# Abstract

The gut produces toxins that contribute to the cardiovascular complications of chronic kidney disease. Canagliflozin, a sodium glucose cotransporter (SGLT) 2 inhibitor that is used as an anti-diabetic drug, has a weak inhibitory effect against SGLT1 and may affect the gut glucose concentration and environment. Here, we determined the effect of canagliflozin on the gut microbiota and the serum gut-derived uremic toxin concentrations in 5/6<sup>th</sup> nephrectomized (Nx) rats. Canagliflozin increased the colonic glucose concentration and restored the number of *Lactobacillus* bacteria, which was low in Nx rats. In addition, the expression of tight junction proteins in the ascending colon was low in Nx rats, and this was partially restored by canagliflozin. Furthermore, the serum concentrations of gut-derived uremic toxins were significantly increased by Nx and reduced by canagliflozin. Finally, the wall of the thoracic aorta was thicker and there was more cardiac interstitial fibrosis in Nx rats, and these defects were ameliorated by canagliflozin. The increases in colonic glucose concentration, *Lactobacillus* numbers, and tight junction protein expression; and the decreases in serum uremic toxin concentrations and cardiac interstitial fibrosis may have been caused by the inhibition of SGLT1 by canagliflozin because similar effects were not identified in tofogliflozin-treated rats.

## Introduction

The number of patients with chronic kidney disease (CKD) is increasing alongside the aging of the population and the increases in the prevalences of hypertension and diabetes. However, conventional therapies for CKD, such as blood pressure control and a low-protein diet, are not sufficient to stop the progression of CKD. Recently, there has been growing interest in the gut as a therapeutic target of CKD. Colonic bacteria are the principal source of several uremic toxins and that the composition of the intestinal microbiome differs in CKD<sup>2-4</sup>. In particular, larger numbers of intestinal bacteria that express urease and uricase and produce indole or p-cresol have been demonstrated in patients with end-stage renal disease (ESRD)<sup>5</sup>. Because most of the colon microbiota-derived uremic toxins are nephrotoxic, as well as having cardiotoxic effects, the dysbiosis that characterizes CKD might contribute to the progression of renal failure and the incidence of cardiovascular events<sup>6-9</sup>.

Previous study showed that there is a larger population of *Bacteroides* and a smaller population of *Lactobacillus* species in 5/6<sup>th</sup> nephrectomized (Nx) rats, which leads to dysfunction of their intestinal epithelial barrier<sup>10-12</sup>. This can be explained by the ability of *Lactobacillus* species to maintain the expression of tight junction (TJ) proteins<sup>13</sup>, which limits the accumulation of uremic toxins in the serum of patients or animals with CKD. Therefore, a therapeutic strategy that corrects this dysbiosis may be clinically useful, and several kinds of prebiotic and probiotic therapies have been tested for renoprotective or cardioprotective effects in animal models of and patients with CKD<sup>14-16</sup>.

In the present study, we aimed to determine whether the anti-diabetic drug canagliflozin, which is a sodium glucose cotransporter (SGLT) 2 inhibitor, has prebiotic effects. SGLT2 inhibitors reduce the blood glucose concentration by inhibiting glucose reabsorption in kidney tubules and promoting glucose

excretion in the urine. There are six isoforms of SGLT, and SGLT2 is predominantly expressed in the renal proximal tubule, whereas SGLT1 is expressed in small intestinal epithelial cells, where it plays a major role in intestinal glucose absorption. Canagliflozin differs from other SGLT2 inhibitors in that it weakly inhibits SGLT1, and it therefore might affect the gut environment. An *in vitro* comparison of the six different clinically available SGLT2 inhibitors in SGLT-overexpressing cells showed that canagliflozin had a 290-fold selectivity for SGLT2 vs. SGLT1 (the lowest selectivity), whereas that of tofogliflozin was 2900 (the highest selectivity)<sup>17</sup>. In another study, the inhibition constants (K<sub>i</sub>) for SGLT1 and SGLT2 were 770.5 and 4.0 nM, respectively<sup>18</sup>. The K<sub>i</sub> value for SGLT1 suggests that canagliflozin inhibits SGLT1 in the small intestine from the luminal side. Therefore, we hypothesized that canagliflozin might affect the dysbiosis of animals with CKD, and thereby influence renal or cardiovascular function. In the present study, we aimed to determine the effects of canagliflozin on the gut microbiota and uremia of non-diabetic rats with CKD, and to determine whether it has a protective effect on the cardiovascular system.

## Results

**Effects of canagliflozin on rat physiology.** The Nx rats lost weight but there was no significant difference in body mass between Nx rats and Nx rats treated with canagliflozin (Nx + C group) (Table 1). There were no significant differences in daily food intake among sham-operated, Nx, and Nx + C rats (Table 1). The Nx rats developed hypertension, unlike the sham-operated rats, but there was no difference in blood pressure between the Nx rats and Nx + C rats (Table 1). Treatment with canagliflozin significantly increased the volume of urine passed daily, compared with the Sham and the Nx rats (Table 1). These results suggest that canagliflozin induces osmotic diuresis by inhibiting SGLT2 in proximal tubular cells.

Table 1  
Effects of canagliflozin on physiological parameters. Data are presented as means ± SEMs. \**p* < 0.05, \*\**p* < 0.01 vs. the Sham group. ††*p* < 0.01 vs. the Nx group.

