**Version of Record:** A version of this preprint was published at BMC Women's Health on January 26th, 2022. See the published version at <https://doi.org/10.1186/s12905-022-01598-0>.

## Abstract

**Background:** Physical inactivity is a global health problem which is more prevalent among women. Among different age groups, middle-aged women are more vulnerable to physical inactivity as one of consequences of menopause. This study aimed to compare the effect of text messaging and that of mobile social networking on the improvement of physical activity and anthropometric indices of middle-aged women in Iran.

**Methods:** This was a randomized controlled trial in which 110 overweight or obese women who were physically inactive were recruited and allocated into two groups of text messaging (n=55) or mobile social networking (n=55). Women in both groups received information regarding the necessity, benefits, and barriers of physical activity and how to overcome these barriers for 12 weeks. The International Physical Activity Questionnaire (IPAQ), and a demographic questionnaire were used to collect data. Anthropometric indices including weight, height, waist circumference, hip circumference, waist/hip ratio, and body fat percentage were measured at baseline, as well as 4, 8, and 12 weeks after intervention. Data were analyzed using independent t-test, Chi-square, and repeated measure test.

**Results:** In the mobile social networking group, most women had moderate physical activity after 12 weeks ( $p < 0.05$ ). The mean physical activity and energy expenditure were significantly higher in the mobile social group than those in the text messaging. In the 12<sup>th</sup> week of intervention, there was a significant reduction in the weight and BMI of the participants in the mobile social networking group compared to the text messaging group ( $p < 0.05$ ). The waist and hip circumferences of women in the mobile social networking group reduced significantly after 12 weeks of intervention in comparison to the text messaging group ( $p = 0.001$ ). The two groups did not show any significant difference regarding waist/hip ratio.

While the body fat percentage was reduced in the mobile social networking group in the 4<sup>th</sup>, 8<sup>th</sup>, and 12<sup>th</sup> week of intervention, the differences between the two groups was not significant.

**Conclusion:** Both text messaging and mobile social networking were effective in promoting physical activity and reducing anthropometric indices except for waist/hip ratio and body fat percentages, but the effect of mobile social networking was more pronounced. Thus, mobile social networking is recommended for promoting physical activity among middle-aged women.

## Background

Physical inactivity is a health issue worldwide, and according to the World Health Organization, 23% of adults and 81% of adolescents lack sufficient physical activity (1). The prevalence of physical inactivity among the Iranian population is 30–70% according to gender and age group (2). Physical activity is reported to decline over age (3). Among different age groups, middle-aged women are more vulnerable to physical inactivity as one of the consequences of menopause. A Chinese study on 3,920 participants found that 63.9% of middle-aged women and 61.95% of their male counterparts were physically inactive (4). A study by Mohebi et al. showed that out of the 30,541 adults from 30 provinces in Iran, the prevalence of physical inactivity was 54.7% in a total population of whom 61.9% were adult women (5).

Physical inactivity increases the risk of chronic diseases such as cardiovascular disease, diabetes, obesity, cancer, and stroke (6). Physical inactivity is responsible for a significant number of the non-communicable disease outbreaks and caused 15.2% of all deaths in the US in 2015 (7). A large-scale study in Iran showed that important risk factors for morbidity and mortality among Iranian population aged 15–49 years were dietary risks, physical inactivity, high blood pressure, high body mass index, and smoking (8). In addition, low physical activity has been reported to have a strong association with dementia (9).

An empowerment-focused intervention that is aimed to promote physical activity can be particularly successful among women (10). A systematic review of 13 studies showed that SMS intervention has the potential to significantly promote physical activity (11). Yamashita et al. (12) in their study on 39 older female adults with age more than 65 years found that social networking plus monthly incentives could significantly promote the level of physical activity among these women. To the best of our knowledge, no study has yet compared the effect of text messaging and that of with social networks on promoting physical activity in middle-aged women. Litwin and Shaul (13) in their study on 17,104 elderly individuals in Israel found that those with

high social connectivity have vigorous physical activity. Also, a study by Nam et al (14) on 64 female students with premenstrual syndrome (PMS) and physical inactivity showed that using social-media-based support through mobile applications could significantly reduce the PMS and promote physical activity compared to the control group.

The present study was performed to compare the effect of text messaging and that of mobile social networks on physical activity and anthropometric indices of middle-aged women in Iran.

