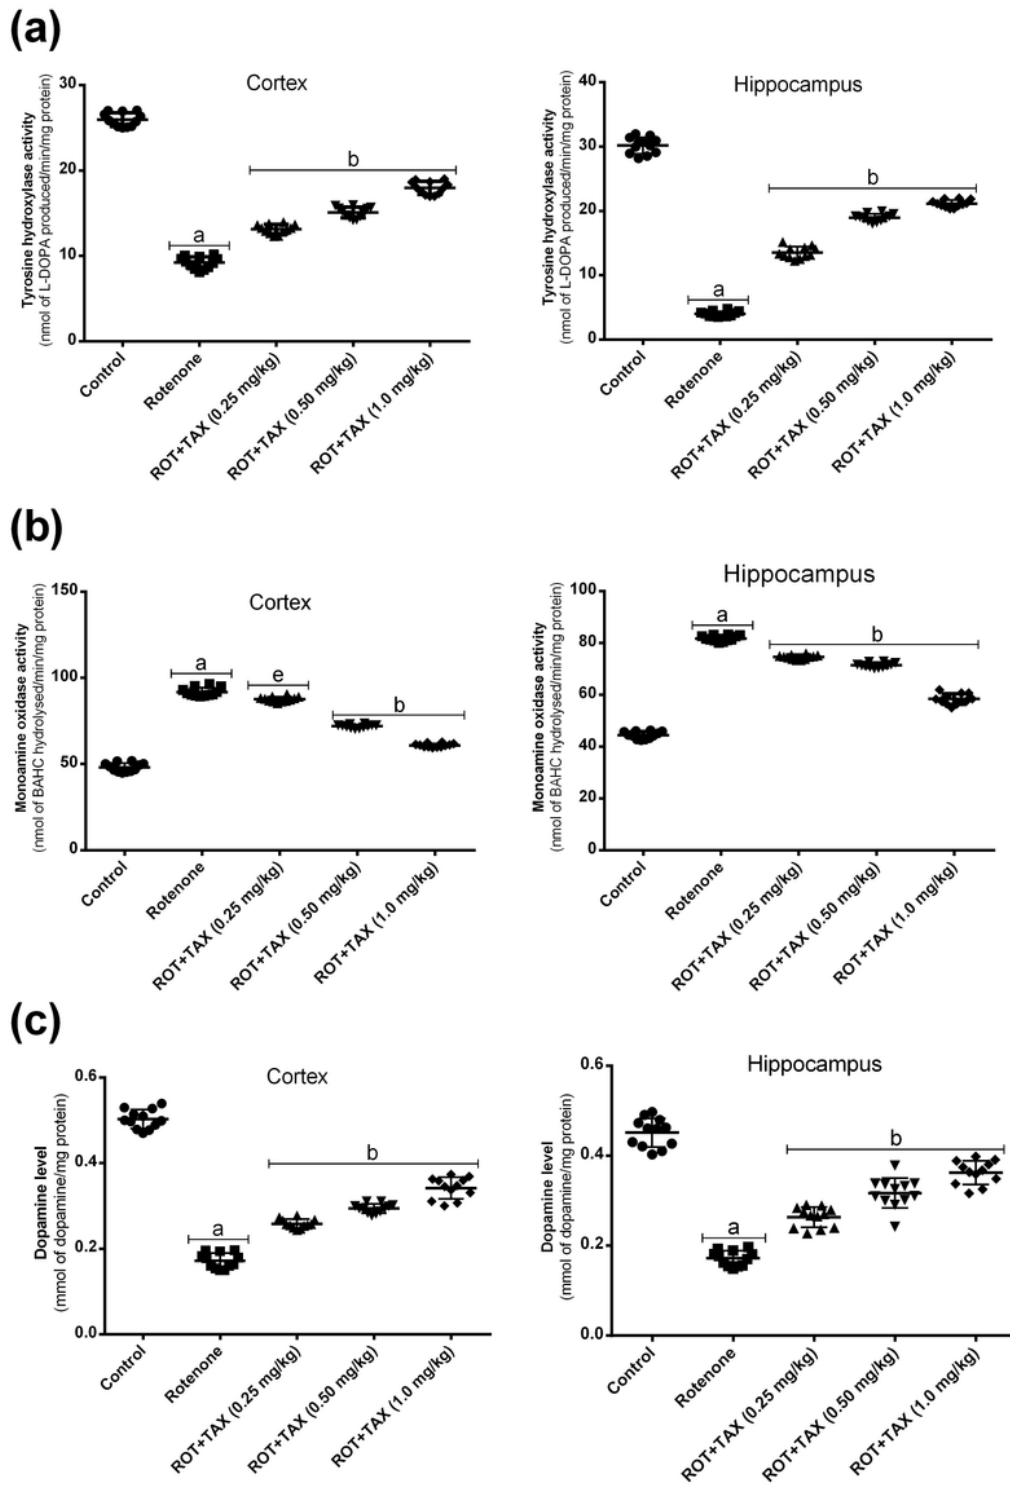

Figure 3

Effect of taxifolin on dopamine metabolism in the cortical and hippocampal region of brain of rotenone-toxified rats. (a) Tyrosine hydroxylase (TH) activity; (b) Monoamine oxidase (MAO) activity; (c) Dopamine level. Data are reported as mean \pm standard deviation of the mean (SD) of twelve animals per group (one-way analysis of variance/Tukey's test). Bars with letter 'a' are significantly different $p < 0.0001$ vs control. Bars with letter 'b' and 'e' are significantly different at $p < 0.0001$ and $p < 0.05$ vs rotenone, respectively. Control: rats only received corn oil as vehicle; Rotenone: rats administered with rotenone for 10 days; ROT + TAX (0.25, 0.5, 1.0 mg/kg): rats administered with rotenone for 10 days followed by 3-days post-treatment with taxifolin (0.25, 0.5, 1.0 mg/kg); ROT: Rotenone

