Abstract

Background: Osteoarthritis (OA) is a multifactorial disease that commonly affects the knee. Tumor necrosis factor- α (TNF- α) is able to regulate inflammation in OA. Macrophage migration inhibitory factor (MIF) may be involved in the pathophysiology of arthritis. Platelet-rich plasma (PRP) may reduce pain associated with OA. The current study aimed to assess the possible therapeutic effects of PRP in patients with knee OA of various severities.

Methods: A prospective study was performed on 90 patients were included and categorized into mild (30 cases, moderate (30 cases) and severe (30 cases) knee OA. Three intra-articular (I.A) injections of PRP, 2 weeks a part, were received. Pain score and MRI Osteoarthritis Knee Score (MOAKS) were assessed. Serial synovial fluid cytokines assays in the form of Tumor necrosis factor- α (TNF- α) and Macrophage migration inhibitory factor (MIF), were performed using commercially available ELISA assay kits. The assays were performed pre-injection (S1), two weeks from the 1st I.A injection and two weeks from the 2nd I.A injection (S3) for all included patients.

Results: The mean values of pain score and synovial TNF- α and MIF levels were significantly higher levels (S1, pre-injection) among severe OA when compared with both mild and moderate cases, $p \leq 0.05$ for all. There were significantly lower pain score and synovial TNF- α and MIF levels at S3 in mild, moderate and severe knee OA when compared with S1 values, $p \leq 0.05$ for all. There was significant improvement in synovitis in both mild and moderate cases ($p \leq 0.05$ for both).

Conclusion: I.A injection of PRP significantly reduces the synovial fluid TNF- α and MIF levels with great therapeutic effects on both synovitis via reducing inflammatory cytokines, and bone marrow lesions mainly for mild knee OA and to a lesser extent for moderate cases.

Background

Osteoarthritis (OA) is a disease primarily affecting the knee that is defined as a progressive loss of joint function and pain from a gradual deterioration of the articular cartilage [1]. Unfortunately, it is a frequent site due to the high use and stress of the knee joint for painful conditions including OA [2].

OA was thought to be primarily a cartilage degenerative disease; however, the latest research has shown that OA is a multifactorial cause, involving numerous causative factors such as trauma, mechanical forces, inflammation, biochemical reactions, and metabolic derangements [3]. The role of inflammation is not well understood and there is an ongoing debate to determine whether the inflammatory reaction triggers changes in the OA or, rather, the inflammation is secondary to changes in the OA [3].

The tumor necrosis factor (TNF) α has been shown to be associated with the progression of osteoarthritis. It has been shown that TNF- α is capable of regulating inflammation in an osteoarthritis rat model by downregulating the signaling pathway of phosphoinositide 3-kinase / protein kinase B (PI3K / AKT) in synovial fibroblasts [4].

Macrophage migration inhibitory factor (MIF) is a pro-inflammatory cytokine produced by macrophages which may contribute to arthritis pathophysiology by promoting inflammation and angiogenesis [5].

Recently, current approaches to OA treatment have integrated the use of biologics which mediate the inflammatory process [1]. Platelet-rich plasma (PRP) is increasingly being used for its ability to influence tissue regulation due to growth factors in high platelet levels, thereby reducing OA-related pain [6, 7]. PRP is obtained after whole blood centrifugation, yielding a highly concentrated product with platelets. The α -granules within the concentrated platelet solution contain growth factors and proteins that are vital to the coagulation cascade [8]. PRP is thought to influence degeneration of cartilage by altering the autophagy in chondrocytes. Aging cartilage gradually loses its reversible quiescence and its ability to self-renew [9].

The current work aimed to use clinical and radiological scores to determine the potential therapeutic effects of PRP in patients with various severities of knee OA. In addition, serial biochemical assays of the TNF- α and MIF levels of synovial fluid and their associations with both pain and radiological scores were performed among these patients.

