Version of Record: A version of this preprint was published at BMC Cancer on April 1st, 2021. See the published version at <https://doi.org/10.1186/s12885-021-07953-y>.

Abstract

Background: To investigate factors that affects postoperative recurrence in medullary thyroid carcinoma (MTC) patients in terms of preoperative ultrasonic characteristics and so on.

Method: A retrospective analysis of 74 MTC patients who underwent the first thyroid surgery from 2009 to 2018 at hospital and had complete follow-up information. According to the follow-up results, these patients were divided into recurrence group (17 cases) and non-recurrence group (57 cases). The preoperative ultrasound characteristics, preoperative and postoperative calcitonin level, and general information of the two groups were recorded separately. Univariate and multivariate analysis was performed.

Results: Single factor KM analysis showed that: Preoperative ultrasonic characteristic of tumor size > 40.0 mm, capsular invasion, and abnormal cervical lymph node, as well as preoperative calcitonin level > 565.8pg / ml, postoperative calcitonin (within one week) level > 45.0pg / ml are the factors that affect postoperative recurrence of MTC ($P < 0.05$); There is no evidence shows that gender and age have statistical significance with postoperative recurrence of MTC patients ($P > 0.05$). Multi-factor COX regression analysis showed that abnormal cervical lymph node $HR = 5.368, 95\%CI 1.063-27.104, P = 0.042$ is an independent risk factor affecting postoperative recurrence of MTC patients.

Conclusions: MTC patients with abnormal cervical lymph nodes prone to postoperative recurrence. In addition, MTC patients with tumor > 40.0mm, capsular invasion, preoperative calcitonin level > 565.8pg / ml, postoperative calcitonin level > 45.0pg / ml are more likely to have postoperative recurrence.

1. Background

Medullary Thyroid Carcinoma (MTC) originates from parafollicular cell (C cell), and its incidence is only 1-2% of thyroid carcinoma [1]. Ultrasound is the first choice for thyroid disease. MTC tumors often show preoperative ultrasonic characteristics such as solidity, low echo, calcification, and clear boundaries [2-3]. Medullary thyroid carcinoma is a moderate malignant tumor with a high recurrence rate (44.1% -47.3%) [4-5]. At present, researches about the factors affecting MTC recurrence mostly focus on surgical methods, calcitonin (or procalcitonin), pathology, etc. [4-6], while researches about preoperative ultrasound characteristics of MTC are relatively rare. Therefore, this study attempted to study the factors that affect the postoperative recurrence of MTC based on the preoperative ultrasonic characteristics, preoperative and postoperative calcitonin level and general information of MTC patients.

2. Methods

2.1 Clinical data

A retrospective analysis of 74 MTC patients who were admitted to the Hospital from 2009 to 2018 and had complete follow-up data. All patients underwent unilateral thyroid lobe plus isthmus excision or total

thyroidectomy and central cervical lymph node dissection, and for those who were suspected of lateral cervical lymph node metastasis by preoperative clinical and imaging evaluation and confirmed by fine needle biopsy, lateral cervical lymph node dissection would be performed. All the patients were confirmed to be MTC by pathology.. According to the follow-up pathological results of the second operation, the cases were divided into recurrence group (17 cases ,23%) and non-recurrence group (57 cases ,77%). Inclusion criteria are that patients have initial thyroid surgery in our hospital, completed follow-up data, preoperative ultrasonic examination, postoperative pathological confirmation of MTC, secondary postoperative pathological confirmation of cervical lymph node recurrence. Exclusion criteria are that patients with a previous history of thyroid surgery, follow-lost patients, and cases of death. Unilateral thyroid lobe plus isthmus excision or total thyroidectomy were performed on all patients. This study was approved by the Ethics Committee of our hospital, and all patients in this study had signed informed consent forms.

2.2 Methods

2.2.1 Examination methods: All 74 patients underwent preoperative ultrasonic examination, using ultrasound diagnostic equipment such as Philips iU22 (L12-5 linear array probe, frequency 7.5 ~ 14MHz), GE Logiq E9 (ML6-15 linear array probe, frequency 6 ~ 15MHz). The patient had the supine position, head back to expose the neck, scanned and recorded the number, size, location, echo, composition, shape, boundary, aspect ratio, capsular invasion, calcification, blood flow and other information.

