# Abstract

**Background:** Since the outbreak of the Syrian war in 2011, close to 6 million Syrian refugees have escaped to Syria's neighbouring countries, including Lebanon. Evidence suggests rising levels of mental health disorders among Syrian refugee populations. Yet, to the best of our knowledge, large-scale studies addressing the mental health of adult Syrian refugees in Lebanon are lacking.

**Aims:** We examined the prevalence of depression symptoms, which represent a common and debilitating mental health disorder among Syrian refugee populations in Lebanon, along with their sociodemographic and clinical correlates.

**Methods:** A cross-sectional survey design was conducted as part of a collaborative project-"Sijilli"- led by the Global Health Institute at the American University of Beirut (Beirut, Lebanon) across 4 informal tented settlements for refugees (Beirut, Bekaa, North, South) in Lebanon among adult Syrian refugees ( $\geq 18$ ), over a period extending from 2018 to 2020. The survey inquired about participants' sociodemographic and clinical characteristics, and screened participants for symptoms of depression through sequential methodology using the Patient Health Questionnaire (PHQ-2 and PHQ-9).

**Results:** A total of 3255 adult Syrian refugees were enrolled in the study. Of those refugees, only 51.6% ( $n=1678$ ) screened positive on the PHQ-2 and were therefore eligible to complete the PHQ-9. The PHQ-9 analysis revealed high prevalence (25%) of moderate to severe depression in the total sample, suggestive of high probability for major depression disorder (MDD). Further analyses indicate that being  $\geq 45$  years of age (OR 1.70, 95% CI 1.22-2.36), a woman (OR 1.35, 95% CI 1.07-1.69), divorced/separated (OR 3.32, 95% CI 1.57-7.01), reporting a neurological (OR 1.77, 95% CI 1.20-2.61) or a mental health condition (OR 5.30, 95% CI 2.40-11.66) are major risk factors for MDD.

**Conclusion:** Our study suggests that one in four Syrian refugees in Lebanon have probable MDD, and our findings have important public health and clinical implications on refugee health. There is a need to enhance screening efforts, to improve access and referral to mental health services, and to improve post-migration factors among Syrian refugees in Lebanon.

## 1. Introduction

The Syrian crisis has been widely described as one of the largest refugee crises of recent times (Nadim Almoshmosh, Jefee Bahloul, Barkil-Oteo, Hassan, & Kirmayer, 2019; Hassan, Ventevogel, Jefee-Bahloul, Barkil-Oteo, & Kirmayer, 2016). Close to 6 million Syrian refugees have fled to Syria's neighbouring countries, namely Lebanon, Jordan, Turkey, Egypt, and Iraq (UNHCR, 2018). Lebanon currently hosts over 1.5 million Syrian refugees, a number equivalent to 25% of its population (Refaat & Mohanna, 2013), rendering it the country with the largest number of refugees per capita worldwide (Knudsen, 2016). The massive influx of Syrian refugees to Lebanon, coupled with their increased demand for healthcare services, has significantly strained the country's already fragile healthcare system, and has hindered its ability to cater to their health needs (El Chammay & Ammar, 2014; E. Karam et al., 2016).

Having escaped from conflict settings, refugees often experience a multitude of stressors such as traumatic events, multiple forms of losses, discrimination, and acculturation difficulties among others during their journey of displacement (Hassan et al., 2016). They have therefore significantly higher odds of developing mental health disorders compared to the general population (Hassan et al., 2016). Many refugees are survivors of exploitation, torture, and sexual and gender-based violence, which further exacerbate their vulnerability to health conditions (Hassan et al., 2016). That said, they are less likely to receive mental health services because of social stigma, language and cultural barriers, imbalanced power dynamics with service providers, limited access to services, and low mental health literacy, including lack of perceived need (Abou-Saleh & Hughes, 2015; Hassan et al., 2016; Jefee-Bahloul, Moustafa, Shebl, & Barkil-Oteo, 2014; Weine, 2011). Recent evidence indicates that mental health is one of the most pressing health needs among Syrian refugees in Lebanon and neighbouring countries (El Arnaout et al., 2019).