Materials And Methods

Study design and participants

The present prospective study was conducted on 90 patients with knee OA, recruited from the orthopedic outpatient clinics, Qena University Hospital- South Valley University- Egypt, during the period from February, 1st 2019 to January, 31st 2020. Based on radiological assessments, the included patients were categorized into three groups (mild, moderate and severe OA) according to the OA severity. Each group included 30 patients.

The exclusion criteria is as follows: polyarticular disease; knee arthroscopy in the previous year; HA or steroid IA penetration in the preceding 3 months; history of infectious disease and autoimmune disorders such as diabetes, rheumatoid arthritis, hematologic diseases (coagulopathy), serious cardiovascular diseases, infections or immunodepression; anticoagulant therapy or an anti-aggregating agent; use of non-steroidal anti-inflammatory drugs 2 weeks prior to blood sampling; and < 10 g / dL of hemoglobin [10].

Clinical assessments

Detailed medical history and thorough clinical examination from every included subject involving age, gender, weight, height, calculation of body mass index (BMI) (kg/m^2), were recorded. As regards the BMI, it is classified into: underweight (if BMI ≤ 18.5), normal weight (18.5–24.9), overweight (25-29.9), obesity class 1 (30-34.9), obesity class 2 (35-39.9), extreme obesity class 3 (≥ 40) [11]. Local examination of both knee joints and assessment of knee joint pain for the included patients was done using Visual Analog Scale (VAS) score [12]. OA diagnosis was based on visual identification of the presence of eburning on the articular surfaces of the distal femur, proximal tibia, or patella, right or left. Eburnation is a sclerotic,

ivory-like subchondral bone reaction that takes place from bone-on-bone contact at sites exposed to advanced cartilage erosion [13,14]. The VAS is a common tool that uses a 10 cm scale for pain intensity measurement, where 0 = no pain and 10 = unable to move. Pain score assessment was performed before beginning PRP therapy and two weeks after the second PRP IA injection.

Radiological assessments of severity of knee OA

MRI Osteoarthritis Knee Score (MOAKS) was used to assess the severity of knee OA [15]. In brief, for assessment of both bone marrow abnormality or patella-femoral cartilage volume (grade I (mild if the lesion involves \leq 33% of subregional volume); grade II (Moderate: if the lesion involves 33%- 66% of subregional volume), and grade III (severe: if the lesion involves $>$ 66% of subregional volume). Regarding synovitis: grade 1 (mild or small - fluid continuous in the retropatellar space); grade 2 (Moderate or medium - slight convexity of the suprapatellar bursa), and grade 3 (severe or large - evidence of capsular distension). Meniscal desintegrity score of 0–3 applied for amount of extrusion in 4 locations: medial meniscus (medial and anterior extrusion) and lateral meniscus (medial and anterior extrusion).

Biochemical workup

- A. PRP preparation: The PRP needed for IA injection has been prepared under complete aseptic conditions. In order to avoid the effect of food intake on purified PRP, on the day of injection the patients were instructed to fast for 4 hours before blood collection. Approximately 20 mL of venous blood were drawn from the antecubital vein using an aseptic technique in an effort to avoid irritation and trauma to the platelets. The blood was obtained as an anticoagulant in ten extraction tubes (2 mL each), containing sodium citrate. The tubes were then centrifuged at 2100 rpm at room temperature for 8 minutes to separate the blood in each tube into the plasma, the buffy coat and the residual red blood cells (RBCs) [10]. Using a pipette, the PRP situated just above the selectively precipitated RBCs but not including the buffy coat was carefully aspirated from each tube. In each affected joint, 10-mL PRP samples (from the 10 blood-collecting tubes) were obtained for each patient, and 5 mL were used for IA injection [11].
- B. Serial assays of synovial fluid pro-inflammatory cytokines (TNF- α and MIF): TNF- α and MIF were measured in the synovial fluid samples, using commercially available ELISA assay kits supplied by Chongqing biospes, China, Catalog No: BYEK3327-48T, and BYEK3015, respectively, using microplate ELISA reader (EMR 500, USA), according to manufacture protocol. To extract cell debris, synovial fluid samples were immediately centrifuged at 3000 rpm for 15 min, and the supernatant was aliquoted into 1-mL cryotubes and frozen at -80°C until use. The serial assays were performed to the synovial fluid samples three times. First sample (S1) was pre-injection; the second sample (S2) was two weeks from the first injection, and the third sample (S3) was two weeks from the second injection.