## Methods

This was a randomized controlled trial (parallel design) in which 110 middle-aged women with physical inactivity were recruited and randomly assigned into two groups of text messaging and using social media to receive intervention for promoting physical activity. The inclusion criteria were age range of 40-60 years, basic digital literacy, having smart phone, access to the Internet, low score of International Physical Activity Questionnaire (IPAQ) or score of metabolic equivalent (MET)<600 per week. Women with following criteria were excluded from the study: prohibition from physical activity for medical reasons including class 3 and 4 heart disease, and severe arthritis, receiving another training program for physical activity, membership in a gym, and pregnancy.

The design of this study was approved by the Ethics Committee of Ahvaz Jundishapur University of Medical Sciences (Ref. No: IR.AJUMS.REC.1396.727) and the protocol was registered in the Iranian Registry of Randomized Clinical Trials (IRCT) (Ref. No: IRCT20170916036223N1, 29/12/2017). All participants provided written informed consent before data collection. This study started in November 2018 and completed in March 2019.

### Sample size

The following formula was used for sample size calculation:

$$n = \frac{(Z_{1-\alpha/2} + Z_{1-\beta})^2 (S_1^2 + S_2^2)}{(X_1 - X_2)^2}$$

$$\begin{array}{l} Z_{1-\alpha/2} = 1/96 \qquad Z_{1-\beta} = 1.28 \qquad S_1 = 6.5 \ S_2 = 6.9 \\ X_1 = 153 \qquad X_2 = 157.7 \qquad n = \frac{(1.96+1.28)^2(6.5+6.9)^2}{(153-157.7)^2} = 43 \end{array}$$

We considered 25% for attrition and the total sample size was calculated to be 55.

### Recruitment

Middle aged women that had been registered in two centers (a Menopausal Counseling clinic and a public health center) in Ahvaz, Iran received a phone call requesting them to participating in the study. A total of 131 women were assessed according to the eligibility criteria, of whom 110 were eligible and provided their consent to participate.

### Randomization

A random table generated by EXCEL was used for randomization (done by the study statistician). Due to the nature of this study, blinding of participants and researchers was not possible, but the code dedicated to each participant was kept with the secretary of the menopausal clinic, and neither the researcher nor the participants knew the code until the commencement of the trial.

### Measurements

A demographic questionnaire, a check list, and the International Physical Activity Questionnaire (IPAQ) were used for data collection. The demographic questionnaire included questions on age, age of menopause, level of schooling, marital status, occupation and number of children. The checklist was used to record anthropometric indices (height, weight, body mass index, waist circumference, hip circumference, waist/hip ratio, and percentage of body fat).

IPAQ contains 7 questions about physical activity over the past 7 days. It has three domains including physical activity related to work, leisure time, and home. In each domain, the number of days in which the person has been doing the activity for at least 10 minutes and the duration of physical activity in terms of day and minutes are asked. The intensity of total physical activity was calculated by means of metabolic equivalence (MET). Each MET represents the amount of energy consumed per minute for one person at rest. Each MET is equivalent to 3.5 milliliters of oxygen consumed per one kilogram of body weight. If the total energy expended for vigorous physical activity is 1500 MET/min/week in at least 3 days from the last 7 days, or if the total energy expended for a combination of moderate and vigorous physical activity or walking is 3000 MET/min/week, the intensity of physical activity is considered intense. Having intense physical activity for 3 days or more, having 5 days of moderate physical activity, walking for at least 30 minutes a day, or having intense activity with total energy expenditure equaling to 600 MET/week were considered as moderate-intensity physical activity. If there is no physical activity or the activities do not meet the above conditions, they are considered low intensity (15). The IPAQ was developed by an international group in Geneva in 1998. This questionnaire is adapted for the determination of physical activity of adults aged 15-69 and has been used in numerous studies in different countries. The validity and reliability of this questionnaire has been approved in Iran by Baghiani et al (16).

To measure the participants' height and weight, two digital scales (Omron, China made) were used respectively. The weight of the participants was measured as they were barefoot in light clothing. Their height was measured with the Omron stadiometer, while they were standing barefoot. To measure the girth of the waist and hips, a flexible measuring tape was used. The German Bauer diagnostic scale (BG64 USB) was used for measuring body fat percentage. After turning on the device, it was placed on a flat surface and the women were requested to step barefooted. Participants' characteristics, such as age, gender, weight, and level of physical activity were recorded in the device. The percentages of body fat, water, muscle, and bone mass, as well as basal metabolism were measured and recorded. All measurements were done by a trained midwife.