Major Depressive Disorder (MDD), Post-Traumatic Stress Disorder (PTSD), and other anxiety disorders have been reported as the most common mental health disorders among Syrian refugees (Acarturk et al., 2018; Georgiadou, Zbidat, Schmitt, & Erim, 2018), and they tend to be comorbid conditions. In the general population, MDD in particular, is the third leading cause of years lived with disability (YLDs) (IHME, 2020), and is considered a strong risk factor for suicide (May & Klonsky, 2016; Rogers, Ringer, & Joiner, 2018). Therefore, depression warrants special attention among this population due to its long-term implications that may impair social, individual, and vocational functioning, factors that are essential for survival, productivity, and resettlement (Poole, Hedt-Gauthier, Liao, Raymond, & Bärnighausen, 2018; Ventevogel, Van, Schilperoord, & Saxena, 2015). In one meta-analysis that included 24,051 refugees from multiple nationalities pooled from international studies, 44% were found to have symptoms of depression (Lindert, Ehrenstein, Priebe, Mielck, & Brähler, 2009). Despite certain limitations of that review, such as heterogeneity of the included samples, this finding mirrors others in the literature addressing Syrian refugees in Arab settings (Doocy, Sirois, Tileva, Storey, & Burnham, 2013; Jefee-Bahloul, Barkil-Oteo, Pless-Mulloli, & Fouad, 2015; Llosa et al., 2014; Naja, Aoun, El Khoury, Abdallah, & Haddad, 2016). Furthermore, previous reports from the literature assessing prevalence rates of depression among Syrian refugees in developed and developing countries have shown disparities in the findings. Depression prevalence rates were reportedly lower in developed countries compared to developing countries, which could be attributed to the limited capacities of the latter to cope with the needs of these vulnerable populations. In Germany, depression was detected in close to 14.5% of a Syrian refugee sample (Georgiadou et al., 2018), as opposed to 37.4% in Turkey (Acarturk et al., 2018), and 43% in Lebanon (Naja et al., 2016).

Previous research suggests that despite the harsh conditions that Syrian refugees often experience, some key post-displacement variables may act as protective factors, may buffer the severity and incidence of mental health conditions, and may contribute to posttraumatic growth (Georgiadou et al., 2018; Taher & Allan, 2020). For instance, obtaining a visa or residence permission, residing in acceptable living conditions, receiving financial support, and having access to social and healthcare services, among others, have contributed to better mental health outcomes (Georgiadou et al., 2018). Rightfully so, findings have confirmed that besides the existing acute and chronic stressors, the mental health of

refugees largely depends on the social, economic, and cultural environments associated with their pre and post-displacement experiences (Porter & Haslam, 2005). However, the status of Syrian refugees in Lebanon is far from being ideal, with potential protective factors being compromised and minimally available (Kerbage et al., 2020). As an example, Syrian refugees have restricted rights in Lebanon, which limit their access to proper healthcare, education, and employment opportunities, due to the lack of a clearly defined legal and administrative framework under which they can operate (Blanchet, Fouad, & Pherali, 2016; Kerbage et al., 2020). Such systemic precariousness excludes potential opportunities for long-term integration, and places Syrian refugees in Lebanon at increased risk of developing mental health problems (Jayawickreme et al., 2017; Killikelly, Bauer, & Maercker, 2018). In addition to that, Syrian refugees lack basic needs such as food, water, and shelter. Their acculturation is also compromised, as they tend to experience discrimination resulting from the strained Lebanese-Syrian relations due to host community fatigue with their protracted presence, largely due to job competition and exhaustion of resources and services (UNHCR, 2019). This discrimination is also manifested as part of the larger socio-political climate in which continuous pressures are being exerted on Syrian refugees that threaten their physical, financial, and social security (Kerbage et al., 2020; Mourtada, Schlecht, & Dejong, 2017; Sim, Bowes, & Gardner, 2019).