	Sham	Nx	Nx + C
Body weight (g)	364.7 ± 13.3	311.0 ± 42.8**	323.3 ± 18.8**
Food intake (g/day)	19.2 ± 1.9	17.1 ± 2.4	19.2 ± 0.3
Systolic blood pressure (mmHg)	168.8 ± 17.0	220.1 ± 32.8**	214.8 ± 22.8**
Daily urine volume (ml/day)	12.2 ± 3.1	29.5 ± 15.9*	37.4 ± 10.0**††

**Effects of canagliflozin on glucose tolerance, urine composition, and kidney function.** Oral glucose tolerance testing (OGTT) demonstrated no significant differences in glucose tolerance among the Sham, Nx, and Nx + C groups (Fig. 1a). Nx rats developed substantial proteinuria, which was more pronounced in canagliflozin-treated rats (Fig. 1b). Canagliflozin significantly increased daily urinary glucose excretion, compared with the Sham and Nx groups (Fig. 1c). Both the blood urea nitrogen (BUN) and serum creatinine concentrations were significantly higher in Nx than Sham rats, and canagliflozin did not affect these parameters (Fig. 1d and e, respectively). Renal histological analysis revealed that Nx rats had

substantial glomerulosclerosis, which was not affected by canagliflozin treatment (Fig. 1f, upper panel). In addition, the glomerulosclerotic index was high in the Nx rats, and this was not improved by canagliflozin administration (Fig. 1f, lower panel). Similarly, Nx rats showed substantial interstitial fibrosis (blue staining) that was not affected by canagliflozin treatment (Fig. 1g). These data indicate that canagliflozin does not ameliorate the glomerulosclerosis or interstitial fibrosis that characterize Nx rats.

**Effect of canagliflozin on the gut microbiota and intestinal barrier.** We next determined the effect of canagliflozin on the gut environment of Nx rats. The quantity of glucose per 10 cm of colon was higher in the Nx + C group than in the Sham or Nx groups (Fig. 2a), which confirms that canagliflozin inhibits SGLT1 in Nx rat colon and implies that canagliflozin might alter the composition of the microbiota in Nx rats. Quantitative analysis of the microbiota showed that *Bacteroides* species were more abundant in Nx rats and that canagliflozin had no effect on this difference (Fig. 2b). Conversely, *Lactobacillus* species were significantly less abundant in Nx rats, and this phenotype was reversed by canagliflozin treatment (Fig. 2c). In our previous study<sup>13</sup>, the presence of *Lactobacillus* restored the CKD-related defect in the intestinal barrier by restoring the expression of TJ proteins. Immunoblotting analysis showed reductions in expression of both the transcellular TJ proteins claudin-1 and occludin and the cytosolic scaffold protein zonula occludens (ZO)-1 in Nx rats vs. Sham rats, and that canagliflozin restored the expression of each of these in the colons of Nx rats (Fig. 2d).

**Effects of canagliflozin on the serum concentration of uremic toxins and the cardiovascular system.**

Because canagliflozin affects the expression of colonic TJ proteins, we predicted that it would also affect the serum concentration of gut-derived uremic toxins. The serum concentrations of uremic toxins such as indoxyl sulfate (IS), hippuric acid (HA), and indole acetic acid (IAA) were significantly increased by 5/6th nephrectomy (Fig. 3a), as was that of P-cresyl sulfate (PCS), but this effect did not achieve statistical significance (Fig. 3a). Although canagliflozin had no effects on the serum concentrations of PCS or IAA, it significantly reduced those of IS and HA (Fig. 3a). IS has been shown to promote aortic wall thickening and calcification and to aggravate cardiac fibrosis<sup>19-22</sup>. Therefore, we assessed the aortic wall thickening and cardiac fibrosis in each group. The Nx rats had significantly thicker thoracic aortic walls than the Sham rats (Fig. 3b). In addition, the extent of intestinal fibrosis, assessed using Picosirius red staining, was significantly greater in the Nx group than in the Sham group (Fig. 3c). As shown in Fig. 3b and c, canagliflozin ameliorated both the aortic wall thickening and cardiac interstitial fibrosis. Moreover, the increases in cardiac *Tgfb1* and *Ctgf* mRNA expression in Nx rats were significantly ameliorated by canagliflozin treatment (Fig. 3d).

**Effects of tofogliflozin on the glucose tolerance, urine composition, gut microbiota, intestinal barrier, and serum concentrations of uremic toxins of the rats.**

OGTT demonstrated no significant differences in glucose tolerance among the Sham, Nx, and tofogliflozin-treated Nx (Nx + T) groups (Fig. 4a). Tofogliflozin treatment increased urinary glucose excretion to a similar extent to canagliflozin treatment (Fig. 4b), which implies that it similarly inhibited SGLT2 in the kidney. However, because tofogliflozin has very little binding affinity for SGLT1 it failed to increase the amount of glucose in the colon compared

with the Sham and Nx groups, whereas canagliflozin treatment increased the amount of glucose in the colon vs. the Sham, Nx, and Nx + T groups (Fig. 4c). RT-PCR for *Lactobacillus* species revealed that there was no significant difference in the abundance of these bacteria between the Nx + T group and the Nx group, but they were more abundant in the Nx + C group than in either the Nx group or the Nx + T group (Fig. 4d). Immunoblotting analysis of the rat colons showed that the expression of the TJ proteins claudin-1, occludin, and ZO-1 was lower in the Nx group. The reductions in the expression of claudin-1 and occludin appeared to be ameliorated by treatment with tofogliflozin, but these effects did not achieve statistical significance (Fig. 4e). Finally, the higher serum concentrations of IS and HA in the Nx rats were not affected by treatment with tofogliflozin (Fig. 4f).

**Comparison of the effects of tofogliflozin and canagliflozin on the cardiovascular system.** As described above, canagliflozin ameliorated the cardiac interstitial fibrosis that was caused by Nx. However, tofogliflozin did not have this effect (Fig. 5a). Similarly, the high *Tgfb1* and *Ctgf* mRNA expression in the hearts of the Nx rats was significantly reduced by canagliflozin, but not by tofogliflozin (Fig. 5b).

## Discussion

In the present study, we have demonstrated that canagliflozin increases the glucose content of the colon and increases the abundance of *Lactobacillus* species in the microbiota of a non-diabetic rat model of CKD. This likely explains the restoration of the intestinal barrier function by canagliflozin and the reduction in the serum concentrations of IS and HA. Although canagliflozin did not affect the renal function of the rats, it ameliorated their arterial wall thickening and cardiac fibrosis. These protective effects were presumably the result of the lower serum uremic toxin concentrations. In addition, another SGLT2 inhibitor, tofogliflozin, which has a minimal effect on SGLT1, did not significantly affect the gut microbiota, expression of gut TJs, serum gut-derived uremic toxin concentrations, or the degree of cardiac fibrosis in the Nx rats. We conclude that the effects of canagliflozin on the gut microbiota, uremic toxins, and heart are independent of its glucose-lowering effects and are related to its inhibitory effects on gut SGLT1.