2.2.2 Image analysis: Two ultrasound attending physicians who have worked for more than 5 years independently analyzed the pre-stored images using the double-blind method. If the results are inconsistent, the ultrasound (associate) chief physician would be asked to assist in the analysis. Ultrasound image analysis includes the number of thyroid tumors (single focus, multiple focus), size ($\leq 40.0\text{mm}$, $> 40.0\text{mm}$), boundary (clear, unclear), composition (solid, cystic, cystic solid), morphology (regular, irregular), echo (very low echo, low echo, equal echo, high echo), aspect ratio (Front and back diameter/ Left and right diameter ≥ 1 , Front and back diameter/ Left and right diameter < 1), capsular invasion (yes , no), calcification (yes, no), blood flow (rich, none) abnormal cervical lymph node yes ,no. If patients had multiple masses, the largest tumor was selected for analysis.

2.2.3 Collection of calcitonin: preoperative calcitonin was obtained from patients within 3 days before surgery, and postoperative calcitonin was obtained from patients within 7 days after surgery.

2.3 Statistical analysis

SPSS25.0 statistical software was used for statistical analysis. Measurement data is expressed as mean $\pm$ standard deviation. The single factor K-M method was used for survival analysis, and the log-rank method was used for survival analysis. Multi-factor test uses COX regression analysis. $P < 0.05$ was considered statistically significant.

3. Results

A total of 74 MTC patients were followed up from the date of diagnosis to November 30, 2019, with recurrence as the end event. Follow-up was 14.5 to 128.9 months, median follow-up time was 42.0 months, and 17 patients (23%) during the follow-up period patients relapsed and the average healthy survival time was (40.4 ± 3.2) months. The 1, 3, 5, and 10 years of overall healthy survival rates were 91.9%, 81.1%, 78.4%, and 77.0%, respectively.

3.1 General information:

A total of 74 MTC patients, including 42 males (56.8%) and 32 females (43.2%); aged 8 to 77 years, with an average of 49.6 ± 1.6 years. According to the postoperative pathological results, it was divided into 17 cases (23%) in recurrence group and 57 cases (77%) in non-recurrence group. The age (continuous variable) and recurrence (binary classification variable) were analyzed by ROC curve, and the optimal cut-off value was 52.50 years old [AUC=0.578]Sensitivity=0.706]Specificity=0.467]. Therefore, the age is divided into ≤52.50 years old and > 52.50 years old. General data single-factor K-M survival analysis showed that there is no evidence shows that gender and age have statistical significance with the postoperative recurrence of MTC patients (P> 0.05). Details are shown in Table-1.

Table-1 Results of single factor K-M analysis related to recurrence of MTC patients

group	character	recurrence group(cases)	Non- recurrence group(cases)	Chi-square	P
Gender	male	12	30	1.542	0.214
	female	5	27		
Age	≤52.5	12	31	0.925	0.336
	>52.5	5	26		
Preoperative calcitonin(a*)	≤565.8pg/ml	1	25	6.363	0.012
	>565.8pg/ml	11	23		
Postoperative calcitonin(b*)	≤45.0pg/ml	1	33	12.786	0.00349
	>45.0pg/ml	15	21		
Tumor size	≤40.0mm	13	53	5.837	0.016
	>40.0mm	4	4		
Encroachment on the envelope	no	1	29	9.273	0.002
	yes	16	28		
abnormal cervical lymph nodes	no	2	31	8.442	0.004
	yes	15	26		

*Notes: a. 60 cases with preoperative calcitonin; b. 70 cases with postoperative calcitonin.

3.2 Calcitonin:

Among the 74 patients, only 60 cases had preoperative calcitonin and only 70 cases had postoperative calcitonin. The normal reference range of calcitonin was 0-10pg / ml. The range of calcitonin before surgery is 3.5-2000.0pg / ml, and the range of postoperative calcitonin is 0.5-2000.0pg / ml. Preoperative calcitonin was normal in 2 cases and elevated in 58 cases. Postoperative calcitonin was normal in 18 cases and elevated in 52 cases. The preoperative calcitonin value (continuous variable) and recurrence (binary variable) were analyzed by ROC curve, and the best diagnostic cutoff value was 565.8pg / ml $AUC=0.745$ Sensitivity=0.917 Specificity=0.519. There were 26 cases preoperative calcitonin ≤ 565.8 pg / ml, and 34 cases > 565.8 pg / ml. The ROC curve analysis of postoperative calcitonin value (continuous variable) and recurrence (binary variable) was carried out, and the best diagnostic cut-off value was 45.045pg / ml $AUC=0.759$ Sensitivity=0.938 Specificity=0.611. Among them, 34 cases of postoperative calcitonin ≤ 45.0 pg / ml, 36 cases of > 45.0 pg / ml. The single factor K-M survival analysis showed that preoperative calcitonin > 565.8 pg / ml and postoperative calcitonin > 45.0 pg / ml are the factors that affect the recurrence of MTC patients ($P < 0.05$). Details are shown in Table-1.