Finally, the lack of sustained funding for mental health services, the fragmented mental healthcare system, and the scarcity of research make it extremely difficult to understand and respond to the psychosocial needs of refugees. Syrian refugees, being a high-risk group, have unique psychosocial needs that should be clearly addressed by mental health workers, based on evidence-driven and culturally-sensitive findings. That said, concerted efforts have been made by the National Mental Health Program (NMHP) at the Ministry of Public Health (MoPH) in Lebanon in collaboration with other healthcare and humanitarian actors to address this problem (Chammay, Kheir, & Alaouie, 2013; El Chammay & Ammar, 2014; El Chammay, Karam, & Ammar, 2016; E. Karam et al., 2016). Since the inception of the Mental Health and Substance Use Strategy for Lebanon 2015–2020, the MoPH has worked on integrating mental health services into the primary healthcare centres (PHCs) by training healthcare workers on the Mental Health Gap Action Program (mhGAP) to enhance access to mental health care (MoPH, 2015). In addition, the MoPH established the Mental Health and Psychosocial Support Task Force (MHPSS-TF) in collaboration with the World Health Organization (WHO) and the UNICEF to coordinate the work of over 62 actors on the mental health and psychosocial support within the Syrian crisis response in Lebanon (E. Karam et al., 2016). This has increased the efficiency and effectiveness of efforts targeting this problem.

In this context and despite the established initiatives, to our knowledge, there are limited large-scale studies on the prevalence of depression and its correlates among adult Syrian refugees in the Middle East. In fact, despite the urgency of the crisis, according to a recent systematic review, only six studies emanating from a conflict-affected low-to middle-income country were conducted in the Middle East to assess the prevalence rates of mental health disorders among refugees (Morina, Akhtar, Barth, & Schnyder, 2018). Clearly, there is an immense need for further research on the mental health of Syrian

refugees in this region to better understand the associated risk factors, and to support the development and implementation of global mental health policies addressing this population (Morina et al., 2018).

The present study aims to examine the prevalence rates of depression symptoms and their sociodemographic and clinical correlates among Syrian refugees in Lebanon. This study also aims to provide researchers, policy makers, and practitioners with a comprehensive understanding of depression among migrating populations, which would constitute a foundational base for future interventions and related programs and policies.

## **2. Methods**

### ***2.1 Design & Population***

Our study is a secondary analysis of de-identified data from the “Sijilli” (Electronic Health Records (EHR) for Refugees) database (Saleh, El Arnaout, Faulkner, & Sayegh, 2019). The Sijilli database includes data on 10,082 Syrian refugees in Lebanon, collected between July 2018 and January 2020 through primary field-based data collection conducted by the Global Health Institute at the American University of Beirut in partnership with Epic Systems Corporation. Data collection took place in different informal tented settlements for refugees across Lebanon, covering the Bekaa, North Lebanon, Beirut/Mount Lebanon, and South Lebanon areas. The sample size in each of these locations was proportionate to the overall Syrian refugee population residing in the latter based on UNHCR data (UNHCR, 2020) and includes 3565 refugee records (35.4%) from Bekaa, 2657 refugee records (26.4%) from North Lebanon, 2146 refugee records (21.3%) from Beirut, and 1714 refugee records (17.0%) from South Lebanon. The Sijilli database includes records of Syrian refugees of all ages, and covers 7 sections: socio-demographic information (e.g. age, gender, Syrian governorate of origin, location of the settlement, and year of migration to Lebanon), social and lifestyle habits (e.g smoking, alcohol drinking, and physical exercise), medical and surgical history, OBGYN conditions, medication use, vaccination history, and mental health screening. The mental health screening was completed through the Patient Health Questionnaire-9 (PHQ-9). Any mental health disorder reported by refugees was noted right after PHQ-9 administration. In this study, we only analysed the data of adult Syrian refugees who were 18 years of age or above (n=3255).