Canagliflozin differs from other SGLT2 inhibitors in that it weakly inhibits SGLT1 and thereby reduces postprandial intestinal glucose absorption<sup>23</sup>. We hypothesized that this SGLT1 inhibition might affect the uremic state. A previous study showed that phlorizin, a natural polyphenol and dietary constituent that is known to potently inhibit intestinal SGLT1, modifies the gut microbial community structure of diabetic mice<sup>24</sup>. Specifically, it increases the abundances of *Akkermansia muciniphila* and *Prevotella*, and this effect may be mediated through inhibition of intestinal SGLT1<sup>24</sup>. Consistent with these reports, the present study demonstrated that canagliflozin but not tofogliflozin largely restores the correct proportion of *Lactobacillus* in the microbiota of CKD rats, probably through its inhibition of SGLT1. The mechanism whereby intestinal SGLT1 inhibition leads to *Lactobacillus* growth in the colon is not completely understood. However, it is thought that SGLT1 inhibition causes glucose malabsorption in the small intestine and a consequent increase in glucose delivery to the colon, which was also suggested in the present study. Because *Lactobacillus* uses glucose as a substrate for fermentation, it is likely that the

higher colonic glucose concentration would stimulate the growth of *Lactobacillus*. Some previous studies have already shown that *Lactobacillus* species multiply in glucose-rich conditions<sup>25,26</sup>. Furthermore, studies of prebiotics have shown that an increase in the supply of substrate leads to an increase in the population of the intestinal bacteria which metabolize that substrate<sup>27-29</sup>. Taking these findings together, it can be surmised that an increase in glucose delivery to the colon stimulates an increase in the abundance of *Lactobacillus* species, which has various beneficial effects.

*Lactobacillus* is a well-known probiotic that is capable of reducing the serum concentrations of uremic toxins, such as PCS and IS, in patients with CKD<sup>30-32</sup>. We have also demonstrated that a substantial *Lactobacillus* population is associated with intactness of the intestinal barrier in CKD rats, which involves the maintenance of TJ protein expression and low serum concentrations of PCS and IS<sup>13</sup>. The present finding that canagliflozin, but not tofogliflozin, treatment is associated with restoration of intestinal barrier function in the same way to that shown in our previous study lead us to surmise that the maintenance of TJ expression induced by canagliflozin is the result of its effect to promote the growth of *Lactobacillus* species. However, the effect of canagliflozin administration differs from that of *Lactobacillus* administration, because it did not cause a reduction in the serum concentration of PCS. This disparity might relate to differences in the biosynthetic pathways for IS and PCS. The IS precursor indole is directly absorbed through TJs, whereas the PCS precursor p-cresol is conjugated at the colonic epithelium before being absorbed through TJs<sup>4,33,34</sup>. It is possible that the high concentration of glucose in the intestine that is induced by canagliflozin treatment, but that is not induced by *Lactobacillus* prebiotic treatment, might affect intestinal epithelial function. This might modify the absorption of p-cresol, and because HA is absorbed through TJs in a similar manner to IS<sup>35</sup>, the serum concentration of HA was also affected by canagliflozin administration. IAA differs from the other three uremic toxins in that it is generated in part outside the gut<sup>36,37</sup>, which may explain the lack of effect of canagliflozin on serum IAA concentration.

It is well known that IS stimulates the progression of both tubulointerstitial fibrosis and glomerular sclerosis in CKD by inducing reactive oxygen species (ROS) production<sup>38,39</sup>. However, in the present study, canagliflozin reduced the serum IS concentration but failed to ameliorate the renal tubulointerstitial fibrosis or glomerular sclerosis. The progression of CKD is multifactorial, involving hyperactivity of the intrarenal renin-angiotensin-aldosterone system<sup>40</sup>, tissue hypoxia<sup>41,42</sup>, and high serum concentrations of uremic toxins<sup>43-45</sup>. Therefore, it is perhaps not surprising that a reduction in the serum IS concentration alone did not prevent the progression of CKD in the present study. However, canagliflozin ameliorated both the aortic wall thickening and cardiac interstitial fibrosis of the Nx rats. IS has been shown to induce oxidative stress in cardiomyocytes and to aggravate cardiac fibrosis<sup>19,20,45,46</sup>, and it has also been previously shown that CKD-induced cardiac fibrosis can be ameliorated by a reduction in the circulating concentration of IS<sup>19,47</sup>. In the present study, the high cardiac expression of *Tgfb1* and *Ctgf* in the Nx rats was ameliorated by treatment with canagliflozin, which suggests that canagliflozin ameliorates cardiac fibrosis by reducing the serum IS concentration and inhibiting the fibrogenic ROS-nuclear factor- $\kappa$ B-transforming growth factor  $\beta$  pathway. In addition, IS has been shown to induce oxidative stress in

endothelial cells and promote aortic wall thickening<sup>20–22</sup> Therefore, we believe that canagliflozin ameliorates the aortic wall thickening of the Nx rats by reducing their serum IS concentration.

In the present study, the cardiac fibrosis of the Nx rats was reduced by canagliflozin treatment but not by tofogliflozin treatment. This implies that the inhibition of SGLT1 may be the mechanism whereby canagliflozin has an anti-atherosclerotic effect in this non-diabetic model of CKD. There have been few reports of the effects of SGLT2 inhibitors in animal models of or patients with non-diabetic CKD. One previous study showed that the SGLT2 inhibitor dapagliflozin does not prevent proteinuria or a decline in GFR in non-diabetic Nx rats<sup>48</sup>, which is consistent with the results of the present study. Recently, canagliflozin was also shown to alter the gut microbial composition and reduce the plasma concentrations of PCS and IS in mice with adenine-induced CKD<sup>49</sup>. In their paper, the authors hypothesized that the inhibition of SGLT1 by canagliflozin affects the intestinal environment and reduces the accumulation of uremic toxins. However, they did not study the cardiovascular effects of the drug, and so the present study is the first to show beneficial effects of a SGLT2 inhibitor on cardiovascular complications in a non-diabetic model of CKD. We conclude that canagliflozin may improve the long-term prognosis of patients with CKD by ameliorating their cardiac fibrosis and atherosclerosis.

