Abstract

Background: Increases in resistance to fluoroquinolones have been correlated with the use of levofloxacin in the treatment of infections caused by *Escherichia coli*. The analysis presents the in vitro activity of ceftazidime-avibactam and comparator agents against 10,840 levofloxacin-resistant *E. coli* isolates collected from four geographic regions (Africa/Middle East, Europe, Asia/South Pacific, Latin America) between 2012 and 2018.

Methods: Non-duplicate clinical isolates of *E. coli* were collected from participating centres and shipped to International Health Management Associates, Inc. [IHMA], Schaumburg, IL, USA. Susceptibility testing was performed with frozen broth microdilution panels manufactured by IHMA, according to CLSI guidelines. Levofloxacin-resistance was defined at a minimum inhibitory concentration of ≥ 2 mg/L. Isolates collected between 2012 and 2015 were tested for extended-spectrum β -lactamase (ESBL) activity by determining susceptibility to cefotaxime, cefotaxime-clavulanate, ceftazidime, and ceftazidime-clavulanate as recommended by CLSI guidelines. Isolates collected between 2016 and 2018 were identified as ESBL-positive by genotype using multiplex polymerase chain reaction assays.

Results: A total of 74.8% of levofloxacin-resistant *E. coli* isolates in the analysis were from three culture sources: urinary tract infections (N = 3,229; 29.8%), skin and skin structure infections (N = 2,564; 23.7%) and intra-abdominal infections (N = 2,313; 21.3%). Susceptibility rates to ceftazidime-avibactam were consistently high in all regions against both ESBL-positive (97.0% in Asia/South Pacific to 99.7% in Africa/Middle East and Latin America) and ESBL-negative isolates (99.4% in Asia/South Pacific to 100% in Latin America). Susceptibility was also high in each region among ESBL-positive and ESBL-negative isolates to colistin ($\geq 98.5\%$), imipenem ($\geq 96.5\%$), meropenem ($\geq 96.5\%$) and tigecycline ($\geq 94.1\%$).

Conclusions: Antimicrobial susceptibility to ceftazidime-avibactam among levofloxacin-resistant *E. coli* isolates, including ESBL-positive isolates, collected from four geographical regions between 2012 and 2018 was consistently high. Susceptibility to the comparator agents colistin, tigecycline, imipenem and meropenem was also high.

Background

The frequency of antimicrobial resistance has increased worldwide, and has been associated with the inappropriate use of antimicrobials [1]. Fluoroquinolones, which have high bioavailability, oral administration and good tissue distribution [2], are commonly used agents; however, increases in resistance to fluoroquinolones have been correlated with the use of levofloxacin in the treatment of infections caused by *E. coli* [3]. Resistance to fluoroquinolones often arises by mutations in the drug targets, DNA gyrase and DNA topoisomerase IV [4, 5], and a frequency of > 20% resistance to fluoroquinolones among uropathogens, including *E. coli* has been reported [6, 7]. The availability of treatment options is further complicated in infections caused by members of the Enterobacterales as

resistance to fluoroquinolones has been associated with extended-spectrum β -lactamases (ESBLs) positive isolates, and ESBL production is associated with the hydrolysis of penicillins and β -lactams, including third-generation cephalosporins [8–10]. ESBL-producing bacteria are now pervasive worldwide, and according to one estimate, over 1.5 billion people are colonised with ESBL-producing Enterobacterales [11].

Avibactam is a diazabicyclooctane, non- β -lactam, β -lactamase-inhibitor, and the combination of ceftazidime with avibactam possesses in vitro activity against Enterobacterales carrying β -lactamases of Ambler class A (ESBLs and *Klebsiella pneumoniae* carbapenemases), class C (AmpC cephalosporinases) and some class D (e.g. OXA-48-type, many of which co-carry ESBLs) [12–16]. The in vitro activity of ceftazidime-avibactam and a panel of comparator agents has been tracked via the International Network for Optimal Resistance Monitoring (INFORM) surveillance program, which was established in 2012, and the Antimicrobial Testing Leadership and Surveillance (ATLAS) study [17], which succeeded INFORM.

The data presented here describe the in vitro activity of ceftazidime-avibactam and comparator agents against ESBL-positive and ESBL-negative levofloxacin-resistant *E. coli* isolates collected from four geographic regions (Africa/Middle East, Europe, Asia/South Pacific, Latin America) between 2012 and 2018.