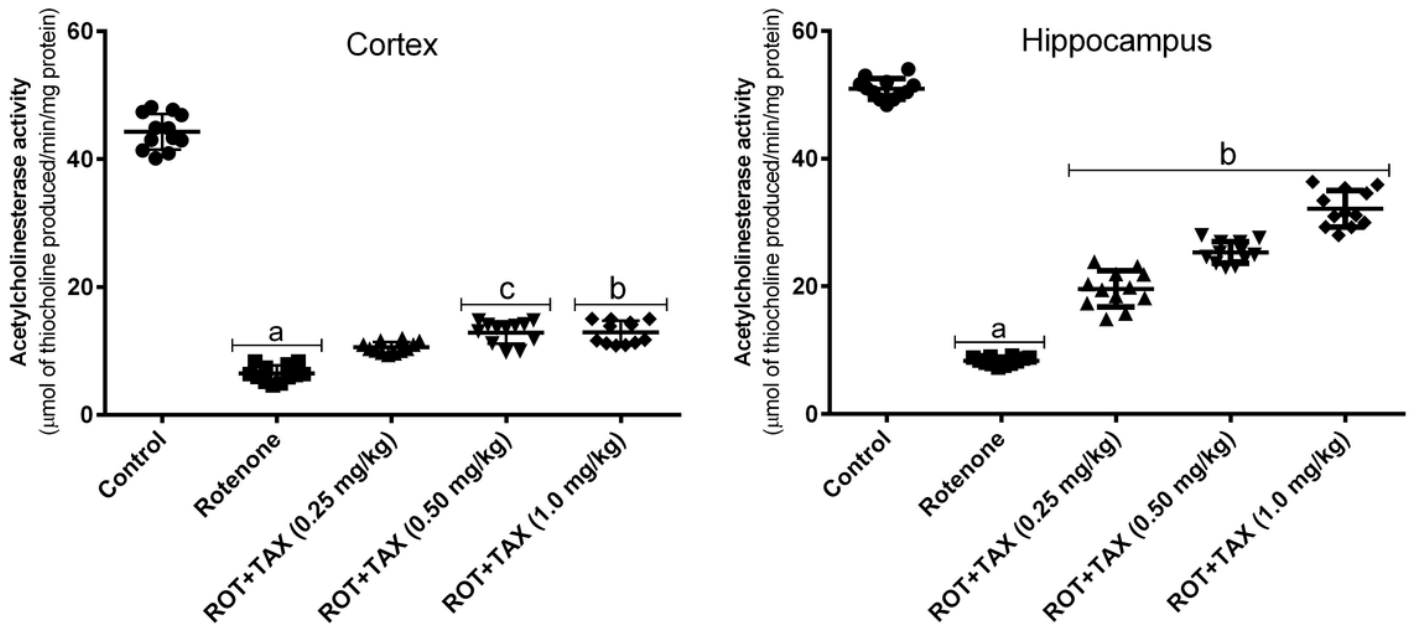

Figure 4

Effect of taxifolin on acetylcholinesterase (AChE) activity in the cortical and hippocampal region of brain of rotenone-toxified rats. Data are reported as mean \pm standard deviation of the mean (SD) of twelve animals per group (one-way analysis of variance/Tukey's test). Bars with letter 'a' are significantly different at $p < 0.0001$ vs control. Bars with letter 'b and c' are significantly different at $p < 0.0001$ and $p < 0.001$ vs rotenone, respectively. Control: rats only received corn oil as vehicle; Rotenone: rats administered with rotenone for 10 days; ROT + TAX (0.25, 0.5, 1.0 mg/kg): rats administered with rotenone for 10 days followed by 3-days post-treatment with taxifolin (0.25, 0.5, 1.0 mg/kg); ROT: Rotenone