## **Intervention**

The two groups were given instructions to promote their physical activity either through text messaging or mobile social networking. For the social networking group, a Telegram group was set up and all women (n=55) were asked to join this group. Both groups received information about the need for physical activity, the benefits of physical activity, barriers to doing physical activity, and how to overcome these barriers. Women in the text messaging group received text messages involving the same content as that presented to the mobile social networking group three times a week.

The women in two groups were requested to complete IPAQ prior to the intervention, as well as four, eight and twelve weeks after the intervention. Furthermore, anthropometric indices were measured over the aforementioned periods. All women kept journals to record their physical activity. Upon completion of the study, individuals from both groups received payment for their Internet usage (CONSORT checklist, supplementary material 1).

## **Statistics**

Data analysis was performed using SPSS version 23. To compare the quantitative variables in the two groups, the independent t-test was used if the distribution was normal, and if it was not normal, the Mann-Whitney test was used, which was also used for qualitative variables. The Chi-square test was used for nominal or qualitative data. Paired t-test and Wilcoxon test were used for within group comparisons before and after the intervention. To compare the changes in each group in weeks 4, 8, and 12, the repeated measures test was used if the data were normal, and otherwise, the Friedman test was used. The significance level was set at <0.05.

## **Results**

In this study 110 women were recruited, and there were not any dropouts (Fig. 1). The demographic characteristics of participants are listed in Table 1. The age of participants was  $52.12 \pm 6.07$  and  $51.18 \pm 5.85$  in the text messaging and mobile social networking groups respectively. The two groups did not show any significant difference regarding demographic characteristics.

Table 1  
Demographic characteristics of participants in two groups of text message and mobile social networking

Variable	Text message N = 55	Mobile Social networking N = 55	P value
	Mean $\pm$ SD		
Age (y)	52.12 $\pm$ 6.07	51.18 $\pm$ 5.85	0.409
Marital status			
Married	52 (94.5)	53(96.4)	0.64
Single	3(5.5)	2(3.6)	
Education			
High school	9(16.3)	7(12.7)	0.89
Diploma	31(56.3)	36(65.4)	
University education	15(26.2)	11(21.8)	
Menopausal status			
Menopause	38(69.1)	31(56.4)	0.16
Pre-menopause	17(30.9)	24(43.6)	

Table 2 shows the physical activity of participants in two groups of text message and mobile social networking. As evident in this table, most of the participants were inactive before the intervention, while after the intervention, 81.8% of participants in the text message and 14.5% of the participants in mobile social networking group had low and moderate physical activity. In the mobile social networking group, after 12 weeks, 23.6% and 72.7% of participants had low and moderate physical activity, respectively ( $p < 0.05$ ).

Table 2  
Physical activity of participants in two group of text message and mobile social networking

Groups' Physical activity	Before intervention	4-weeks after intervention	8 weeks after intervention	12 weeks after intervention	P Value using repeated measure test
	No (%)				
<b>Text message (N = 55)</b>					< 0.001
Inactive	25(45.5)	18(32.7)	7(12.7)	2(3.6)	
Low	29(52.7)	30(54.5)	43(78.2)	45(81.8)	
Moderate	1(1.8)	7(12.7)	5(9.1)	8(14.5)	
<b>Mobile social networking N = 55</b>					
Inactive	17(30.9)	7(12.7)	3(5.5)	1(1.8)	
Low	38(69.1)	34(61.8)	22(40)	13(23.6)	
Moderate	0	14(25.5)	30(54.5)	40(72.7)	
Vigorous	0	0	0	1(1.8)	
<b>P value</b>	0.15	0.008	0.001	0.001	

Table 3 shows the mean physical activity in two groups of text message and mobile social networking. Before intervention, the two groups did not show any significant difference in terms of mean physical activity. Four weeks after the intervention, however, the mean of physical activity in text messaging group was higher than that in social networking ( $p = 0.008$ ). The mean of physical activity in the mobile networking group compared to the text messaging group was significantly higher in the 8th week ( $2.89 \pm 0.64$  vs.  $2.71 \pm 0.49$ ,  $p = 0.001$ ) and 12th week of the intervention ( $3.30 \pm 0.49$  vs.  $2.99 \pm 0.49$ ,  $p = 0.001$ ) compared to the text messaging. The mean of energy expenditure in the 4th, 8th, and 12th weeks after intervention was also higher in the mobile social networking group in comparison to the text messaging group ( $p = 0.001$ ).