### ***2.2 Measures***

From the collected data, we examined sociodemographic variables of age, gender, marital status, country of origin, move date, location of settlement, and current occupation, and clinical variables of tobacco and alcohol use, medical conditions such as diabetes, cardiovascular diseases, neurological conditions, coronary artery diseases, use of psychiatric medication, and mental health conditions. Symptoms of depression were assessed in two phases using sequential methodology, which included administering the PHQ-2 followed by the PHQ-9 for those who screen positive on the former. This method has been widely used and is especially recommended for efficient data collection in conflict settings such as informal tented settlements (Poole et al., 2020).

The PHQ-9 includes 9 items rated on 4-point Likert ranging from 0 to 3, and yields a total score ranging from 0 to 27. The PHQ-9 score may be used as a categorical outcome of no, mild, moderate, moderately severe, and severe symptoms of depression, or may be used as a continuous score (Kroenke, Spitzer, & Williams, 2001). This measure screens for symptoms of depression experienced within the last 2 weeks and has previously shown evidence of validity, reliability, and unidimensionality (Sawaya, Atoui, Hamadeh, Zeinoun, & Nahas, 2016). In the present study, the PHQ-9 has shown very good reliability, with an alpha coefficient of 0.856.

### ***2.3 Analysis***

All collected data were coded and exported to SPSS v26. Descriptive statistics for sample characteristics were computed for adults using frequencies and percentages for categorical data. Internal consistency of the PHQ-9 was testing using Cronbach alpha. Participants who screened positive on the PHQ-2 and PHQ-9 were selected for further analysis. PHQ-9 score was categorized into no symptoms (0-4), mild (5-9), moderate (10-14), moderately severe (15-19), and severe (20-27). PHQ-9 categories and average scores, as well as individual PHQ-9 items were summarized by gender and tested for statistical difference using the Pearson's Chi-Square and the independent t-test. Univariate and multivariate logistic regression models were computed to determine the association of the PHQ-9 categories (mild and lower vs moderate to severe) with the sample characteristics. Coefficients and standard errors were exponentiated to produce odds ratios and 95% confidence intervals. All analyses were run at the 0.05 statistical significance level.

## **3. Results**

### ***3.1 Participants***

A total of  $n = 3255$  adult Syrian refugees were included in this study, and their characteristics are presented in Table 1. The mean age was 36.35 with a standard deviation of 13.87. Most of the participants were women (67.1%), married (78.4%), had moved to Lebanon between 2012 and 2015 (62.6%), 3.2 Prevalence and Distribution of Depression Symptoms originating from Hama governorate in Syria (18.9%), currently residing in the Bekaa governorate in Lebanon (32.6%), and unemployed (74.6%). The majority of participants reported never using tobacco (67.6%) and alcohol (99.5%), and only 1.2% reported using psychiatric medication such as antidepressants, antipsychotics, and anxiolytics. The most commonly reported medical condition was hypertension (10%), and the presence of any mental health condition was reported among only 2.1% of the study population.

### **3.2 Prevalence and Distribution of Depression Symptoms**

Of those n = 3255 adults, almost a quarter (n = 546) screened positive on the PHQ-9, indicating a 25% probable prevalence of MDD in the total population. Over half of the sample 51.6% (n = 1678) completed the full PHQ-9 and were subsequently included in the analysis. The remaining half (n = 1464) were excluded for screening negative on the PHQ-2. More than half (57.3%) of those who completed the PHQ-9 showed no or mild depression symptom severity, however, the rest (42.7%) showed moderate to severe symptom severity. The highest reported symptom severity was for “*feeling little interest and pleasure in doing things that used to be enjoyable*”, “*feeling down and depressed on most days*”, and “*having little energy to complete daily tasks*”. Whereas the least reported symptoms were for “*moving or speaking very slowly*”, and “*having suicidal thoughts*”.

Women scored significantly higher than men on the total PHQ-9 (p = 0.003) and on several of its items, such as having low energy (p < 0.001), feeling bad (p = 0.036), having concentration difficulties (p = 0.06), and experiencing suicidal thoughts (p = 0.001). In addition, results showed that depression symptoms affected women’s personal, vocational, and social functions significantly more than compared to men (p = 0.001).