Procedure and timing of IA injections of PRP

The patient was put in 20 degree flexion in supine position with the knee. Under aseptic conditions, a 21-gage needle was used to inject 5 mL of PRP into the suprapatellar knee joint pouch, using a superolateral method. Local anesthetics were not used. Patients were instructed after the injection to refrain from physical exercise for at least 24 hours but no restriction was specified regarding activities of daily living. Three IA-PRP injections were administered at 2-week intervals. The same physician who was engaged in selecting and testing participants did the injections [10].

Statistical analysis

IBM SPSS Statistics v.22 was used for analysis of the data. Mean \pm SD was used for expression of quantitative data, while, number and percentage were used for qualitative data. Kolmogro-Smirnov and Shapiro-Wilk normality tests were used. Mann–Whitney U test was used when comparing between two quantitative data and one way-ANOVA was for comparison between more than two quantitative data. Post Hoc test was used for multiple comparisons between different variables. For qualitative variables, Chi-square (χ^2) and Fisher's Exact tests were used. Pearson's correlation coefficient (r): test was used for correlating data. The level of significance was considered P value \leq 0.05.

Results

Demographic and clinical characteristics of the study participants

The current study included 90 patients with knee OA (9 males (10%) and 81 (90%) females), with female: male ratio 9:1. Their mean age was 45.5 years \pm 10.6 SD with age range of 25 to of 65 years. Their mean BMI was 31.9 \pm 2.9 kg/m² with range from 23 to 37 kg/m². The mean duration of knee OA was 28.8 \pm 17.5 months with range from 3 to 60 months. According to the BMI, 7 cases (7.7%) were categorized as overweight, 69 cases (76.6%) were categorized as obesity class 1, while obesity class 2 was presented in 14 cases (15.5%).

All patients have unilateral knee OA. Regarding to the severity of OA, the included patients were categorized into three groups: 30 cases (6 males and 24 females) have mild knee OA (33.3%), 30 patients (30 females) with moderate severity (33.3%) and 30 (3 males and 27 females) cases (33.3%) have severe degree of knee OA. Regarding these groups, there were non-significant differences as regards their mean age (46.8 \pm 10.2, 46 \pm 12.3, and 43.6 \pm 10.1 years old, respectively) or BMI (31 \pm 2.4, 32.1 \pm 2.1, and 32.6 \pm 3.9, respectively) or sex, $p \geq$ 0.05 for all.

Serial synovial fluid levels of TNF- α as regards time of intra-articular PRP injection and severity of knee OA

As regards the mean values of synovial TNF- α levels (pg/mL), there were significantly higher levels (S1, pre-injection) among patients with severe OA (144.8 \pm 13.6) when compared with both mild (35.5 \pm 7.4) and moderate (97.3 \pm 31.7) cases, $p \leq$ 0.05 for all (Fig. 1A). There were significantly lower synovial TNF- α

levels two weeks after the second I.A injection of PRP (S3) in patients with mild or moderate or severe knee OA (9.3 ± 5.4 , 44.8 ± 11.5 , and 59.7 ± 3.9 , respectively) when compared with both the pre-injection synovial fluid levels (35.5 ± 7.4 , 97.3 ± 31.7 , and 144.8 ± 13.6 , respectively) and two weeks from the 1st injection (S2) levels (17.8 ± 7.5 , 64.6 ± 15.3 , and 82.4 ± 4.3 , respectively), $p \leq 0.05$ for all (**Table.1**).