Table 3  
The mean intensity of physical activity in two groups of text message and mobile social networking

Variable	Text message N = 55	Mobile Social networking N = 55	P value for t-test	P value for repeated measure
<b>Physical activity</b>	Mean ± SD			
Before intervention	1.92 ± 0.24	1.55 ± 0.01	0.07	< 0.001
4 weeks after intervention	2.38 ± 0.54	2.26 ± 0.57	0.008	
8 weeks after intervention	2.71 ± 0.49	2.89 ± 0.64	0.001	
12 weeks after intervention	2.99 ± 0.49	3.30 ± 0.49	0.001	
P value	0.001	0.001		
<b>Energy expenditure during past week</b>				
Before intervention	205.4 ± 374.4	81.3 ± 90.62	0.19	< 0.001
4 weeks after intervention	382.5 ± 475.4	762.7 ± 676.9	0.001	
8 weeks after intervention	475.7 ± 419.1	1196.5 ± 764.8	0.001	
12 weeks after intervention	555 ± 518.9	1631.3 ± 828	0.001	
P value	0.001	0.001		

The means of body weight and body mass index (BMI) before and after intervention are listed in Table 4. Participants of the two groups did not show any significant difference before the intervention, as well as in the 4th, and 8th weeks of intervention regarding weight and BMI. However, in the 12th week of intervention, participants in the mobile social networking group lost more weight and the reduction in their BMI was more pronounced compared to the text messaging group ( $p < 0.05$ ).

Table 4

Mean weight and body mass index, 4, 8, and 12 weeks after intervention in two groups of text message and mobile social networking

Variable	Text message N = 55	Mobile social networking N = 55	P value	P value for repeated measure test
	Mean $\pm$ SD			
<b>Weight</b>				
Before intervention	79.16 $\pm$ 14.5	76.07 $\pm$ 10.08	0.19	0.08
4 weeks after intervention	78.6 $\pm$ 14.5	74.8 $\pm$ 10.3	0.17	
8 weeks after intervention	78.3 $\pm$ 14.4	73.9 $\pm$ 10.1	0.06	
12 weeks after intervention	77.9 $\pm$ 14.5	72.7 $\pm$ 10.03	0.03	
P value	0.02	0.001		
<b>Body mass index (kg/m<sup>2</sup>)</b>				
Before intervention	31 $\pm$ 5.5	29.9 $\pm$ 4	0.26	0.12
4 weeks after intervention	30.6 $\pm$ 5.23	29.5 $\pm$ 4.1	0.25	
8 weeks after intervention	30.6 $\pm$ 5.4	29.1 $\pm$ 4.06	0.09	
12 weeks after intervention	30.7 $\pm$ 5.8	28.6 $\pm$ 4.06	0.03	
P value	0.43	0.001		

Table 5 shows the anthropometric indices of the participants before and after the intervention. The waist circumference of women in the text messaging group before intervention was significantly more than that in the social networking group ( $p = 0.01$ ). Four weeks after the intervention, the waist circumference of women in the text messaging reduced significantly compared with the mobile social networking group ( $p = 0.01$ ), while in the 8th week of the intervention, the two groups did not show any significant difference in this regard. Twelve weeks after the intervention, the waist circumference of women in social networking group reduced significantly compared with the text messaging group ( $p = 0.001$ ). The hip circumference of women in the mobile social networking group reduced significantly compared with the text messaging group 4, 8, and 12 weeks after intervention. Two groups did not show any significant difference regarding waist/hip ratio.

Table 5

Mean of anthropometric indices in two groups of text message and mobile social networking in 4, 8, and 12 weeks after intervention