In conclusion, we have shown that the SGLT2 inhibitor canagliflozin protects the cardiovascular system of non-diabetic rats with CKD through its inhibition of SGLT1. The mechanism likely involves a reduction in the serum concentrations of gut-derived uremic toxins, secondary to an increase in the abundance of *Lactobacillus*. These findings suggest a novel therapeutic strategy for the cardiovascular complications of patients with CKD.

## Methods

**Animal care and experiments.** Six-week-old, male, spontaneously hypertensive rats (Charles River, Wilmington, MA, USA) were randomly assigned to three experimental groups: a sham-operated group, an Nx group, and an Nx + C group, which was administered 0.024% canagliflozin in standard chow (Mitsubishi Tanabe Pharma Corporation, Osaka, Japan). We also conducted a study using another SGLT2 inhibitor, tofogliflozin. In this study, 6-week-old, male rats were assigned to the same three groups, plus a fourth Nx + T group, which was administered 0.015% tofogliflozin in standard chow (Kowa Pharmaceutical Co. Ltd., Montgomery, AL, USA). The doses of canagliflozin and tofogliflozin used were based on a previous study which showed that these were the doses required to significantly increase urinary glucose excretion and reduce blood glucose concentration in diabetic animals<sup>50–52</sup>. We also confirmed that the administration of each drug generated a similar plasma glucose curve during OGTT (Fig. 1a and 4a). Nephrectomy was performed as previously described<sup>53</sup>. At 17 weeks of age, OGTT was performed by orally administering 2 g/kg of glucose solution after overnight fasting, then measuring the blood glucose concentrations of the rats 0, 30, 60, and 120 min later using a blood glucose meter (One Touch UltraVue, Johnson and Johnson, New Brunswick, NJ, USA). On the day following OGTT, the rats were housed in individual metabolic cages for 24 hours to determine their daily urine output and food

intake. The following week, their body masses and systolic blood pressures were measured, then they were terminally anesthetized. At 30 weeks of age, the mice were anesthetised by thiopental sodium injection (30 mg/kg) and isoflurane 3% inhalation and exsanguinated through a cervical artery incision under anaesthesia. The colon of each was removed to measure their glucose contents, and samples were snap-frozen in liquid nitrogen for subsequent measurements. The kidneys, thoracic aorta, and the remaining half of the heart were sliced transversely and fixed in 10% formalin solution for tissue sectioning. The animal studies were performed in accordance with the guidelines and regulations for animal experimentation of, and were approved by, the Keio University Animal Care and Use Committee (approval number KO 15069). And this study was carried out in compliance with the ARRIVE guidelines (<http://www.nc3rs.org.uk/page.asp?id=1357>). Every effort was made to minimize the suffering of the rats.

**Measurement of the intestinal glucose content.** Intestinal glucose content was measured as previously described<sup>54</sup>. Briefly, the contents of the colon were collected using 5 ml ice-cold saline and the volume was measured. The carbohydrates in the collected sample were hydrolyzed by boiling in H<sub>2</sub>SO<sub>4</sub>, then the mixture was neutralized using NaOH. The glucose content was then measured using a kit (LabAssay Glucose, Fujifilm Wako Pure Chemical Industries, Osaka, Japan).

**Physiological and biochemical analyses.** Systolic blood pressure was measured using the tail-cuff method (Model MK-1030, Muromachi Kikai, Tokyo, Japan). Urinary protein excretion was measured using the pyrogallol red method and urinary glucose excretion using the hexokinase method. The serum concentration of creatinine was measured using the creatininase-creatinase-Sarcosine oxidase-Peroxidase method. BUN was measured using the urease method. The serum concentrations of IS, PCS, HA, and IAA were measured by high-performance liquid chromatography as previously described<sup>55</sup>.

**Histological examination.** Kidney sections were stained using periodic acid-Schiff to assess glomerular sclerosis and using Masson's trichrome to assess interstitial fibrosis. Glomerulosclerosis was evaluated by counting sclerotic glomeruli and calculating the glomerulosclerotic index<sup>56,57</sup>. The proportion of the area of each kidney section that was fibrotic was measured using ImageJ software (NIH, Bethesda, MD, USA). The thickness of the aortic wall was determined on hematoxylin and eosin-stained sections by obtaining digital images (Upright optical microscope BX53, Olympus, Tokyo, Japan) and measuring the thickness in five different places per using Image J. The mean value was considered to be representative for each rat. The myocardium was stained using Picrosirius red and the proportion of the area on each section that was stained red was measured using Image J and used as a measure of the degree of fibrosis.

**Analysis of the gut microbiota.** Fecal samples were suspended in 4 M guanidium thiocyanate, 100 mM Tris-HCl (pH 9.0), and 40 mM EDTA, and then homogenized using zirconia beads (5 m/s, 5 min) and a FastPrep FP100A instrument (MP Biomedicals, Santa Ana, CA, USA). DNA was extracted from the homogenates using a GC series Genomic DNA Whole Blood kit (Precision System Science, Chiba, Japan). After adjusting the final concentration of the extracted DNA to 10 ng/μl, fecal 16S rDNA was amplified by

PCR. The primers used were 6-FAM-labeled 516f (5'-TGCCAGCAGCCGCGGTA-3') and 1510r (5'-GGTTACCTTGTACGACTT-3'). The amplified DNA was verified by electrophoresis and purified using a MultiScreen FB filter plate (Millipore, Bedford, MA, USA). The abundance of specific bacterial groups in the rat fecal samples was measured by real-time quantitative PCR using the 7500 Fast Real-time PCR System (Applied Biosystems, Foster City, CA, USA). The specific primers for *Lactobacillus* and *Bacteroides* species are shown in Table 2. The results obtained using the specific primers were normalized to those obtained using the universal primers.

Table 2  
Primers used for the quantification of bacterial genera.