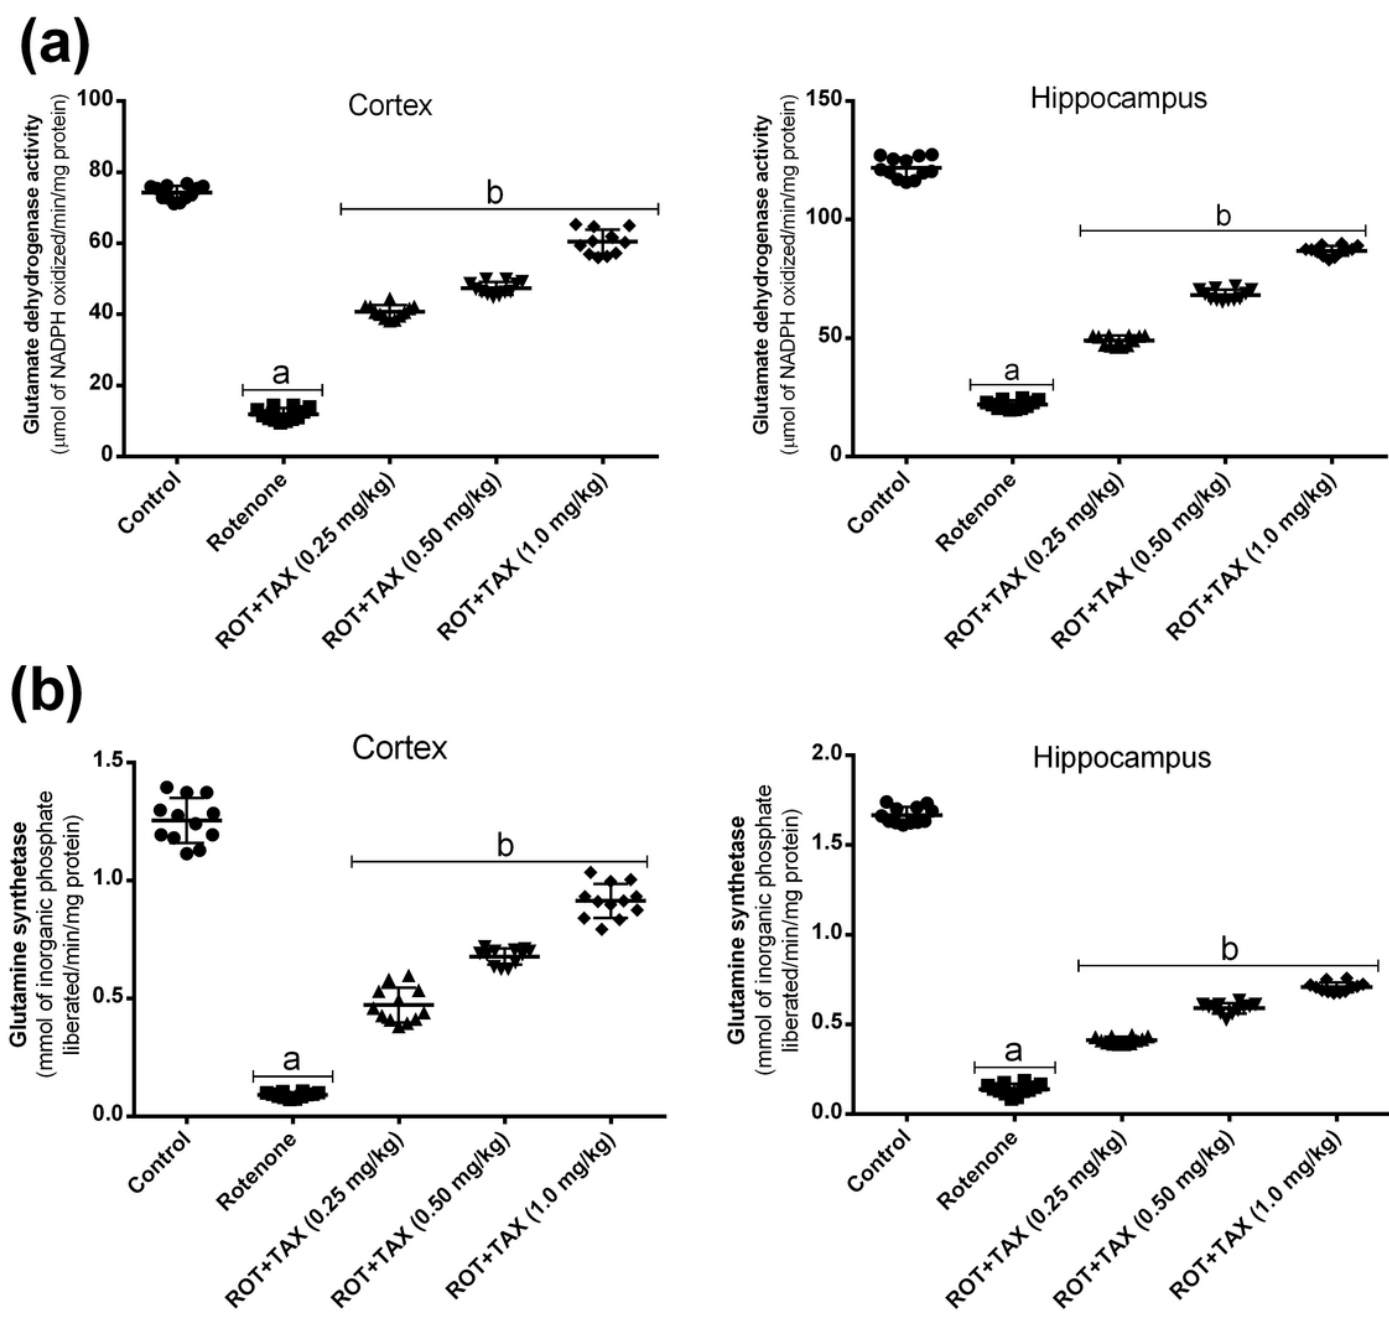

Figure 5

Effect of taxifolin on glutamate clearance in the cortical and hippocampal region of brain of rotenone-toxified rats. (a) Glutamate dehydrogenase (GDH) activity; (b) Glutamine synthetase (GS) activity. Data are reported as mean \pm standard deviation of the mean (SD) of twelve animals per group (one-way analysis of variance/Tukey's test). Bars with letter 'a' are significantly different at $p < 0.0001$ vs control. Bars with letter 'b' are significantly different at $p < 0.0001$ vs rotenone. Control: rats only received corn oil as vehicle; Rotenone: rats administered with rotenone for 10 days; ROT + TAX (0.25, 0.5, 1.0 mg/kg): rats administered with rotenone for 10 days followed by 3-days post-treatment with taxifolin (0.25, 0.5, 1.0 mg/kg); ROT: Rotenone