Regarding to the mean values of synovial MIF levels ($\mu\text{g/L}$), there were significantly higher levels (S1, pre-injection) among patients with severe OA (315.1 ± 23.2) when compared with both mild (7.7 ± 1.5) and moderate (47.8 ± 14.9) cases, $p \leq 0.05$ for all (**Fig. 1B**). There were significantly lower synovial TNF- α levels two weeks after the second I.A injection of PRP (S3) in patients with mild or moderate or severe knee OA (1.25 ± 0.9 , 10.6 ± 2.6 , and 82.9 ± 8.2 , respectively) when compared with the pre-injection synovial fluid levels (7.7 ± 1.5 , 47.8 ± 14.9 , and 315.1 ± 23.2 , respectively) and two weeks from the 1st injection (S2) levels (4.9 ± 0.9 , 25.3 ± 7.9 , and 107.7 ± 12.3 , respectively), $p \leq 0.05$ for all (**Table.2**).

There were significantly positive correlations between the synovial fluid TNF- α and MIF levels in S1 ($r = 0.815$, $p \leq 0.05$), S2 ($r = 0.783$, $p \leq 0.05$), and S3 ($r = 0.750$, $p \leq 0.05$).

Effect of I.A injection of PRP on pain score among patients with knee osteoarthritis

There were significantly lower mean pain score values when assessed two weeks from the second I.A injection in patients with mild, moderate or severe knee OA (1.6 ± 0.5 , 2.4 ± 1.9 , and 5.1 ± 1.9 , respectively) vs. the pre-injection pain score (3.1 ± 0.9 , 5.9 ± 0.9 , and 8.7 ± 0.7 , respectively), $p \leq 0.05$ for all (**Table.3**).

Therapeutic effects of I.A injection of PRP on MOAKS in patients with knee OA

Comparing MOAKS pre-injection vs. two weeks from the 2nd I.A injection of PRP, there was significant improvement in the bone marrow lesions among patients with mild knee OA only ($p \leq 0.05$), with significant improvement in the synovitis in both patients with mild or moderate knee OA ($p \leq 0.05$ for both), (**Fig. 2A and B, Table.4**).

There were no significant improvements in both patello-femoral cartilage volume and meniscal desintegrity in various severities of knee OA, $p \leq 0.05$ for all (**Fig. 2C, Table.4**).

Correlations of pain score with serial synovial TNF- α and MIF levels

Among the included patients with knee OA, there were significantly positive correlations between pre-injection synovial fluid TNF- α levels (S1) with the pre-injection pain score (0.84 , $p \leq 0.05$), (**Fig. 3A**), and between synovial fluid TNF- α levels 2 weeks after the 2nd injection (S3) and the post-injection pain score (0.53 , $p \leq 0.05$), (**Fig. 3B**). Also, there were significantly positive correlations between pre-injection synovial fluid MIF levels (S1) with the pre-injection pain score (0.88 , $p \leq 0.05$), (**Fig. 4A**), and between synovial fluid TNF- α levels 2 weeks after the 2nd injection (S3) and the post-injection pain score (0.7 , $p \leq 0.05$), (**Fig. 4B**).

Therapeutic outcomes of the IA injection of the PRP in patients with various severities of knee OA

Comparing the therapeutic efficiency of I.A injection of PRP among patients with knee OA, there was improvement in all patients with mild knee OA (30 cases, 100%), while 15 cases (50%) with knee OA showed improvement and only 6 cases (20%) of patients with severe knee OA showed improvement regarding pain score (**Table.5**).

Discussion

Knee osteoarthritis (OA) in subjects over 50 years of age is a major cause of pain and impairment with a serious effect on physical activity and quality of life [16]. The present study evaluates the possible therapeutic effects of I.A injection of PRP in patients with knee OA using pain score, MOAKS and biochemical serial assays of synovial fluid cytokines levels in the form of TNF- α and MIF .

Obesity and overweight have long been recognized as important risk factors for OA, in particular knee OA [17]. The current study revealed female predominance with female: male ratio 9:1. Also, there was higher frequency for patients categorized as obesity class 1 followed by obesity class 2, while those categorized as overweight have the least frequency among patients with knee OA. These were corresponds with the findings of previous studies [18–23]. The cause of female predominance may be multifactorial and these involve structural variations, prior trauma, genetic and hormonal disorders, as men had significantly higher total tibial and patella cartilage volumes than women and women had a significantly higher prevalence of baseline patellar cartilage defects. Over time women showed more volume loss in the knee cartilage compared to their male counterparts [24]. The key but not only mechanism by which obesity will lead to knee OA is possibly increased mechanical loading on the joint. Knee overloading may cause synovial joint breakdown and failure of ligament and other structural supports [24].