<b>Bacteria</b>	<b>Forward</b>	<b>Reverse</b>
<i>Lactobacillus</i>	AGCAGTAGGGAATCTTCCA	CACCGCTACACATGGAG
<i>Bacteroides</i>	GAAGGTCCCCACATTG	CAATCGGAGTTCTTCGTG
Universal primers	TCCTACGGGAGGCAGCAGT	GACTACCAGGGTATCTAATCCTGTT

**Western blot analysis.** Frozen ascending colon samples were homogenized in cold RIPA Lysis buffer (Santa Cruz Biotechnology, Dallas, TX, USA) containing protease and phosphatase inhibitors, and the homogenates were centrifuged at  $12,000 \times g$  at  $4^{\circ}\text{C}$  for 15 min. The supernatants were collected and the protein concentration of each was determined using a DC protein assay kit (Bio-Rad Laboratories, Inc. Hercules, CA, USA). Equivalent amounts of protein (50  $\mu\text{g}$ ) were loaded and electrophoresed on 7.5%, 10%, or 12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis gels and transferred to polyvinylidene difluoride membranes. The resulting blots were incubated with primary antibodies against rat ZO-1, occludin, claudin-1 (Invitrogen, Carlsbad, CA, USA), or  $\beta$ -actin (Cell Signaling Technology, Danvers, MA, USA). After washing, the blots were incubated with secondary antibody (horseradish peroxidase-linked anti-rabbit IgG; GE Healthcare, Amersham, UK) and the protein-antibody complexes were detected using an ECL detection kit (Amersham Biosciences, Uppsala, Sweden), according to the manufacturer's recommended protocol.

**Real-time reverse transcriptase-polymerase chain reaction.** RNA was extracted from frozen cardiac tissue using an RNeasy Mini Kit (Qiagen, Hilden, Germany). Equal amounts (1  $\mu\text{g}$ ) of RNA from each sample were reverse transcribed to cDNA using a Prime Script RT reagent kit with gDNA Eraser (Takara, Ohtsu, Japan). Real-time RT-PCR was then performed using the 7500 Fast Real Time PCR System (Applied Biosystems). The primers used are shown in Table 3. Glyceraldehyde 3-phosphate dehydrogenase was used as the reference protein.

Table 3  
Primers used for real-time PCR.

Gene	Forward	Reverse
TGF $\beta$ (rat)	CATTGCTGTCCCGTGCAGA	AGGTAACGCCAGGAATTGTTGCTA
CTGF (rat)	CATGGTCAGGCCCTGTGAA	CACAGAACTTAGCCCGGTAGGTC
GAPDH (rat)	GTTACCAGGGCTGCCTCTC	GGGTTTCCCGTTGATGACC

**Statistical analysis.** Data are presented as means  $\pm$  SEMs and were analyzed using one-way analysis of variance, followed by Bonferroni's *post-hoc* test.  $P < 0.05$  was considered to represent statistical significance.

## Declarations

### Acknowledgements

We thank Mark Cleasby, PhD, from Edanz Group (<https://jp.edanz.com/ac>) for editing a draft of this manuscript.

### Author contributions statement

A.M. and A.Y. performed the experiments and drafted the manuscript. J.I., S.W., and H.I. designed the study, analyzed data, and drafted the manuscript. T.T., K.U., T.I., K.H., T.K., and H.T. coordinated the study.

## Figures

**Figure 1**

Effect of canagliflozin on biochemical parameters and kidney function. (a) Results of oral glucose tolerance testing. There were no significant differences in glucose tolerance among the three groups. (b) Effect of canagliflozin on 24-hr urinary protein excretion. Nephrectomized rats (Nx) developed substantial proteinuria. Canagliflozin further increased the magnitude of the proteinuria (Nx+C). (c) Effect of canagliflozin on 24-hr urinary glucose excretion. Canagliflozin significantly increased the 24-hr urinary