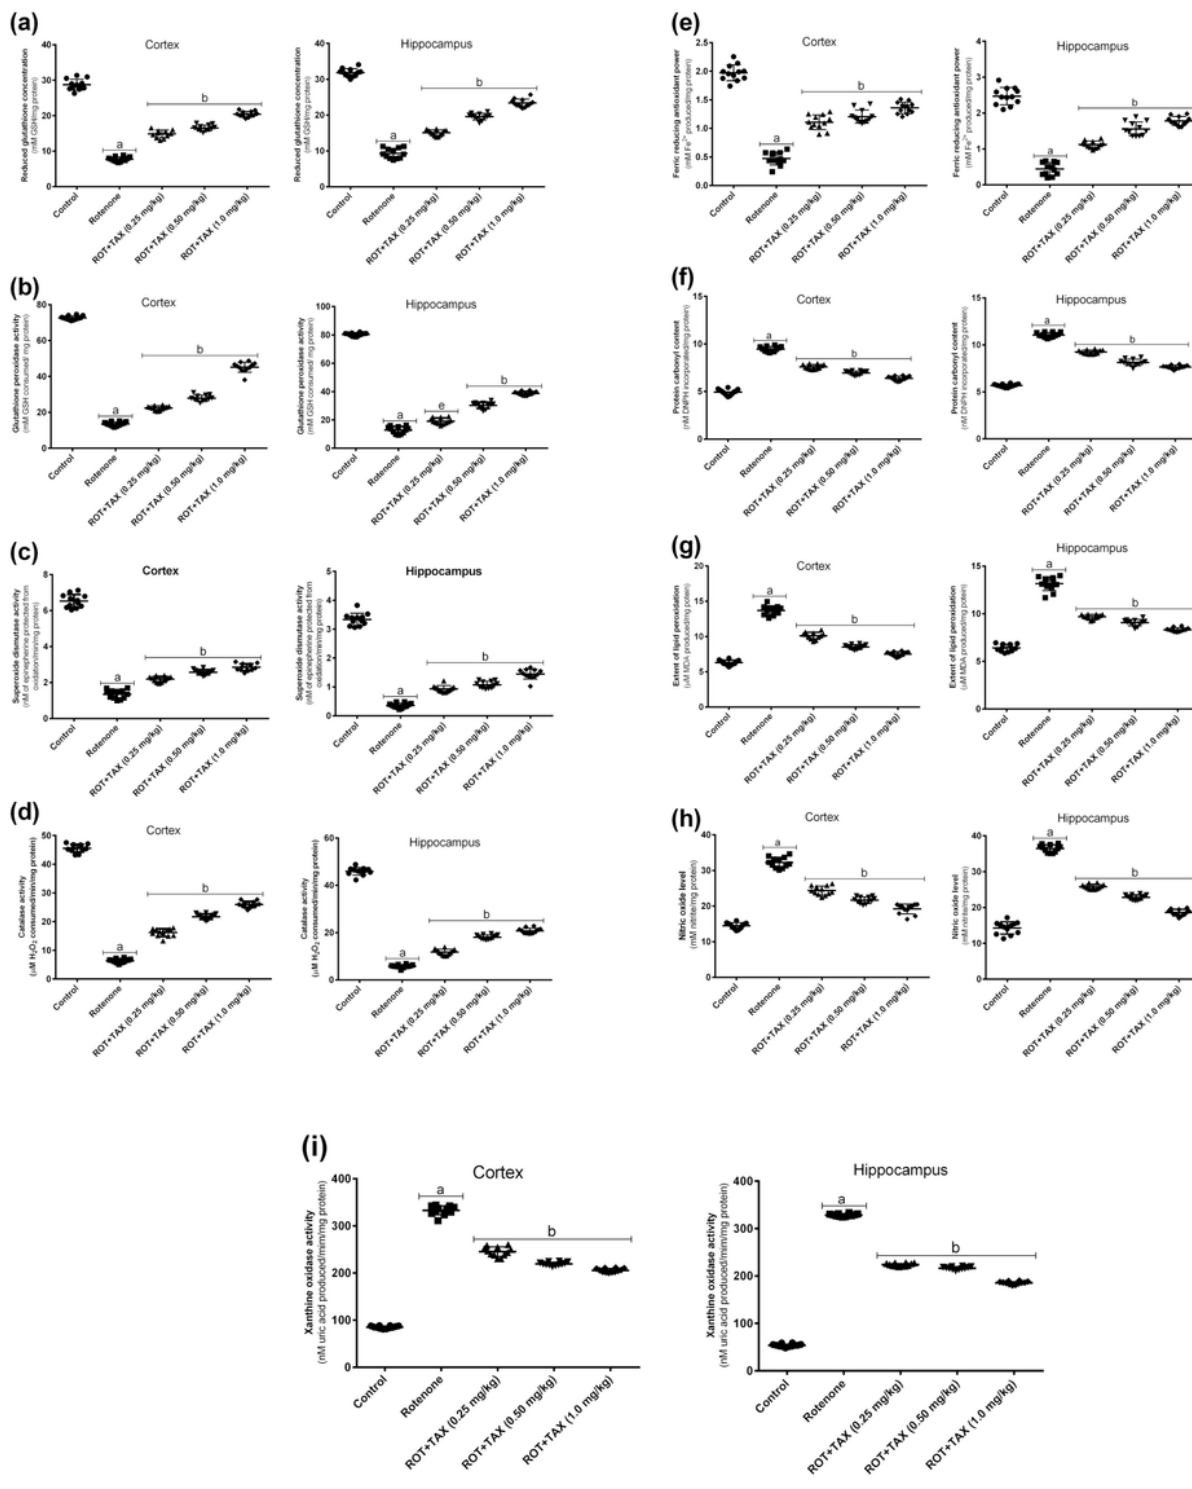

Figure 6

Effect of taxifolin on oxidative stress markers in the cortical and hippocampal region of brain of rotenone-toxified rats. (a) Reduced glutathione (GSH) activity; (b) Glutathione peroxidase (GPx) activity; (c) Superoxide dismutase (SOD) activity; (d) Catalase activity; (e) Ferric reducing antioxidant power (FRAP) level; (f) Protein carbonyl level; (g) Lipid peroxidation (TBARS); (h) Nitric oxide (NO) level. (i) Xanthine oxidase (XO) activity. Data are reported as mean \pm standard deviation of the mean (SD) of

twelve animals per group (one-way analysis of variance/Tukey's test). Bars with letter 'a' are significantly different $p < 0.0001$ vs control. Bars with letter 'b' and 'e' are significantly different at $p < 0.0001$ and $p < 0.05$ vs rotenone, respectively. Control: rats only received corn oil as vehicle; Rotenone: rats administered with rotenone for 10 days; ROT + TAX (0.25, 0.5, 1.0 mg/kg): rats administered with rotenone for 10 days followed by 3-days post-treatment with taxifolin (0.25, 0.5, 1.0 mg/kg); ROT: Rotenone.