Variable	Text messaging N = 55	Mobile Social networking N = 55	P value	P value for repeated measure test
	Mean $\pm$ SD			
<b>Waist circumference (cm)</b>				
Before intervention	96.8 $\pm$ 12.01	90.8 $\pm$ 13.1	0.01	0.006
4 weeks after intervention	95.5 $\pm$ 11.7	90.6 $\pm$ 8.17	0.01	
8 weeks after intervention	93.6 $\pm$ 16.5	89.2 $\pm$ 8.7	0.08	
12 weeks after intervention	94.3 $\pm$ 11.8	87.8 $\pm$ 8.4	0.001	
P value	0.003	0.001		
<b>Hip circumference (cm)</b>				
Before intervention	111.7 $\pm$ 10.9	108.4 $\pm$ 8.9	0.09	0.01
4 weeks after intervention	109.5 $\pm$ 10.9	105 $\pm$ 8.01	0.01	
8 weeks after intervention	108.6 $\pm$ 11.2	103.2 $\pm$ 8.3	0.005	
12 weeks after intervention	107.7 $\pm$ 11.7	101.6 $\pm$ 8.1	0.002	
P value	0.001	0.001		
<b>Waist hip ratio</b>				
Before intervention	0.86 $\pm$ 0.06	0.85 $\pm$ 0.05	0.35	0.36
4 weeks after intervention	0.86 $\pm$ 0.06	0.85 $\pm$ 0.05	0.35	
8 weeks after intervention	0.87 $\pm$ 0.07	0.86 $\pm$ 0.06	0.3	
12 weeks after intervention	0.87 $\pm$ 0.06	0.86 $\pm$ 0.06	0.41	
P value	0.10	0.26		
<b>Body fat percentage</b>				
Before intervention	40.3 $\pm$ 5.6	40.3 $\pm$ 4.8	0.92	0.34
4 weeks after intervention	40.4 $\pm$ 5.4	39.5 $\pm$ 5.03	0.37	
8 weeks after intervention	40.2 $\pm$ 5.3	39.1 $\pm$ 4.9	0.28	
12 weeks after intervention	40.3 $\pm$ 5.1	38.5 $\pm$ 4.8	0.05	
P value	0.4	0.001		

While body fat percentage was reduced in the mobile social networking group in the 4th, 8th, and 12th weeks of intervention, but the differences between the two groups were not significant.

## Discussion

This study was designed to compare the effects of text messaging and mobile social networking on physical activity and anthropometric indices of middle-aged Iranian women. Our results showed that the frequency and the mean of physical activity significantly increased in the mobile social networking group compared to women in the text-messaging group. Also, the mean energy expenditure per week was significantly higher in the mobile social networking compared the text messaging group.

In their study on 12 overweight or obese middle-aged women, Arigo et al. (17) found that connected networking and an automated physical activity sensor for four weeks could significantly promote the physical activity of these women. Peyman et al. (18) conducted a quasi-experimental study on 360 women and found that using media-based educational intervention for eight weeks could significantly increase the level of physical activity of women in the intervention group compared to the control group. The results of the present study are similar to those of Arigo et al. and Peyman et al.

Our results revealed there was a significant reduction in the weight and BMI of the participants in the mobile social networking group compared to the text messaging group. Similar to our results, Silina et al. in their study on 123 healthy overweight and obese individuals found that using text messaging could significantly reduce weight, body mass index, waist circumference, hip circumference, and fasting insulin after one year compared to the control group (19).

Our results revealed that waist and hip circumferences reduced significantly in the mobile social networking compared to the text messaging group. However, there were no significant differences between the groups in terms of waist/hip ratio and the body fat percentage. Increased waist circumference, BMI, and waist/hip ratio is a risk factor for coronary heart disease, and diabetes type 2 (20). Sillina et al. found that weight, BMI, and WC decreased significantly in the intervention group who received instruction through text messaging in comparison to the control group after a one-year intervention(19), which is consistent with our results. Although there was a significant reduction in anthropometric indices such as weight, BMI, WC, and HC, the waist/hip ratio and body fat percentages did not decrease significantly, indicating that women need more than 12 weeks to achieve significant results regarding these two factors.

### **Strengths and limitations of the study**

This was the first study to compare the effects of text messaging and mobile social networking on improving physical activity and anthropometric indices among middle-aged women. However, it has certain limitations. First, we relied on responses of women about their physical activity level, which might be affected by recall bias. In this study, the participants and researchers were not blinded, and therefore the results may be affected by performance bias. For reducing this bias, all outcomes were measured by a single person who was not aware of the purpose of the study.

## **Conclusion**

Both text messaging and mobile social networking were effective in promoting physical activity and reducing anthropometric indices except for waist/hip ratio and body fat percentages, but the effect of mobile social networking was more pronounced. Thus, mobile social networking is recommended for promoting physical activity among middle-aged women.