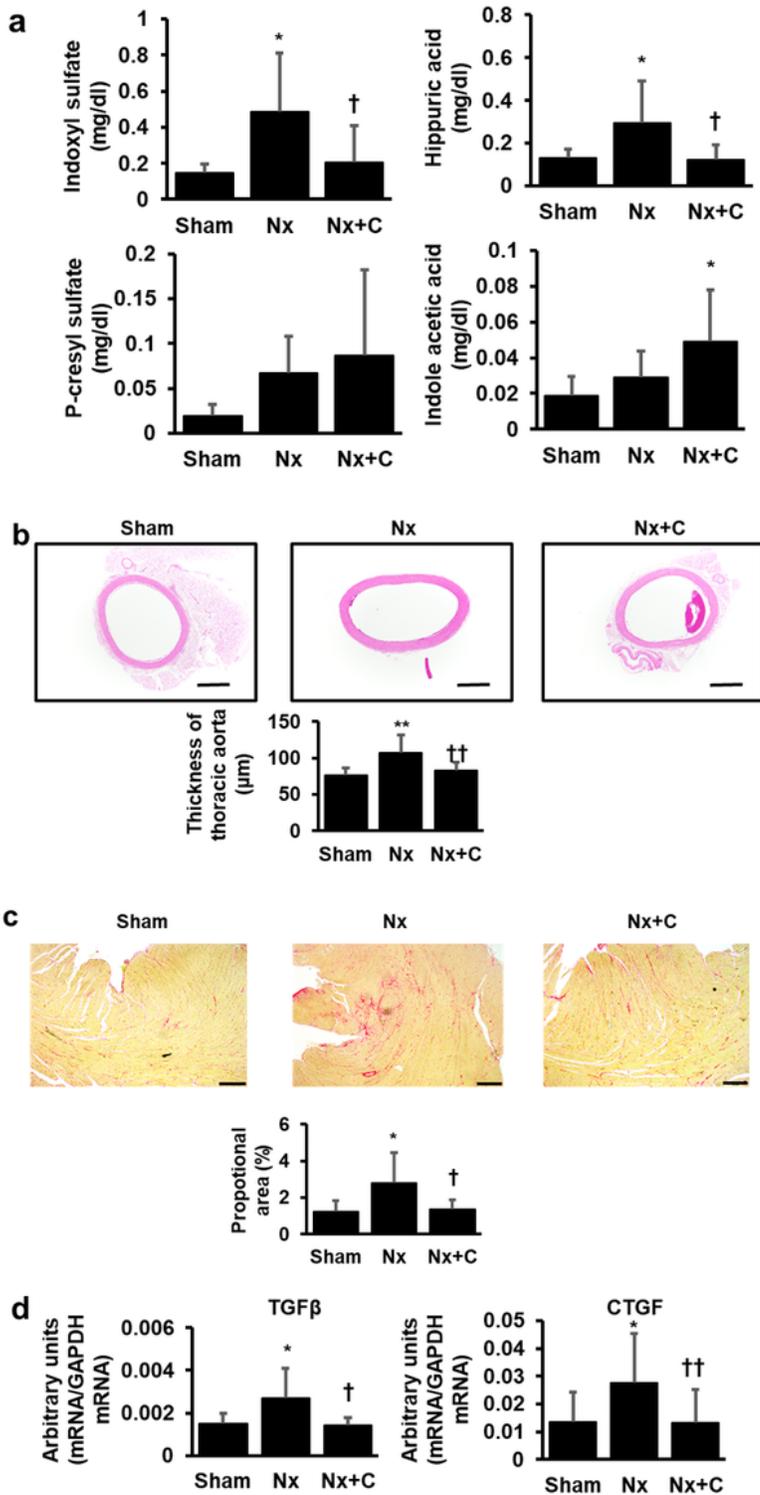

glucose excretion compared with the Sham and Nx groups. (d–e) Effect of canagliflozin on serum creatinine and BUN. Blood urea nitrogen (BUN) (c) and serum creatinine (d) concentrations were high in nephrectomized rats and canagliflozin failed to reduce these. (f) Representative images of glomeruli (upper panel) and quantitative analysis (lower panel) of periodic acid-Schiff-stained kidney sections. Compared with kidney sections from rats that had undergone sham surgery, those from Nx rats showed substantial glomerulosclerosis, and there was a similar level of glomerulosclerosis in canagliflozin-treated rats. Scale bars: 100  $\mu$ m. (g) Representative cortical tubulointerstitial images (upper panel) and quantitative analysis (lower panel) of Masson's trichrome-stained kidney sections. Compared with rats that had undergone sham surgery, kidney sections from Nx rats showed substantial interstitial fibrosis (blue), and there was a similar level of fibrosis in canagliflozin-treated rats. Scale bars: (f) 100  $\mu$ m and (g) 200  $\mu$ m. \* $p$ <0.05, \*\* $p$ <0.01 versus the Sham group; †† $p$ <0.05 versus the Nx group (n=12 per group).

**Figure 2**

Effect of canagliflozin on the gut microbiota and intestinal barrier. (a) Effect of canagliflozin on the colon glucose content. The amount of glucose in the colon was higher in the Nx+C group than in the Sham and Nx groups. (b) The abundance of *Bacteroides* in the colons of rats was quantified using RT-PCR.

