Abstract

Background Unintended pregnancy is an important public health problem in Ethiopia. It causes adverse physical, mental, social and economic outcomes. Identifying factors associated with unintended pregnancy may help to reduce unintended pregnancy and hence adverse outcomes. There are few studies about the prevalence and associated factors of unintended pregnancy in Ethiopia. But these studies were based on few sample size and fragmented. Therefore, this analysis was done to identify factors associated with unintended pregnancy in Ethiopia based on nationally representative data.

Methods The study used the 2016 Ethiopian demographic and health survey data. The data was downloaded from The DHS program with permission. A total of 1135 women were included in the final model. Data was weighted to consider disproportionate sampling and non-response. Multivariable logistic regression was used to identify factors associated with unintended pregnancy among women.

Result About 30% (95% CI: 25.33 -34.39) pregnancies were unintended. Married women (AOR; 0.34; 95% CI: 0.01- 0.14), woman living in developing regions (AOR; 0.14; 95% CI: 0.07- 0.27) and women who reported distance not a big problem to get medical care (AOR 0.59; 95% CI: 0.36 - 0.99) had lower odds of unintended pregnancy. On the other hand, multi-para (AOR; 3.77; 95% CI: 1.71 - 8.33), grand multi-para (AOR; 6.72; 95% CI: 2.74 - 16.49) women and women who ever used contraceptives (AOR; 1.86 95% CI: 1.06 - 3.26) had higher odds of unintended pregnancy.

Conclusion Although high, the magnitude of unintended pregnancy in Ethiopia was lower compared to the global level. Marital status, region, perceived distance to seek medical care, parity and history of contraceptive use were found significant predictors of unintended pregnancy in Ethiopia.

Introduction

Unintended pregnancy, defined as pregnancy that is reported as either unwanted (pregnancy that occurred when no more child was desired) or mistimed (pregnancy that occurred earlier than the desired time), is a global problem that affected the health of women, families and relatives. Unintended pregnancy occurs due to non-use or inconsistent uses of contraceptives or method failure (1, 2).

Globally, 44% pregnancies were unintended. From 1990 to 2014, the rate of unintended pregnancy decreased by 30% in developed regions but only 16% in developing regions. Unintended pregnancy accounted for 65% of all pregnancies in developing countries. About 59% of this pregnancy ends with abortion. Annually 302,000 mothers die due to pregnancy related complications in developing countries. Sub-Saharan African countries accounted for 66% of all maternal deaths. Unsafe abortion was among the main cause of maternal death in the Sub-Sahara region (2–4). About 1.9 million and 620,300 Ethiopian women had unintended pregnancy and abortions every year respectively. It represents an annual rate of 28 abortions per 1000 women age 15 to 49 years (5–7).

Studies conducted in Kenya, Egypt, Nigeria and South Africa indicated that the prevalence of unintended pregnancies was 24%, 30.7%, 35.9% and 64.33% respectively (8–11). According to studies conducted in different parts of Ethiopia, the prevalence of unintended pregnancy ranged from 13.7% to 41.5% (12–19).

Studies conducted in different African countries identified that age, place of residence, marital status, ethnicity, types of employment, educational status, numbers of living children, monthly income and women autonomy, parity, gravidity, knowledge on contraceptives, accessibility of contraceptives as determinants of unintended pregnancy (8–11, 20). Similarly, studies conducted in various parts of Ethiopia identified age, residence, religion, marital status, parity, visiting health professionals, history of abortion, age at first birth, family size, educational status, gravidity, distance from health facility, history of still birth and knowledge on modern contraceptive methods as determinants of unintended pregnancy (12–19).

Despite improvements on contraceptive use, the level of unintended pregnancy showed slight decline in Ethiopia. Ethiopia planned to end all preventable cause of maternal mortality in 2030. Preventing unintended pregnancy is one of the key intervention areas to minimize maternal mortality. However, with the existing high level of unintended pregnancy, it is difficult to achieve this target in 2030 (20–23).

There are few studies about prevalence and associated factors of unintended pregnancy in Ethiopia. But these studies were fragmented and based on small number of study participants. Therefore, this analysis was done to identify the prevalence and factors associated with unintended pregnancy in Ethiopia based on nationally representative data.