## **Abbreviations**

PMS: Premenstrual syndrome

IPAQ: International Physical Activity Questionnaire

MET: Metabolic Equivalent

BMI: Body Mass Index

WC: Waist Circumference

## **Declarations**

**Ethics approval and consent to participate:** This study was approved by the Ethics Committee of Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran (Ref No: IR.AJUMS.REC.1396.727). All methods were performed in accordance with the relevant guidelines and regulations. All participants provided written informed consent before data collection

**Consent for publication:** NA

**Availability of data and materials:** The datasets generated and/or analyzed during the current study are not publicly available due to restrictions (Ahvaz Jundishapur University of Medical Sciences does not permit to data publicity before publication) but are accessible through the corresponding author upon reasonable request.

**Competing interests:** Authors do not have any competing interest.

**Funding:** All expenses of this study were provided by Ahvaz Jundishapur University of Medical Sciences, which did not have any role in the design, data collection, data analysis and interpretation, or submission of the manuscript.

**Authors' contributions:** Kousar Ansari, Poorandokht Afshari, and Parvin Abedi were involved in the design of the study. Kousar Ansari collected the data. Kousar Ansari, Poorandokht Afshari, Parvin Abedi, and Mohammadhossein Haghhighizadeh contributed to data analysis and interpretation. Parvin Abedi prepared the manuscript in English. All authors reviewed the manuscript.

## Acknowledgements

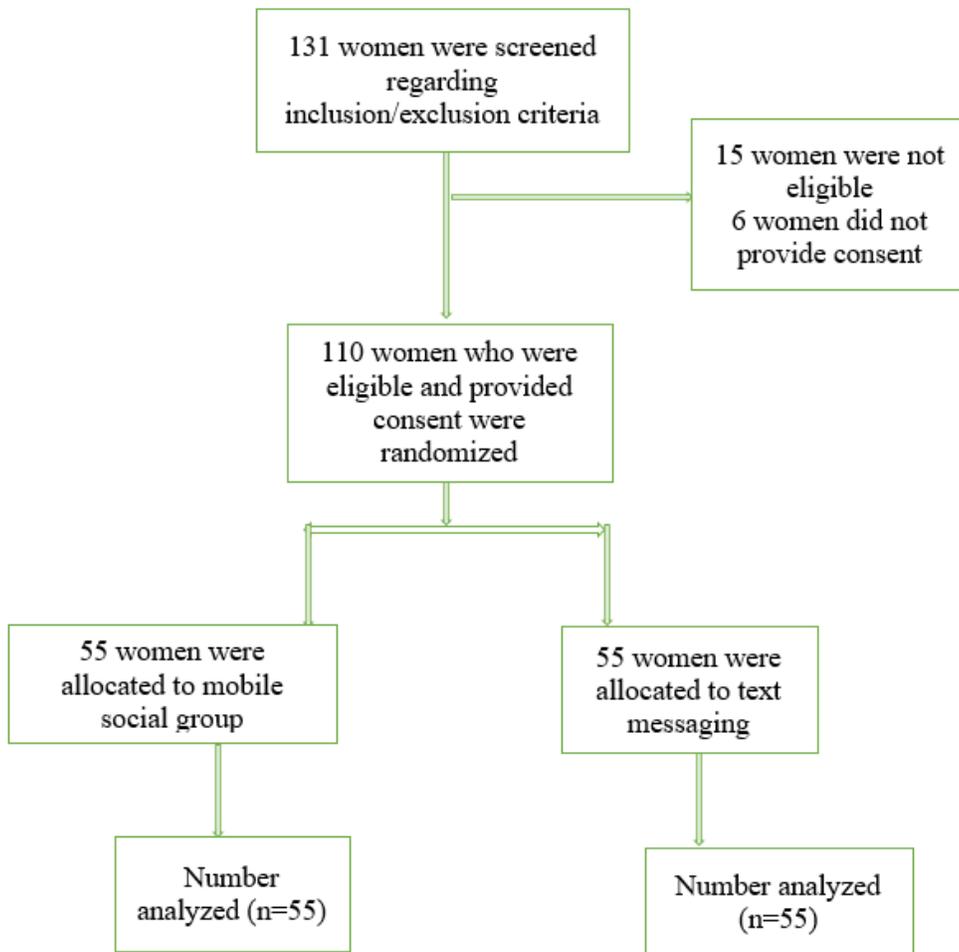

This study was extracted from the master's thesis of KA. We would like to thank all women who participated in this study. We also would like to thank Dr. Mahmoud Maniati as he edited this manuscript.