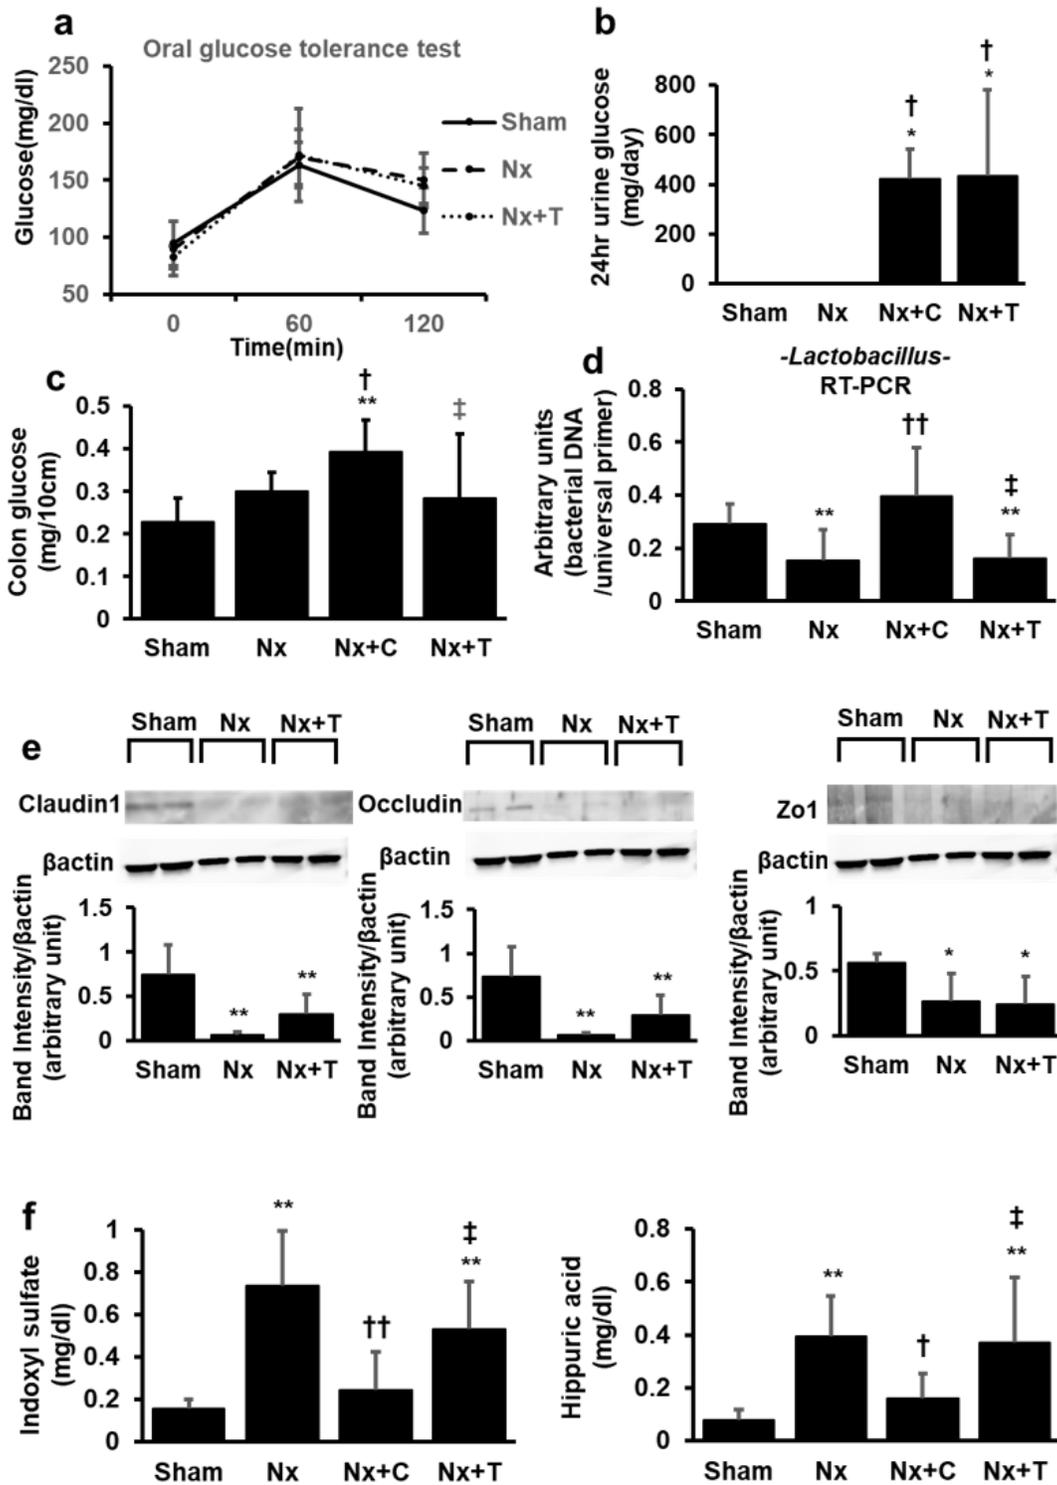

Bacteroides was significantly more abundant in Nx rats than Sham rats, but the abundance was not affected by canagliflozin administration. (c) The abundance of Lactobacillus in the colons of rats was quantified using RT-PCR. Lactobacillus was significantly less abundant in Nx rats, but significantly more abundant in canagliflozin-treated rats. (d) Expression of tight junction (TJ) proteins in the colon. Each upper subpanel shows an immunoblot of a TJ protein and each lower subpanel shows the densitometric analysis of its expression. The expression of claudin-1, occludin, and ZO-1 was lower in Nx rats than in Sham rats, but canagliflozin treatment significantly restored the expression of all of these. \* $p < 0.05$ , \*\* $p < 0.01$  versus the Sham group; † $p < 0.05$ , †† $p < 0.01$  versus the Nx group (n=12 per group).

**Figure 3**

Effects of canagliflozin on the serum concentrations of uremic toxins and the cardiovascular system. (a) Effect of canagliflozin on the serum concentrations of uremic toxins. The serum concentrations of indoxyl sulfate (IS) (upper panel) and hippuric acid (HA) (upper panel) were high in Nx rats and significantly lower in Nx+C rats. The serum concentration of p-cresyl sulfate (PCS) (lower panel) tended to be higher in Nx rats, but there was no difference between the Nx and Nx+C groups. The serum indoxyl