### ***3.3 Sociodemographic and Clinical Correlates of Depression Symptoms***

Based on the results of the first regression model at the bivariate level, being of older age (OR 1.01, 95% CI 1.00-1.02), a woman (OR 1.39, 95% CI 1.12–1.74), divorced/separated (OR 3.75, 95% CI 1.80–7.85), on psychiatric medication (OR 2.54, 95% CI 1.07–6.04), having hypertension (OR 1.37, 95% CI 1.02–1.83) or any nervous-system related disorder (OR 1.82, 95% CI 1.24–2.66), or mental health condition (OR 5.20, 95% CI 2.37–11.42) significantly increased the odds for showing more severe symptoms of depression. There was also a trend for a longer period of stay in Lebanon, which was found to increase the odds of showing more severe symptoms of depression. On the other hand, informal tented settlement location, current occupation, tobacco and alcohol use, and having diabetes or CVDs showed no statistically significant association with symptoms of depression.

At the multivariate level of analysis, comparable results were obtained, whereby being  $\geq 45$  of age (OR 1.70, 95% CI 1.22–2.36), a woman (OR 1.35, 95% CI 1.08–1.70), divorced/separated (OR 3.32, 95% CI

1.57–7.01), reporting a neurological disorder (OR 1.77, 95% CI 1.20–2.62) or a mental health condition (OR 5.30, 95% CI 2.40-11.67) significantly increased the odds of screening positive for MDD. However, unlike the bivariate model, being on psychiatric medication and presenting with hypertension were not significantly associated with the increased odds of depression severity symptoms.

## 4. Discussion

To our knowledge, this is one of the very few regional, and the only national large-scale study addressing the mental health of a representative sample of adult Syrian refugees in Lebanon and is therefore a valuable contribution to the literature. In the present study, we report on the prevalence of depression symptoms, which represent one of the most common and debilitating mental health disorders among Syrian refugees, and we explore their sociodemographic and clinical correlates.

As expected, the prevalence of depression symptoms among the study population was high, with an estimated one in four refugees meeting criteria for MDD. Positive PHQ-9 screening and consequently, probable MDD, was detected in 25% of the study population, which is considerably higher than depression rates (9.9%) previously reported among the general population in Lebanon (E. G. Karam et al., 2008). Our findings contrast a previous study that used the same depression measure on Syrian refugees in Germany, and in which only 14% of their sample screened positive for MDD (Georgiadou et al., 2018). One of the main findings of that study was that post-migration conditions and future positive prospects in host countries may be protective against mental health disorders among these populations (Georgiadou et al., 2018). Indeed, this could explain the discrepancy between their findings and ours, considering that post-migration factors in Lebanon are poor and may ultimately present important risk factors instead of being protective against mental health disorders (Kerbage et al., 2020).

In Lebanon, many post-migration variables present important obstacles towards adequate health and survival. For example, the high prevalence rates of depression symptoms could be attributed to numerous external factors beyond their exposure to traumatic events, such as the difficult conditions in which Syrian refugees live, the limited opportunities for development, and the many challenges associated with their social integration and acculturation (Kerbage et al., 2020). Additionally, the constant internal and regional socioeconomic and political conflicts promote little hope for refugees to settle in a stable context unless they travel to more developed countries, which is a solution Syrian refugees commonly request to overcome their documented adverse living conditions (Kerbage et al., 2020). The existing economic difficulties in Lebanon, which are now exponentially compounded by the fall of Lebanese pound (Youssef, 2020), and by the colossal explosion that devastated the capital Beirut in August 2020 (Tharoor, 2020), may place Syrian refugees under further instability and vulnerability. With that said, the situation is currently expected to be worse in terms of mental health outcomes, considering the COVID-19 pandemic, which has restricted mobility, tremendously challenged the attainment of basic survival needs, induced added stress, and further limited opportunities for work and social interactions (Whaibeh, Mahmoud, & Naal, 2020).