While platelet-rich plasma (PRP) has been approved as an agent for knee osteoarthritis therapy, different studies of PRP in the OA knee have found more consistently positive results compared to hyaluronic acid, other intraarticular injections and placebo than in other musculoskeletal tissues [25, 26]. Although the causes of osteoarthritis in the knee are not fully understood, laboratory and clinical evidence suggest that inflammatory cytokines can contribute to its pathogenesis [27, 28]. The present study revealed significantly higher synovial fluid inflammatory cytokines (TNF- α and MIF) levels (S1, pre-injection) among patients with severe OA when compared with both mild and moderate cases with significantly lower synovial TNF- α and MIF levels two weeks after the second I.A injection of PRP (S3) in patients with mild or moderate or severe knee OA when compared with both the pre-injection synovial fluid levels and two weeks from the 1st injection (S2) levels. These indicate that PRP treatment for patients with knee osteoarthritis had beneficial effects in regulating inflammatory factors. Inflammatory cytokines have been documented to form a complex regulatory signal network in femoral head osteonecrosis which is mediated by different intracellular kinase signaling pathways to regulate the recruitment, stimulation and activation of autoimmune cells [29]. In accordance, Zhang et al [30] reported that MIF levels in synovial fluid were independently associated with the severity of self-reported pain in OA patients but not in serum.

Huang et al [25] reported significantly down-regulated plasma concentrations of cytokines involving TNF- α after PRP treatment in patients with knee OA.

The current study reported significantly positive correlations between the synovial fluid TNF- α and MIF levels among the included patients with knee OA. MIF is a potent pro-inflammatory cytokine that can cause the release of many inflammatory cytokines such as interferon (IFN)- γ , interleukin (IL)-1 β , 6, 8 and TNF- α by initiating an inflammatory cascade [31].

Regarding the assessments of the therapeutic effects of I.A injection of PRP on pain score and MOAKS in the included patients with knee OA, there were significantly lower mean pain score values when assessed two weeks from the second I.A injection in patients with knee OA, with significant improvement effects on synovitis and bone marrow lesions mainly for mild knee OA and to a lesser extent for moderate cases. Unfortunately, the included treated patients didn't show any significant improvements in the patella-femoral cartilage volume or meniscal disintegrity. In accordance, Burchard et al [32] suggested that intra-articular injection of PRP may improve symptoms of osteoarthritis and decrease pain in patients with knee joint osteoarthritis, independent of the level of cartilage damage quantified by the whole organ MRI scoring method. Furthermore, a study by Laudy et al [33] demonstrated that in patients with knee osteoarthritis, PRP injections resulted in decreased pain, improved function and global assessment, and changes in joint imaging.

Favorable outcome was noticed in all included patients with mild knee (100%), while it occurred in 50% of patients with moderate severity, and (20%) of patients with severe knee OA showed improvement regarding pain score. In line with our findings, Taniguchi et al [10] reported that intra-articular PRP injection is likely to be a safe treatment option for Japanese patients with mild to moderate osteoarthritis of the knee and may have pain relief for up to 6 months. While PRP therapy has controversially discussed restorative effects on the cartilage, anti-inflammatory effects, down-regulation of cytokine levels and joint homeostasis could explain favorable effects in patients with severe osteoarthritis [34, 35].

Increasing evidence shows that the over-expressed inflammatory cytokines in the inflamed joints play an important pathophysiological role in generating and maintaining OA-induced pain by acting on nociceptive nerve cells [36]. Among the included patients with knee OA, there were significantly positive correlations between synovial fluid TNF- α and MIF levels with the pain score. In consistent with our findings, Stannus et al [37] reported that TNF- α was positively linked with total knee worsening and pain.