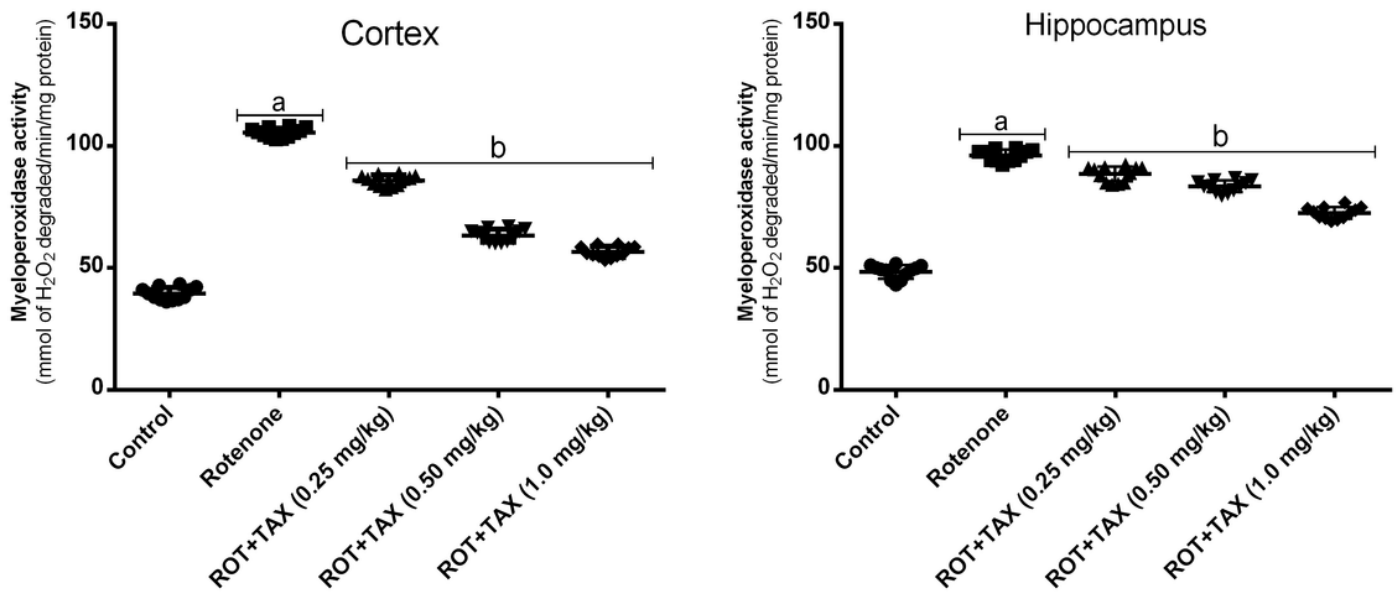

Figure 7

Effect of taxifolin on myeloperoxidase (MPO) activity in the cortical and hippocampal region of brain of rotenone-toxified rats. Data are reported as mean \pm standard deviation of the mean (SD) of twelve animals per group (one-way analysis of variance/Tukey's test). Bars with letter 'a' are significantly different $p < 0.0001$ vs control. Bars with letter 'b' are significantly different at $p < 0.0001$ vs rotenone. Control: rats only received corn oil as vehicle; Rotenone: rats administered with rotenone for 10 days; ROT + TAX (0.25, 0.5, 1.0 mg/kg): rats administered with rotenone for 10 days followed by 3-days post-treatment with taxifolin (0.25, 0.5, 1.0 mg/kg); ROT: Rotenone

Figure 8

Binding conformation (3D) of taxifolin when docked with some selected enzymes linked to neurotoxicity. (a) Tax-TH complex, TH (brown cartoon) with taxifolin (green) bind to its active site domain and 2D molecular interaction of taxifolin with amino acid residues that reside within the catalytic domain of TH; (b) Tax-MAO complex, MAO (gold cartoon) with taxifolin (green) bind to its active site domain and 2D molecular interaction of taxifolin with amino acid residues that reside within the catalytic domain of MAO; (c) Tax-GS complex, GS (cyan cartoon) with taxifolin (blue) bind to its active site domain and 2D molecular interaction of taxifolin with amino acid residues that reside within the catalytic domain of GS; (d) Tax- Na⁺/K⁺ ATPase complex, Na⁺/K⁺ ATPase (purple cartoon) with taxifolin (gold) bind to its active site domain and 2D molecular interaction of taxifolin with amino acid residues that reside within the catalytic domain of Na⁺/K⁺ ATPase. Green dashes and red curved spikes in the 2D plots represent hydrogen bonds and hydrophobic interactions, respectively. The molecular docking experiment was executed using auto dock vina, PyMOL and LigPlot software.