In response to the Syrian crisis, the MoPH in collaboration with the Ministry of Social Affairs and with local and international non-governmental organizations (NGOs) have been providing free-of-charge primary healthcare services, including mental health services, for UNHCR-registered Syrian refugees. Yet, due to limited financial capacities, these efforts have been reportedly unable to meet the increasing needs of these vulnerable populations (Masri & Srour, 2014; Noubani et al., 2020). The situation is even worse for unregistered refugees who have restricted capacities to receive the appropriate healthcare support (Masri & Srour, 2014). Despite these efforts, the rates of depression remain high, as indicated by our findings. Although mental health services and psychosocial interventions may induce relief of depression severity over the short-term, long-term improvements may require complementary macro-level changes in the living conditions of refugees, their legal status, and the need to foster positive future prospects.

It is also possible that mental health services are not reaching enough refugees. Notwithstanding the value of the provided services, Syrian refugees cite many barriers to seeking mental health services in Lebanon, including lack of trust in and limited knowledge of available services, limited mental health literacy and perceived need for treatment, lack of services especially in rural areas, associated difficulties in commuting, financial barriers and lack of mental health coverage, and social stigma which may impede refugees seeking healthcare fearing of shame and discrimination (Noubani et al., 2020). Furthermore, due to pervasive cultural beliefs, Syrian refugees tend to seek religious healers as a first line of treatment for mental illness given their perceived cultural appropriateness and their reduced association with social stigma when compared to mental health professionals (Al Laham et al., 2020).

Despite high depression rates in our sample, our findings are favourable in comparison to the last study that evaluated the prevalence of depression among adult Syrian refugees in Lebanon 5 years ago, in which a depression prevalence rate of 43.9% was reported (Naja et al., 2016). Although some important limitations may prohibit this comparison, such as their reliance on a clinical diagnosis as opposed to

using a screening instrument, and their smaller sample size ( $n = 310$ ) (Naja et al., 2016), our findings may point towards an overall improvement. However, this could also be a result of the different sample characteristics, considering that Naja et al (2016)'s study represented refugees seeking social and healthcare services from two non-governmental organizations, whereas ours included a randomly selected representative sample of participants from the general population of Syrian refugees across Lebanon; under these different contexts, our sample would be expected to score lower on depression.

In terms of its correlates, our findings show that age, gender, and marital status are strongly associated with an increased risk for MDD. We found that older age is associated with higher risk of depression, which contrasts previous findings showing an inverse relationship (Georgiadou et al., 2018), or no correlation (Naja et al., 2016; Poole et al., 2018) between these variables. In specific, individuals over 45 years of age are at highest risk of developing depression, and this may be a result of several contributing factors. From a social perspective, older individuals in the Arab region are regarded as pillars of their families, and they tend to hold leadership roles in their communities (Bazzi & Chemali, 2016; Chemali, Borba, Johnson, Khair, & Fricchione, 2018). Previous research suggests that as a result of the war, this community role may be disrupted, impacting familial connectedness and social ties, and bringing along feelings of isolation and inadequacy (Chemali et al., 2018). From a clinical perspective, older individuals often have pre-existing and chronic conditions which may warrant further medical attention. In this regard, unmet healthcare needs due to the limited resources in these communities may further aggravate their mental health conditions and general well-being. Finally, comorbidities between cognitive disorders and depression may be more pronounced and severe among this age group, which may impact their well-being and overall functionality (Adams & Moon, 2009).

In terms of gender differences, previous research consistently reported higher prevalence rates of depression among women compared to men across studies among the general population, and this is also true of research among Syrian refugees (Georgiadou et al., 2018; Poole et al., 2018) congruent with our findings. Although some of the same justifications that have been previously cited in the literature may still be used to explain these gender-based variations, other explanations that are specific to Syrian refugees in Lebanon should be considered. For example, women in refugee settings tend to be subjected to early and forced marriage and bear family responsibilities at an early age, in addition to being exposed to sexual harassment and violence in the household and community at large (Noubani et al., 2020), all of which are potential stressors that increase the risk of developing MDD. Also, these women allude to child rearing and associated responsibilities as important sources of stress and anxiety, especially when considering their worries about the discrimination and bullying their children may face in schools in Lebanon (Noubani et al., 2020). Additionally, upon further scrutiny, and although the severity of depression symptoms was comparable among both genders, our findings indicate that women were significantly more likely to report feeling down, having lower energy, and having more suicidal thoughts compared to men, which is consistent with previous findings (Kim et al., 2015). Women were also more likely to report having their level of function in social, vocational, and self-care areas adversely affected by depression symptoms compared to men.