In conclusion, the current study confirms the presence of inflammatory process involved in the pathogenesis of knee OA including involvement of some inflammatory cytokines in the form of TNF- α and MIF. Additionally, the present study confirms that among the therapeutic mechanisms of using I.A injection of PRP in patients with knee OA is the anti-inflammatory effect, where PRP may lower the synovial fluid cytokines (TNF- α and MIF) with subsequent improvement of pain and synovitis. This favorable outcome is prominently achieved in patients having mild and to a lesser extent moderate OA, thus could be established as safe adjuvant biologic therapy for such patients.

Study Limitation

Lack of long term follow up of the included patients, which could be approached in future research and relatively small sample size, were the main limitations of the study.

Tables

Table 1. Comparison of serial synovial fluid levels of TNF- α as regards time of intra-articular PRP injection in patients with knee OA

TNF- α (pg/mL, Mean \pm SD)	S1	S2	S3	P-value		
	(n =30)	(n = 30)	(n = 30)	P1	P2	P3
Mild OA	35.5 \pm 7.4	17.8 \pm 7.5	9.3 \pm 5.4	< 0.001	< 0.001	0.01
Moderate OA	97.3 \pm 31.7	64.6 \pm 15.3	44.8 \pm 11.5	0.002	< 0.001	0.048
Severe OA	144.8 \pm 13.6	82.4 \pm 4.3	59.7 \pm 3.9	< 0.001	< 0.001	< 0.001

P1= S1 vs. S2; P2= S1 vs. S3; P3= S2 vs. S1.

N.B: TNF- α : tumor necrosis factor- α ; PRP: platelet rich plasma; OA: osteoarthritis; SD: standard deviation; S1: first synovial fluid sample assay (before IA injection of PRP); S2: second synovial fluid sample assay (after 2 weeks of the 1st IA injection of PRP); S3: third synovial fluid sample assay (after 2 weeks of the 2nd IA injection of PRP).

Table 2. Comparison of serial synovial fluid levels of MIF as regards time of intra-articular PRP injection in patients with knee OA

	S1 (n = 30)	S2 (n = 30)	S3 (n = 30)	P-value		
				P1	P2	P3
MIF ($\mu\text{g/l}$, Mean \pmSD)						
Mild OA	7.7 \pm 1.5	4.9 \pm 0.9	1.25 \pm 0.9	< 0.001	< 0.001	< 0.001
Moderate OA	47.8 \pm 14.9	25.3 \pm 7.9	10.6 \pm 2.6	< 0.001	< 0.001	0.003
Severe OA	315.1 \pm 23.2	107.7 \pm 12.3	82.9 \pm 8.2	< 0.001	< 0.001	0.002

P1= S1 vs. S2; P2= S1 vs. S3; P3= S2 vs. S1.

N.B: MIF: Macrophage migration inhibitory factor; PRP: platelet rich plasma; OA: osteoarthritis; SD: standard deviation; S1: first synovial fluid sample assay (before IA injection of PRP); S2: second synovial fluid sample assay (after 2 weeks of the 1st IA injection of PRP); S3: third synovial fluid sample assay (after 2 weeks of the 2nd IA injection of PRP).

Table 3. Effect of intra-articular injection of platelet rich plasma (PRP) on pain score among patients with knee osteoarthritis (OA) of various severities

Patients groups	Pain score (Mean \pm SD)		P-value
	Pre- injection	2 weeks from the second injection	
Mild OA (n = 30)	3.1 \pm 0.9	1.6 \pm 0.5	0.001
Moderate OA (n = 30)	5.9 \pm 0.9	2.4 \pm 1.9	0.002
Severe OA (n = 30)	8.7 \pm 0.7	5.1 \pm 1.9	< 0.001

Table.4 Comparison of the therapeutic effects of I.A injection of PRP on MOAKS in patients with knee OA