Materials And Methods

Bacterial isolates

Non-duplicate clinical isolates of *E. coli* were collected from participating centres in Africa/Middle East, Asia/South Pacific, Europe and Latin America between 2012 and 2018. Following their shipment to the central reference laboratory (International Health Management Associates, Inc. [IHMA], Schaumburg, IL, USA), samples were identified using matrix-assisted laser desorption ionization-time of flight (MALDI-TOF) mass spectrometry (Bruker Biotyper, Bruker Daltonics, Billerica, MA, USA).

Susceptibility testing

Susceptibility testing was performed with frozen broth microdilution panels manufactured by IHMA, according to CLSI guidelines [18]. Avibactam was tested at a fixed concentration of 4 mg/L in combination with doubling dilutions of ceftazidime (testing range, ≤ 0.015 mg/L–128 mg/L). MICs were interpreted using EUCAST 2020 breakpoints, version 10.0 [19], and resistance to levofloxacin was defined as a minimum inhibitory concentration (MIC) of ≥ 2 mg/L. Isolates collected between 2012 and 2015, with MICs of ≥ 2 mg/L to ceftazidime or aztreonam, were tested for ESBL activity by determining susceptibility to cefotaxime, cefotaxime-clavulanate, ceftazidime, and ceftazidime-clavulanate as recommended by CLSI guidelines [20]. Isolates collected between 2016 and 2018 with MICs ≥ 2 mg/L to meropenem, ceftazidime or aztreonam were screened for β -lactamase genes, using multiplex polymerase chain reaction assays, and ESBL-positive isolates were identified by genotype [21]. All detected β -

lactamase genes, excluding original spectrum β -lactamases were amplified using flanking primers and sequenced. Sequences were compared against publicly available databases.

Statistical analyses

The Cochran-Armitage Trend Test was used to assess changes over the study years in the proportion of levofloxacin-resistant *E. coli* isolates that were identified as ESBL-positive. A p-value of < 0.01 was interpreted as statistically significant as the n values in the analysis were high and therefore the test was likely to be over-powered. Analyses were performed with SAS® version 9.4 (SAS Institute Inc., Cary, NC, USA).

Results

Distribution of levofloxacin-resistant *E. coli* isolates

A total of 10,840 isolates collected from four geographic regions and identified as resistant to levofloxacin were included in the analysis. Isolates were most commonly collected from UTIs (N = 3,229; 29.8%), followed by 2,564 (23.7%) from skin and skin structure infections, 2,313 (21.3%) from intra-abdominal infections, 1,482 (13.7%) from lower respiratory tract infections, and 1,204 (11.1%) from bloodstream infections, whilst 48 (0.4%) were from an unknown or other source. A similar distribution was observed among ESBL-positive and ESBL-negative isolates (data not shown).

The highest proportion of isolates were collected from Europe (N = 4,663; 43.0%). The proportion of isolates collected from Latin America (N = 2,699; 24.9%) and Asia/South Pacific (N = 2,337; 21.6%) were similar, and a minority were from Africa/Middle East (N = 1,141; 10.5%).

Analysis of regions combined against levofloxacin-resistant *E. coli*

Table 1 shows the in vitro activity of ceftazidime-avibactam and comparators against levofloxacin-resistant ESBL-positive and ESBL-negative *E. coli* when data from all regions of collection were combined. Rates of susceptibility to ceftazidime-avibactam and colistin were similar ($\geq 99.0\%$) in both sets of isolates. Other comparator agents with high susceptibility rates against both sets of isolates were meropenem and imipenem ($\geq 98.5\%$), and tigecycline ($\geq 94.6\%$). A high susceptibility rate was observed to amikacin among ESBL-negative isolates (95.1%); however, a lower rate of 83.4% was observed among ESBL-positive isolates. For cefepime, ceftazidime and aztreonam relatively high rates of susceptibility were observed among ESBL-negative isolates ($\geq 88.5\%$); however, a susceptibility rate of $< 10\%$ was seen among ESBL-positive isolates.