The association between marital status and depression has been previously examined among Syrian refugees, whereby being married was found to be protective against depression in one study, potentially due to its association with social support (Poole et al., 2018), and where no relationship was found in others (Acarturk et al., 2018; Georgiadou et al., 2018; Naja et al., 2016). In our study, being divorced or separated increased the odds of having depression, but this was not the case for being single or widowed. This means that the experience of going through a divorce or separation in this community could place individuals at higher risk of having depression than if they were single or had lost their spouse.

On the other hand, several variables were found not to be related to depression, most importantly the location of the informal tented settlement and the period of stay in Lebanon. It is possible that the properties of the four examined informal tented settlements for refugees in Lebanon entail similar living conditions that are below the appropriate standards and share similarity in terms of the availability of support and healthcare services, which translate into poor mental health among their residents. As for the period of stay in Lebanon, although previous studies suggested that a longer period of stay is associated with higher risk of depression (Poole et al., 2018), in our study we only found a non-statistically significant trend confirming this association at the bivariate level; however, no association was observed at the multivariate level. These findings suggest that the period of stay in Lebanon is not correlated with the risk of developing depression, given that the mental health of Syrian refugees may be equally compromised among newcomers and long-term residents. That said, arriving in Lebanon before and after the breakout of the Syrian war in 2011 was accounted for in the study analysis, and no significant differences in depression scores were observed.

In terms of the clinical characteristics, we found that reporting a neurological condition or a history of mental illness increased the risk of depression, presumably because mental illness is directly related to depression symptoms, and neurological conditions are frequently comorbid with depression (Bulloch et al., 2015). On the other hand, diabetes, CVDs and coronary artery diseases were not found to be risk factors for depression, although these have been associated with depression in previous studies (Elderon & Whooley, 2013; Mezuk, Eaton, Albrecht, & Golden, 2008). Similarly, although reporting hypertension and the use of psychiatric medication have shown a statistically significant association with depression at the bivariate level of analysis, this was not replicated at the multivariate level. This means that unlike neurological conditions, non-communicable diseases may not be significant risk factors for developing depression among Syrian refugees in Lebanon. Possibly, these associations might be clouded by the overall high rates of depression in the study population.

## **5. Recommendations & Implications**

Our findings indicate that depression prevalence rate among Syrian refugees in Lebanon is high. In light of this, an increase in screening efforts and referral mechanisms to PHCs and other health facilities is highly needed to improve access to mental health services and to reduce depression rates. According to a recent national facility assessment, almost 32% of PHCs in Lebanon are currently delivering mental