3.3 Ultrasound characteristics analysis:

17 cases in recurrence group: the size of thyroid tumors under ultrasound was 8.0 to 61.0mm, with an average of 28.18 ± 14.66 mm. 57 cases in the non-recurrence group: the size of the thyroid tumor under ultrasound was 5.0 to 55.0 mm, with an average of 18.68 ± 11.57 mm. The tumor of 74 patients was divided into ≤ 40.0 mm group and > 40.0 mm group with 40.0mm as the boundary. In addition, the thyroid tumors in the recurrence group and the non-recurrence group were more characterized by single focus, solid, low echo, clear boundary, irregular morphology, aspect ratio (front and back diameter/ Left and right diameter) < 1 , calcification, and blood flow signal. The single factor K-M survival analysis showed that the tumor > 40.0 mm, capsular invasion, and abnormal cervical lymph nodes were the survival factors affecting the recurrence of MTC patients ($P < 0.05$). Details are shown in Table-1. The corresponding ultrasonic characteristics are shown in Fig.1. However, there is no evidence shows that the number, composition, echo, boundary, morphology, aspect ratio, calcification and blood flow have statistical significance with the postoperative recurrence of MTC patients ($P > 0.05$) through single-factor K-M survival analysis. Details are shown in Table-2.

Table 2—Results 2 of single factor K-M analysis of ultrasound characteristics related to recurrence of MTC patients

group	character	recurrence group(cases)	Non- recurrence group(cases)	Chi- square	P
number	single focus	10	42	0.847	0.357
	multiple focus	7	15		
composition	solid	16	51	0.605	0.437
	cystic solid	1	6		
	cystic	0	0		
echo	very low echo	3	17	1.119	0.773
	low echo	12	36		
	equal echo	2	3		
	high echo	0	1		
boundary	clear	10	41	1.370	0.242
	unclear	7	16		
morphology	regular	4	26	2.609	0.106
	irregular	13	31		
aspect ratio (Front and back diameter/ Left and right diameter)	≥1	2	5	0.023	0.881
	<1	15	52		
calcification	yes	12	36	0.525	0.469
	no	5	21		
blood flow*	yes	12	38	0.337	0.562
	no	2	11		

*Notes: Only 63 patients with ultrasonic figure of blood flow.

3.4 Multi-factor COX regression analysis:

3 ultrasonic characters were used to construct a multi-factor COX regression equation, including the size of the tumor, capsular invasion, and the abnormal cervical lymph nodes. As a result, abnormal cervical

lymph nodes [HR=5.368,95%CI1.063-27.104]P=0.042]was MTC patient’s independent risk factor for recurrence. Details are shown in Table-3.

Table-3 Multi-factor COX regression analysis results

group*	B	Degree of freedom	P	HR	95%CI
Tumor size	0.853	1	0.153	2.347	0.728-7.570
Capsular invasion	2.181	1	0.050	8.855	0.996-78.730
Abnormal cervical lymph nodes	1.680	1	0.042	5.368	1.063-27.104

* Note: tumor Size (1 is ≤ 40.0mm, 2 is>40.0mm), Capsular invasion (0 no, 1 yes), abnormal lymph nodes in the neck (0 no, 1 yes).

4. Discussion

MTC accounts for an extremely small proportion of thyroid carcinoma and is a moderate malignant carcinoma, and for it is derived from C cells, its biological characteristics and malignant degree differ from other types of thyroid carcinoma derived from thyroid follicular cells. MTC is prone to recurrence after operation. In this study, the recurrence rate after MTC reached 23% (17/74), which was lower than the recurrence rate reported in the previous literature (44.1% -47.3%) [4-5].

In terms of general information, through univariate analysis, Zhang Zaixing et al [6] fund that gender (female) and age (≥45 years) were important factors affecting survival (recurrence, death, etc.) (P <0.05). Through multifactorial analysis, Hassan et al. [4] found that gender(male) was the poor prognostic factors (recurrence, death, etc.) of MTC patients (P <0.05). In this study, the recurrence group and the non-recurrence group were more often to be male and young (≤52.5 years old), and there was no statistical significance between gender, age and recurrence (P> 0.05). The conclusions obtained in this study are partially consistent and partially contradictory with the conclusions of the above studies, which are related to the different definitions of the ending of the three studies and the small number of cases.