Methods

Data

We used the 2016 EDHS data for this analysis. The 2016 EDHS is a community based cross sectional survey collected from January 18 to June 25, 2016. The survey was designed to provide key indicators at national and regional level. The survey used a two-stage stratified random sampling technique. First, each region was stratified into rural and urban areas. Then, enumeration areas (EA) were selected with probability proportional to enumeration area size. After this, household listing in the selected EAs was done. In the second stage, a fixed number of 28 households from each cluster were selected and included using systematic random sampling technique. In both surveys, women aged 15–49 who were either permanent residents of the selected households or visitors who stayed in the household the night before the survey were interviewed. Interviewer administered questionnaire was used to collect data. The details of the methodology; sampling technique, data collection and data quality assurance are available from EDHS reports (24). A total of 15,683 reproductive age women were included in the survey. From these, 1135 pregnant women were included in the analysis.

Measurement

The outcome variable for this analysis was unintended pregnancy, which had two categories (yes or no). The 2016 EDHS questionnaire asked all reproductive age women involved in the survey whether they were pregnant or not at the time of survey. If the woman responded she was pregnant, then she was asked if the pregnancy was wanted, wanted later or not wanted at all. When the woman reported the pregnancy was wanted at the time of survey, the outcome variable was considered “no”. On the other hand, if the woman reported the pregnancy was wanted later or was not wanted at all, the outcome variable was considered unintended and coded “yes”.

The dependent variables included in this analysis were socio-demographic (age, educational status, marital status, household wealth index, residence, religion, working status of the woman and region), reproductive health (parity, history of abortion, history of previous contraceptive use and knowledge of contraceptives), health service related (distance to health facility to seek medical care) and woman autonomy related variables (can refuse sex, refusing sex is justified if she suspect STI).

Analysis

We used STATA software for this analysis. The data were weighted to adjust for over sampling or under-sampling and non-response. Descriptive statistics were calculated for all variables. Correlation between independent variables was checked before fitting the final regression model. Multivariable logistic regression analysis was done to identify factors associated with unintended pregnancy. When two independent variables were found correlated, one was dropped. In addition, complex survey analysis techniques were employed when computing odds ratios since DHS used a two-stage stratified sampling technique.

Results

Background characteristics of pregnant women

Five hundred fifty five (48.93%) women were in the age range of 25 to 34 years. Six hundred three (53.20%) respondents reported that they didn't attend formal education. Two hundred fifty seven (22.67%) participants were from households with the poorest wealth index. Majority of the respondents (96.59%) were married or living in union. Nine hundred seventy four (85.83%) respondents were rural residents. About three-fourth of these pregnant women were not working at the time of the survey (table 1).

Reproductive health characteristics of pregnant women

Four hundred fifty six (40.23%) mothers were multi-para. One thousand twenty five (90.33%) respondents haven no history of abortion. Six hundred seventeen (54.37%) respondents had never used contraceptives. Six hundred thirty five (56.01%) respondents reported distance was a big problem to get medical care. Six hundred fifty two (57.51%) respondents reported that they would not refuse sex when

the husband request. One thousand one hundred six (97.49%) respondents were knowledgeable about contraceptives (table 2).

Prevalence of unintended pregnancy

The magnitude of unintended pregnancy in Ethiopia was 29.66% (95% CI, 25.33 – 34.39). Unintended pregnancy was high in Oromia region and low in Harari region.

Unintended pregnancy by characteristics of women

One hundred sixty nine (50.36%) respondents among women who have unintended pregnancy and 387(48.38%) respondents among women who haven't unintended pregnancy was in the age groups of 25 to 34 years. One hundred ninety (56.69%) respondents women's who have unintended pregnancy and 414(51.74%) respondents among women's who haven't unintended pregnancy did not attained formal education while only 27 (7.81%) respondent among women who have unintended pregnancy and 108 (13.44%) respondents among women's who haven't unintended pregnancy did attained secondary or higher education. Three hundred eight (91.63%) respondents among women who have unintended pregnancy and 666(83.38%) respondents among women's who haven't unintended pregnancy was lived in rural residence (Table 3).

Factor associated with unintended pregnancy in Ethiopia

On the multivariable analysis, marital status, region, perceived distance from health facility to get medical care, parity and history of contraceptive use were found significantly associated with unintended pregnancy.

Women who were married had 66% lower odds to have unintended pregnancy compared to women who were single, divorced and widowed (AOR; 0.34; 95% CI: 0.01 – 0.14). Women who were living in developing regions were 84% less likely to have unintended pregnancy compared to women who were living in major regions (AOR; 0.14, 95% CI: 0.07 – 0.27). Women who reported distance to health facility was not a big problem to get medical care were 41% (AOR 0.59; 95% CI: 0.36 - 0.99) less likely to have unintended pregnancy compared to those who reported distance was a big problem to seek medical care (Table 4).