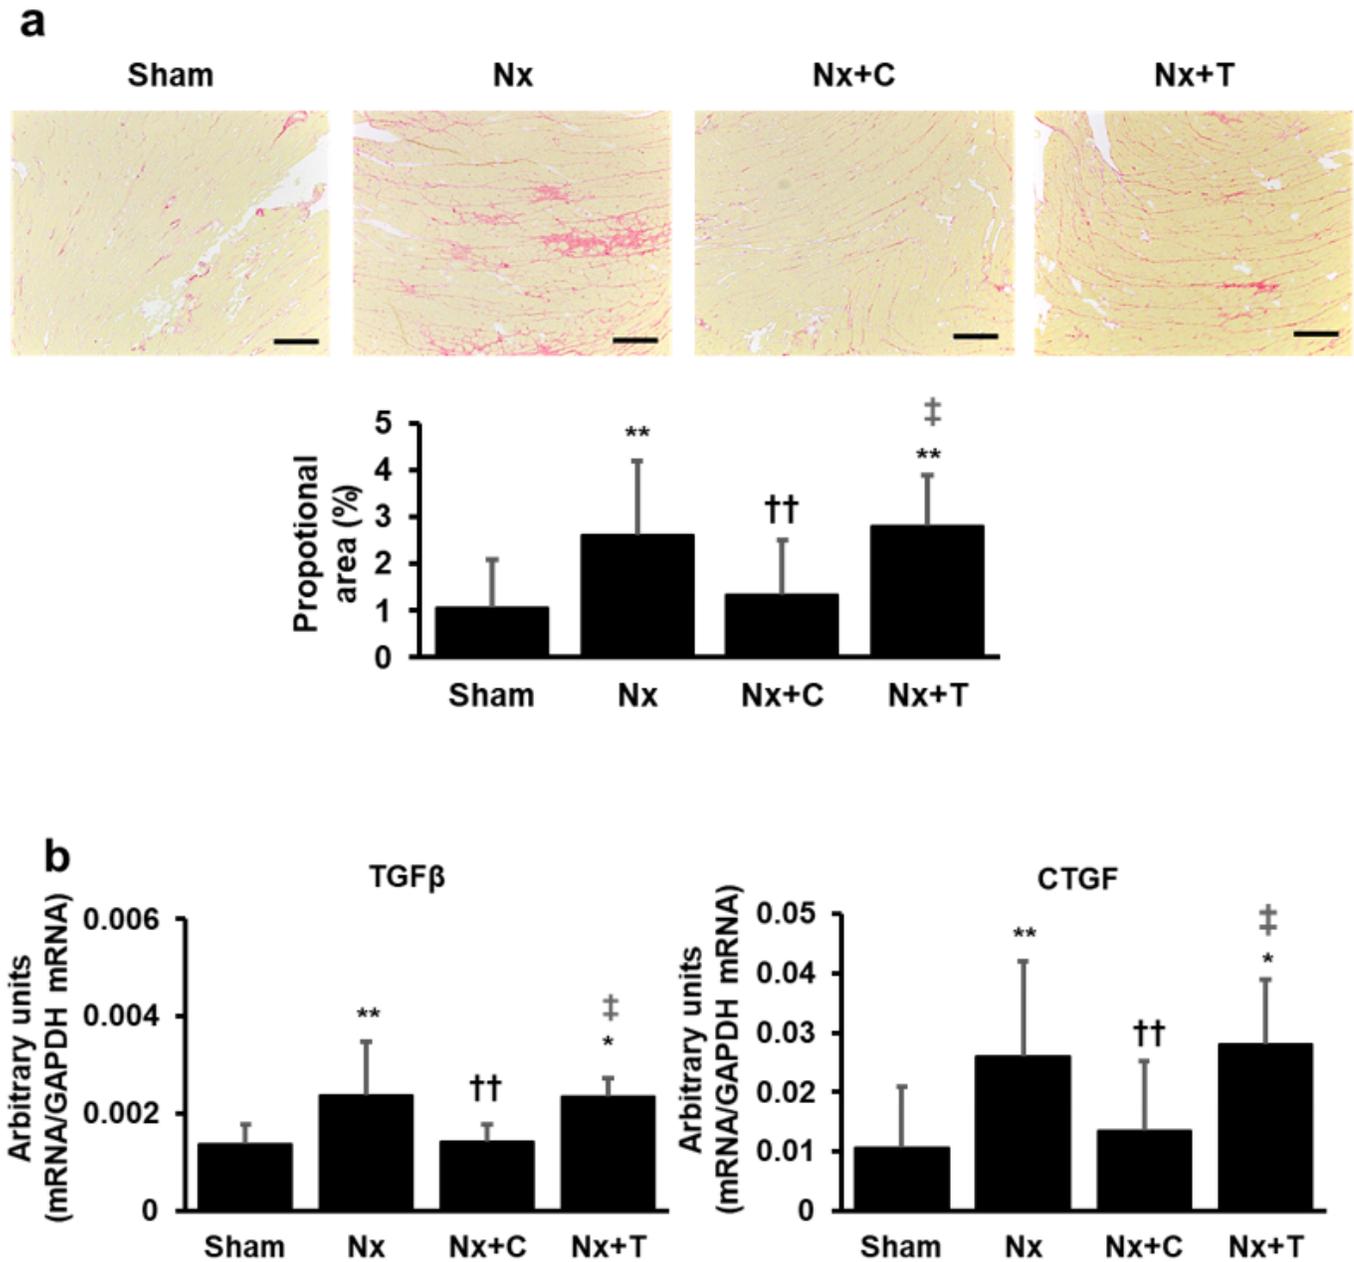

acetic acid (IAA) concentration (lower panel) was high in Nx rats, but there was no difference between the Nx and Nx+C groups. (b) Thickness of the thoracic aortic wall. Compared with rats that had undergone sham surgery, the thoracic aortic wall of Nx rats was thicker, and this was significantly ameliorated by canagliflozin administration. (c) Representative images of left ventricles stained using Picrosirius red (upper panel) and the proportion of the myocardium that was fibrotic (lower panel). The Nx group showed patchy fibrosis that was significantly more abundant than in the Sham group. However, treatment with canagliflozin significantly reduced this. (d) Cardiac Tgfb1 and Ctgf mRNA expression, measured using RT-PCR. The expression of both genes was significantly higher in Nx rats than Sham rats, but this was significantly reduced by canagliflozin treatment. Scale bars: (b,c) 500  $\mu$ m. \* $p$ <0.05, \*\* $p$ <0.01 versus the Sham group; † $p$ <0.05, †† $p$ <0.01 versus the Nx group (n=12 per group).

**Figure 4**

Comparisons of the effects of tofogliflozin and canagliflozin on the glucose tolerance, urine composition, microbiota, intestinal barrier, and serum concentrations of uremic toxins. (a) Results of oral glucose tolerance testing. There were no significant differences in glucose tolerance among the three groups. (b) Effect of tofogliflozin on 24-hr urinary glucose excretion. Tofogliflozin significantly increased 24-hr urinary glucose excretion versus the Sham and Nx groups. (c) Effect of tofogliflozin on colon glucose

content. There were no significant differences in the amount of glucose in the colons of Sham, Nx, and Nx rats treated with tofogliflozin (Nx+T), but the amount of glucose in the colon was higher in the canagliflozin-treated group. (d) The abundance of Lactobacillus in the colons of the rats was quantified using RT-PCR. Lactobacillus was significantly less abundant in the Nx group, but its normal abundance was restored by canagliflozin treatment. However, tofogliflozin administration had no effect. (e) Expression of the TJ proteins claudin-1, occludin, and ZO-1 in the colon. Each upper subpanel shows an immunoblot of a TJ protein and each lower subpanel shows the densitometric analysis of its expression. The expression of claudin-1, occludin, and ZO-1 was lower in the Nx rats than in the Sham rats. However, tofogliflozin failed to restore their expression. (f) Effect of tofogliflozin on the serum concentrations of uremic toxins. The concentrations of both indoxyl sulfate and hippuric acid were higher in Nx rats and tofogliflozin failed to ameliorate this defect. \* $p < 0.05$ , \*\* $p < 0.01$  versus the Sham group; † $p < 0.05$ , †† $p < 0.01$  versus the Nx group; ‡ $p < 0.05$  versus the Nx+C group (n=12 per group).

**Figure 5**

Effect of tofogliflozin on cardiac fibrosis. (a) Representative images of left ventricles stained using Picrosirius red (upper panel) and the proportions of the myocardium that were fibrotic (lower panel). The Nx group showed patchy fibrosis that was significantly worse than in the Sham group. Treatment with canagliflozin, but not tofogliflozin, significantly ameliorated this. Scale bars: 500  $\mu$ m. (b) Cardiac Tgfb1 (upper panel) and Ctgf (lower panel) mRNA expression, measured using RT-PCR. The expression of both was significantly higher in Nx rats. Unlike canagliflozin, tofogliflozin treatment failed to reduce the cardiac Tgfb1 and Ctgf mRNA expression. \* $p$ <0.05, \*\* $p$ <0.01 versus the Sham group; †† $p$ <0.01 versus the Nx group, ‡ $p$ <0.05 versus the Nx+C group ( $n$ =12 per group).