health services following the mhGAP training, and almost 50% of them cover rural areas (Hemadeh, Kdouh, Hammoud, Jaber, & Khalek, 2020), where most refugees reside. The integration of telemental health services into PHCs, community-based organizations, and other healthcare facilities that could be accessed by refugees may be a suitable option to enhance the reach of these services (N Almoshmosh, Jefee-Bahloul, Abdal- lah, & Barkil-Oteo, 2020; Naal, Whaibeh, & Mahmoud, 2020). Telemental health services have strong potential in overcoming traditional barriers to mental health service use such as transportation challenges, unequal distribution of specialists among others, and may enhance access to services (Naal et al., 2020). Importantly, considering the mobility restrictions brought forth by the COVID-19, telemental health adheres to the social distancing requirements, and enables access to mental health services for remote and underserved populations (Whaibeh et al., 2020). PHCs in Lebanon are usually equipped with the minimally required technological hardware and software needed for that, they tend to have minimally available specialized mental health care services, and their catchment areas tend to reach rural and underserved populations (Hemadeh et al., 2020). To that end, special attention should be given to high-risk groups such as older adults, women, and divorced/separated individuals, particularly those with a history of neurological or mental health conditions. More importantly, using a culturally-sensitive approach, efforts to combat social stigma and improve mental health literacy in these communities are necessary to encourage treatment seeking when available. For example, one recent qualitative study suggested that collaborations between mental health professionals and community religious healers may be a key factor to creating pathways for referrals to mental health services (Al Laham et al., 2020). Additionally, it is also important to provide minimally required and essential resources for survival, in parallel as a complement to the existing mental health services. In this regard, different aids that improve the living conditions and the quality of life for Syrian refugees are crucial, especially those that have been consistently identified as key protective factors. For example, providing options to 1) improve the financial situation in order for them to be able to meet their basic survival needs, 2) facilitate interactions with host communities and reduce tensions, and 3) improve the legal status of refugees, which help them benefit from the available services.

## 6. Limitations

Some limitations should be considered in light of our findings. First, it is important to note that the study population is not entirely homogeneous because it included individuals who came before and after the breakout of the Syrian war in 2011, which implies different levels of exposure to war trauma.

Nevertheless, we accounted for this in our analysis by comparing depression symptoms between both groups whereby no significant differences in symptom severity were observed. Second, biases such as social desirability may have influenced the collected data (e.g. symptoms of depression, alcohol use, employment etc.) since participants were administered the questionnaire through in-person interviews rather than by self-reported means, given the high levels of reported illiteracy in informal tented settlements. Third, pre-and post- migration data such as legal status, household and living conditions, and the quality of healthcare provision among others were not collected, which could otherwise have provided a clearer association between migration status and depression. Lastly, reliance on self-reported

data rather than official diagnostic reports may have resulted in under- or overestimation of the reported health conditions.

## 7. Conclusion

Mental health is of growing importance in refugee populations due to the increased vulnerability of these populations to mental health disorders. Our study findings revealed high rates of depression symptoms among the study population, with one in four refugees meeting criteria for probable MDD. Furthermore, we found an association between potential risk factors such as, being of older age, a woman, divorced/separated, having a neurological condition or a history of mental illness and the increased odds of having depression symptoms. Our findings bear important public health and clinical implications on refugee health, and call for the enhancement of screening efforts, the need to improve access and referral to mental health services, and the importance of improving post-migration factors such as those related to living conditions, acculturation, and legal status.

## Declarations

## **Acknowledgement:**

We wish to thank the following NGOs that facilitated access to the refugees across Lebanon to complete data collection of the Sijilli EHR: Malaak, Makhzoumi Foundation, and Beyond Association. We wish to also thank the volunteer health professionals who were involved in data collection including Dr. Lara Nahouli, Dr. Ghaidaa El Saddik, Mr. Mohamad Jamal Obeid, Mr. Abdul Ghani Abou Koura, Mr. Mohamad Najdi, and Mr. Nader Husseini.

## **Authors' Contributions:**

The study was designed and conceptualized by HN, NEA, DN, and SS. HN wrote the first draft, and contributed to data analysis and final revisions. NEA coordinated the overall project, contributed to writing the methodology, and edited the manuscript. DN contributed to data analysis, review, and editing of the manuscript. LA performed revisions and editing of the manuscript. HD conducted full data analysis, wrote parts of the methodology section, and edited the manuscript. RH provided support for data management and data analysis and edited the draft. SS reviewed and provided critical comments on the manuscript. All authors reviewed and approved the final version.

## **Funding:**

This research did not receive any financial support.

## **Availability of the data and materials:**

The data can be made available following reasonable request to the corresponding author.

## **Ethics approval and consent to participate:**

The present study was approved by the Institutional Review Board at the American University of Beirut. Informed consent was submitted by all subjects when they were enrolled.

## **Consent for publication:**

Not applicable.