Analysis by region against levofloxacin-resistant *E. coli*

For the regional analysis of all years pooled (2012–2018), presented in Table 2, susceptibility rates to ceftazidime-avibactam were consistently high in all regions for both ESBL-positive (97.0% in Asia/South Pacific to 99.7% in Africa/Middle East and Latin America) and ESBL-negative (99.4% in Asia/South Pacific to 100% in Latin America) levofloxacin-resistant *E. coli*. High susceptibility rates were also observed in each region among ESBL-positive and ESBL-negative isolates for colistin (≥ 98.5%), imipenem (≥ 96.5%), meropenem (≥ 96.5%) and tigecycline (≥ 94.1%).

– Indicates no breakpoint for the agent						
ESBL, extended-spectrum β-lactamase; %I, percentage of isolates susceptible, increased exposure; MIC, minimum inhibitory concentration; MIC ₅₀ , MIC required to inhibit growth of 50% of isolates (mg/L); MIC ₉₀ , MIC required to inhibit growth of 90% of isolates (mg/L); %R, percentage of isolates resistant; %S, percentage of isolates susceptible, standard dosing.						

Susceptibility rates to amikacin among ESBL-negative isolates were similar in all regions, from 94.4% in Africa/Middle East and Latin America to 96.5% in Europe. Among ESBL-positive isolates, susceptibility to amikacin was lower (79.9% in Europe to 89.8% in Asia/South Pacific). The susceptibility rates observed among ESBL-negative isolates to piperacillin-tazobactam were lowest in Europe (79.6%) and highest in

Latin America (84.9%). In comparison, rates of susceptibility to piperacillin-tazobactam among ESBL-positive isolates were lower in each region (for example, 61.3% in Europe).

High rates of susceptibility were observed among ESBL-negative levofloxacin-resistant *E. coli* for cefepime in all regions (between 91.1% and 93.3%) and for ceftazidime in three of the four regions (91.0–93.0%). A lower susceptibility rate to ceftazidime of 77.9% was observed among ESBL-negative isolates in Asia/South Pacific. Few ESBL-positive isolates from any region were susceptible to cefepime or ceftazidime ($\leq 6.3\%$). Susceptibility rates to ampicillin and amoxicillin-clavulanate were lower compared with all other agents in each region for ESBL-negative isolates. Among each regional set of ESBL-positive isolates, susceptibility rates to ampicillin and amoxicillin-clavulanate were $\leq 41.6\%$.

In vitro activity data, by year, for ceftazidime-avibactam, colistin, meropenem, imipenem, and tigecycline against ESBL-positive and ESBL-negative isolates are presented in Supplemental Tables 1–5. Over time, ceftazidime-avibactam, colistin, meropenem and imipenem showed consistently high and stable rates of susceptibility ($\geq 96.7\%$) in Africa/Middle East, Europe and Latin America (Supplemental Tables 1–4). For ESBL-positive isolates collected in the Asia/South Pacific region, reduced susceptibility rates were observed in 2018 to ceftazidime-avibactam (91.8%, Supplemental Table 1), and to imipenem (90.4%) and meropenem (91.1%) (Supplemental Tables 3 and 4) when compared with each of the preceding years. Susceptibility to tigecycline was $> 92.6\%$ between 2013 and 2018; rates of susceptibility were lower in 2012.

Regional trend tests against levofloxacin-resistant *E. coli* over time

Figure 1 shows the proportion of levofloxacin-resistant *E. coli* isolates identified as ESBL-positive from each region and by year. Any changes in the rates of ESBL-positive, levofloxacin-resistant *E. coli* over time were not statistically significant in Africa/Middle East and Latin America. For isolates from Europe and Asia/Pacific there was a statistically significant increase in the rates of ESBL-positive isolates over time ($p = 0.0029$ and $p = 0.0001$, respectively) with rates in 2018 of 54.4% in Europe and 61.3% in Asia-Pacific.

Discussion

This analysis of levofloxacin-resistant *E. coli* isolates collected between 2012 and 2018 in four geographical regions as part of the ATLAS study, showed high susceptibility rates to ceftazidime-avibactam among ESBL-positive and ESBL-negative isolates. Data for 2012 to 2018 also showed high susceptibility rates to colistin, meropenem, imipenem, and tigecycline, rates that were common to all regions and both ESBL-positive and ESBL-negative isolates. Susceptibility to cefepime, ceftazidime and aztreonam was also high against ESBL-negative isolates; however, susceptibility was reduced against ESBL-positive isolates with $< 10\%$ of isolates susceptible to cefepime, ceftazidime or aztreonam.