Patients groups	Patello-femoral cartilage volume (Mean±SD)		P-value
	Pre- injection	2 weeks from the second I.A injection	
Mild OA (n = 30)	0.24 ±0.04	0.22±0.05	0.227
Moderate OA (n = 30)	0.55±0.10	0.55±0.10	1.0
Severe OA (n = 30)	0.71±0.08	0.70±0.08	0.677

Meniscal desintegration (Mean±SD)			
Mild OA(n = 30)	1.0±0.0	1.0±0.0	—
Moderate OA (n = 30)	2.0±0.0	2.0±0.0	—
Severe OA (n = 30)	3.0±0.0	2.1±1.4	0.280

Bone marrow abnormality (Mean±SD)			
Mild OA	0.30 ± 0.02	0.19 ± 0.07	0.001
Moderate OA	0.45 ± 0.13	0.41 ± 0.18	0.684
Severe OA	0.75 ± 0.06	0.73 ± 0.06	0.579

Synovitis (Mean±SD)			
Mild OA	0.80 ± 0.79	0.02 ± 0.01	0.0393
Moderate OA	1.80 ± 0.91	0.03 ± 0.0	0.001
Severe OA	1.81 ± 1.54	0.03 ± 0.0	0.143

N.B: I.A (intra-articular); OA (osteoarthritis); PRP (platelet-rich plasma); MRI Osteoarthritis Knee Score (MOAKS); SD: standard deviation.

Table 5. Comparison of the therapeutic outcomes of the IA injection of the PRP in patients with various severities of knee OA

		Mild OA		Moderate OA		Severe OA		P-value			
		(n = 30)		(n = 30)		(n = 30)		P1	P2	P3	
Outcome	Improved	30	100%	15	50%	6	20%	0.036	0.001	0.175	
	(No.,%)										
	Not improved	0	0%	15	50%	24	80%				
	(No.,%)										