The odds of having unintended pregnancy among multi-para and grand multi-para women was 3.77 (95% CI: 1.71 - 8.33) and 6.72 (95% CI: 2.74 - 16.49) respectively times higher compared to nulli-para women. Similarly, women who ever had used contraceptives had 1.86 (95% CI: 1.06 - 3.26) times higher odds of having unintended pregnancy compared to those who never used (Table 4).

Discussion

The prevalence of unintended pregnancy in the study area was 29.66% (95% CI: 25.33 - 34.39). The finding of this study was in line with studies conducted in Maichew Ethiopia (17), Addis Zemen, Ethiopia (18) and

Egypt(9). However the finding was lower than studies conducted in Arsi Negele and Jimma Ethiopia (12, 14), Nigeria(10) and South Africa(11). This might be due to the low contraceptive prevalence rate in Nigeria compared to Ethiopia (25–27). The difference compared to the study in South Africa might be the difference in the proportion of married women in these studies; only 36% sexually active women were married or living in union in South Africa compared to 65% in Ethiopia(27, 28).The presence of unmarried sexually active women may increase the risk of unintended pregnancy.The finding of this study was higher than study conducted in Belesa Ethiopia, Addis Zemen Ethiopia (16, 18) and Kenya(8). This might be due to difference in the study area. The difference compared to the study in Kenya might be high contraceptive prevalence rate in Kenya compared to Ethiopia(29).

Married or in union women had lower odds of having unintended pregnancy.This finding was consistent with studies conducted in Ethiopia(15, 19), South Africa(11) and Kenya(8). This may be due to the value of community on marriage and fear of social stigma on having child outside of marriage(30). In addition, women may fear to face economical burden for rearing the baby alone(31).

Mothers who live in developing regions had lower odds of having unintended pregnancy compared to those living in major regions. This finding was consistent with a study conducted in Ethiopia(32). The reason for this might, low demand for family planning in developing region (Afar, Somali, Benshangul Gumuz and Gambela) (27). Moreover, fertility preference among women in these regions was higher compared to those in other regions (33).

Mothers who reported distance was not a big problem to seek medical care had 41% lower odds of having unintended pregnancy compared to women who reported distance as a problem. This finding was consistent with studies conducted in Ethiopia(15, 34).This might be related to access to family planning services. When women did not perceive distance as a problem, they may tend to use contraceptives (35). In addition, it increases the indirect cost of the family planning service utilization like transportation cost and lost from other productive activities(36, 37).

Multi-para women had higher odds of having unintended pregnancy compared to nulli-para women. This finding was consistent with studies conducted in Addis Zemen(18), Arsi Negele Woreda(12) and Debre Brhan town(15) and Kenya (8). The reason for this is that fertility preference among multipara women is lower than nulli-para. Therefore, the pregnancy among multi-para women is more likely to be unintended.

Women who ever used contraceptives had higher odds of having unintended pregnancy compared to their counterparts. The finding of this study was in line with studies conducted in Ivory Coast(38) but contradict with study in Legabo Woreda, North East Ethiopia (39). The reason for this may be women who ever used contraceptives were not using it just before the pregnancy occurred. In addition, women who ever used contraceptives may have experienced side effects and declined to use (40). Method failure may be the other reason for unintended pregnancy. Social desirability bias may have affected the results of this study. Many women in Ethiopia rationalize the pregnancy and report as intended although the pregnancy was mistimed or unintended.

Conclusions

Although still high, the magnitude of unintended pregnancy in Ethiopia was lower compared to the global prevalence. Marital status, living in developing regions, perceived distance to seek medical care, parity and history of modern contraceptive use were found predictors of unintended pregnancy. Unintended pregnancy prevention efforts should be strengthened among unmarried and multi-para women. Further study is needed to evaluate the quality of family planning programs since women who have ever used had more odds of unintended pregnancy in this study.

Declarations

Ethics approval and consent to participate

The 2016 EDHS protocol was reviewed and approved by the National Ethics Review Committee of the Federal Democratic Republic of Ethiopia, Ministry of Science and Technology and the Institutional Review Board of ICF International. The STATA format data was downloaded from the DHS program with permission.

Consent for publication

Not applicable

Availability of data and material

Upon request, the data is available on The DHS program website at <https://www.dhsprogram.com/data/available-datasets.cfm>

Competing Interests

The authors declare that there is no conflict of interest.

Funding

No external fund was received for this analysis

Authors' contributions

Y. A.B initiated and performed the analysis and prepared the manuscript. GAF involved equally in the analysis and preparation of the manuscript. All authors read and approved the final manuscript.

Acknowledgments

The author would like to thank the DHS program for allowing to use the data.