Year-by-year analysis for the Asia/South Pacific region revealed consistently high rates of susceptibility among fluoroquinolone-resistant *E. coli* to ceftazidime-avibactam, colistin, meropenem, imipenem and tigecycline between 2012 and 2017; however, susceptibility rates to meropenem, imipenem and

ceftazidime-avibactam among ESBL-positive isolates in 2018 were lower compared with the previous years (91.1%, 90.4% and 91.8%, respectively). These decreases in the rates of susceptibility to meropenem, imipenem and ceftazidime-avibactam warrant further monitoring. The Asia/South Pacific region is considered a key area for the emergence and spread of antimicrobial resistance [22], and lower rates of antimicrobial susceptibility have been reported for the region in other studies. For example, lower susceptibility rates among *E. coli* isolates in Asia have been reported recently as part of the Study for Monitoring Antimicrobial Resistance Trends (SMART). The rate of susceptibility to ertapenem against *E. coli* was lower in Asia ($\geq 92.1\%$) than all six other regions ($\geq 96.1\%$) for each year of the analysis (2012–2016) [23].

There have been reports of *E. coli* strains that are resistant to fluoroquinolones becoming more widespread during recent years [24]. Of particular concern has been the global spread of *E. coli* strain ST131, which is characterised by co-resistance to fluoroquinolones and other agents [8–10, 25, 26]. It is unlikely that this strain could be the cause of the lowered susceptibility we observed to ceftazidime-avibactam and the two carbapenems in the Asia/South Pacific region in 2018. Among *E. coli* ST131 the rate of resistance to carbapenems is considered to be low, and a recent study of the *in vitro* activity of ceftazidime-avibactam and comparators against *E. coli* ST131 isolates in the USA reported no resistance to ceftazidime-avibactam or meropenem [27]. A more likely explanation could be the appearance of metallo- β -lactamases (MBLs) in isolates collected in the Asia/South Pacific region during 2018. Whilst MBL-positive isolates are frequently reported among *Klebsiella pneumoniae*, they are also disseminated to a lesser extent among *E. coli*, and so their inclusion among a population of levofloxacin-resistant isolates would not be surprising [28].

Antimicrobial stewardship action plans can lead to a reduction in fluoroquinolone use [29], and there is some evidence this can result in a reduction in antimicrobial resistance [30]. In addition, effective treatment of infections caused by *E. coli* needs to be guided by an awareness of local antimicrobial resistance data and local susceptibility testing results that allow selection of an appropriate agent [31]. The continuation of surveillance of regional resistance trends is of paramount importance, particularly in regions where there is a paucity of surveillance data or where resistance is considered to be increasing.

ATLAS is intended for antimicrobial surveillance and is not designed as an epidemiological study. Therefore, the observations regarding the frequency of ESBLs need to be treated with caution, and additionally it must be remembered that the isolates included in this analysis are all levofloxacin-resistant, predisposing the collection to higher rates of ESBL-positive isolate than might be identified in other clinical collections of *E. coli*. Additionally, centres that have participated in ATLAS have not been required to do so in each year, so the analysis of longitudinal data could be influenced by changes in the distribution of isolates over time. In our analyses, data were not available for India or China, and so our findings cannot reasonably be applied to these individual countries, and the same applies for North America. Whilst centres from many countries have participated in this analysis, their geographical distribution has focussed around four main regions and so the observations that we present may not be fully representative of global susceptibility trends.

Conclusions

In conclusion, we report that the in vitro susceptibility of ceftazidime-avibactam among levofloxacin-resistant *E. coli* isolates, including ESBL-positive isolates, collected from four geographical regions between 2012 and 2018 was consistently high ($\geq 97.0\%$). Susceptibility to the comparator agents colistin, tigecycline, imipenem and meropenem was also high ($\geq 94.1\%$), whilst susceptibility to other agents on the panel was lower, particularly among ESBL-positive isolates. A modest reduction in susceptibility to imipenem, meropenem, and ceftazidime-avibactam in the Asia/South Pacific region in 2018 warrants continued antimicrobial surveillance. The identification of global and regional trends of antimicrobial resistance can help to guide appropriate treatment of infectious disease where *E. coli* is the suspected or confirmed causative organism.