MTC is derived from C cells that secrete calcitonin, so it has the characteristic expression of elevated calcitonin. Some studies have found that patients with MTC who still have elevated postoperative calcitonin were more prone to have cervical lymph node metastasis and recurrence [7]. Through multivariate analysis, Hassan et al. [4] found that MTC patient’s postoperative calcitonin doubling time less than two years and that the rate of increase in calcitonin value greater than 0.05 pg/ml/month were poor prognostic factors (P <0.05). A study through meta-analysis showed that procalcitonin can be used as a marker for postoperative follow-up monitoring of MTC patients to monitor recurrence [5]. In this study, single factor KM survival analysis showed: preoperative calcitonin> 565.8pg / ml, postoperative calcium Factors> 45.0 pg/ml are factors that affect the recurrence of MTC patients (P <0.05, see Table-1). Only 60 cases had preoperative calcitonin and only 70 cases had postoperative calcitonin, so they were

not included in the multivariate analysis. The conclusion that there is statistical significance between the elevated calcitonin (or procalcitonin) and the recurrence of MTC patients is not new, and the specific values of calcitonin (or procalcitonin) that affect recurrence are not the same in each study. This is related to the limited number of cases enrolled in various studies, the large age span, and different test levels.

Starting from the ultrasonic features of medullary thyroid carcinoma, the research on exploring the relationship between MTC and cervical lymph node metastasis is relatively extensive, while there are relatively few studies on the relationship between preoperative ultrasonic features and recurrence of MTC. Studies have pointed out that in sporadic medullary thyroid carcinoma, single-factor chi-square analysis believes that patients with tumors > 15 mm, irregular morphology, sharp edges, and masses located under the capsule have a higher risk of lateral neck lymph node metastasis ($P < 0.05$) [8]. The ultrasound characteristics of medullary thyroid carcinoma mass include the size, number, echo, composition, boundary, morphology, invasion of the capsule, aspect ratio, calcification, blood flow, etc. In this study, single factor KM analysis showed that the tumor ≥ 40.0 mm, capsular invasion, and abnormal cervical lymph nodes were the survival factors affecting the recurrence of MTC patients ($P < 0.05$). These three factors represent the size of the tumor, the relationship with the surrounding adjacent tissues, and the status of the lymph nodes, which can be further applied to the preoperative T and N stages of MTC patients. Some studies have shown that T4 is a poor prognostic factor through multi-factor analysis [4], and some studies have shown that TNM staging is a factor affecting prognosis through single factor analysis [6]. The results of the multi-factor COX regression analysis in this study showed that abnormal cervical lymph node was the only independent risk factor affecting the recurrence of MTC patients. In addition, this study found that in the recurrence group and the non-recurrence group, the tumors were mostly characterized by solidity, low echo, clear boundaries, and calcification. There were no statistically significant differences between the ultrasound features such as the composition, echo, boundary, calcification and recurrence of MTC patients.

In this study, the results of univariate KM analysis showed that: tumor > 40.0 mm, capsular invasion, abnormal cervical lymph nodes, preoperative calcitonin > 565.8 pg/ml, postoperative calcitonin > 45.0 pg/ml are the effects factors of MTC recurrence ($P < 0.05$). The results of multi-factor COX regression analysis showed that abnormal cervical lymph node $HR = 5.368, 95\%CI 1.063-27.104, P = 0.042$ is independent risk factors affecting the recurrence of MTC patients. MTC patients with abnormal cervical lymph nodes are more likely to relapse. Calcitonin was not included in the multivariate analysis, but to a certain extent, preoperative calcitonin > 565.8 pg/ml, postoperative calcitonin > 45.0 pg/ml can also indicate more likely to relapse.

In this study, a total of 74 patients with MTC, including 17 cases of recurrence during follow-up, 57 cases of non-recurrence, and 2 death cases were not included in the study. The conclusion of this study is that the ultrasound features can be used for preoperative T and N staging, but no factors related to recurrence have been found from other ultrasound features such as the composition, echo, boundary, and calcification. At the same time, the number of recurrence cases in this study did not reach half of the total

number of cases, and the median survival time could not be obtained in the K-M survival analysis. The follow-up study can be continued in the future.

6. Declarations

6.1 Ethics approval and consent to participate

This study was approved by the Ethics Committee of our hospital, and all patients in this study had signed informed consent forms. In this study, written informed consent for participation was obtained where participants are children (under 16 years old) from their parent or guardian.

6.2 Consent for publication

This study was approved by our hospital for publication.

6.3 Availability of data and material

I can confirm I have included a statement regarding data and material availability in the declaration section of my manuscript.

6.4 Competing interests

We have no competing interests in the work.

6.5 Funding

This work was supported by the National Natural Science Foundation of China[grant number 81871370];and the Natural Science Foundation of Zhejiang Province (CN) [grant number LSD19H180001].

6.6 Authors' contributions

We certify that we have participated sufficiently in the work to take public responsibility for the appropriateness of the experimental designs and methods, and the collection, analysis, and interpretation of the data.

6.7 Acknowledgements

Not applicable.