Figures

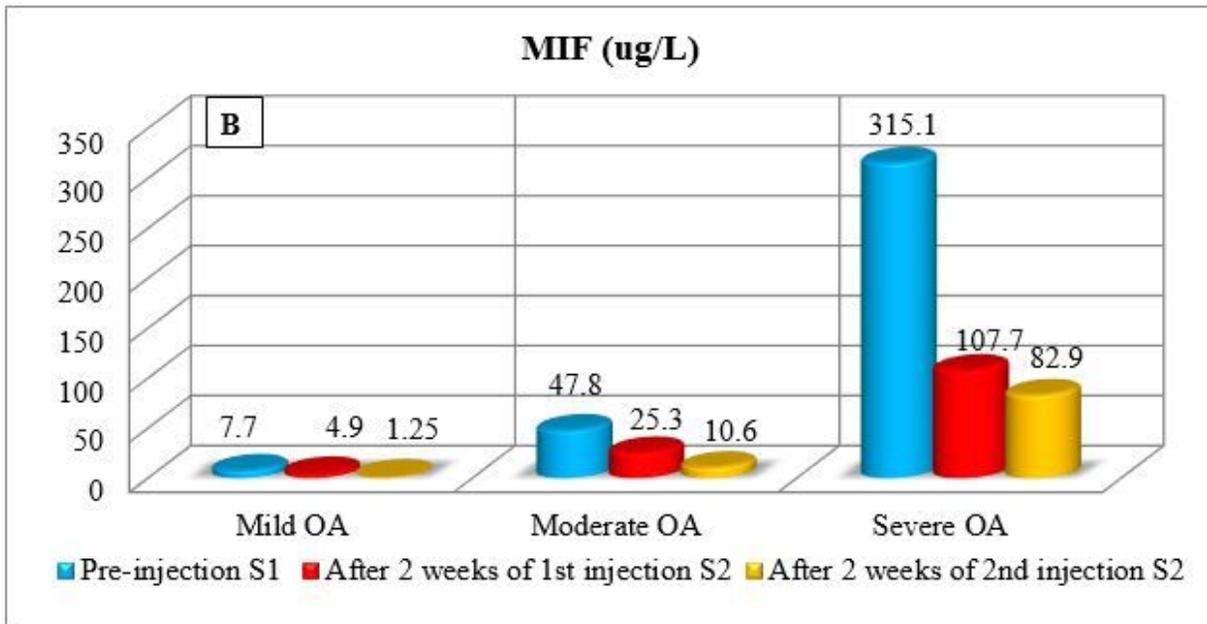

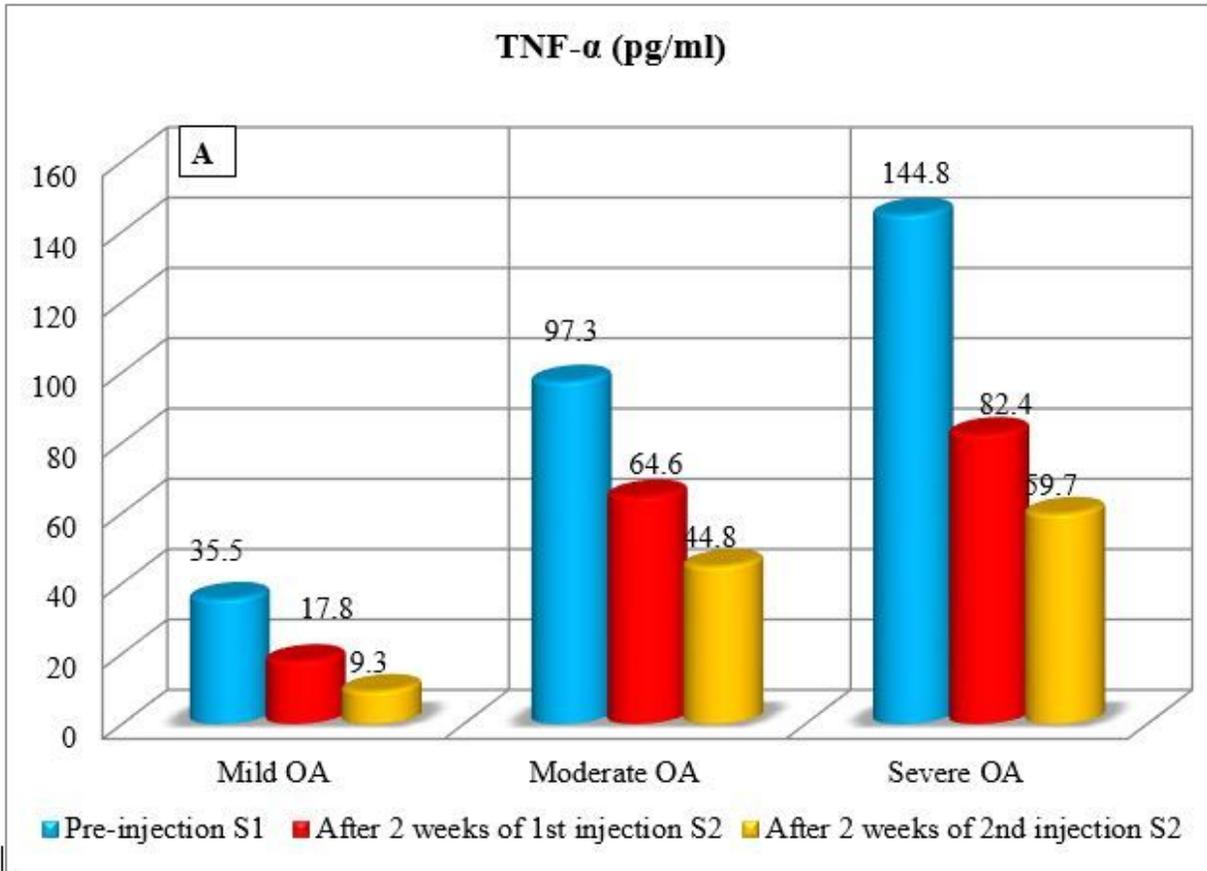

Figure 1

Comparison of serial synovial fluid levels of tumor necrosis factor (TNF) α (A) and macrophage migration inhibitory factor (MIF) (B) as regards severity of knee osteoarthritis (OA)

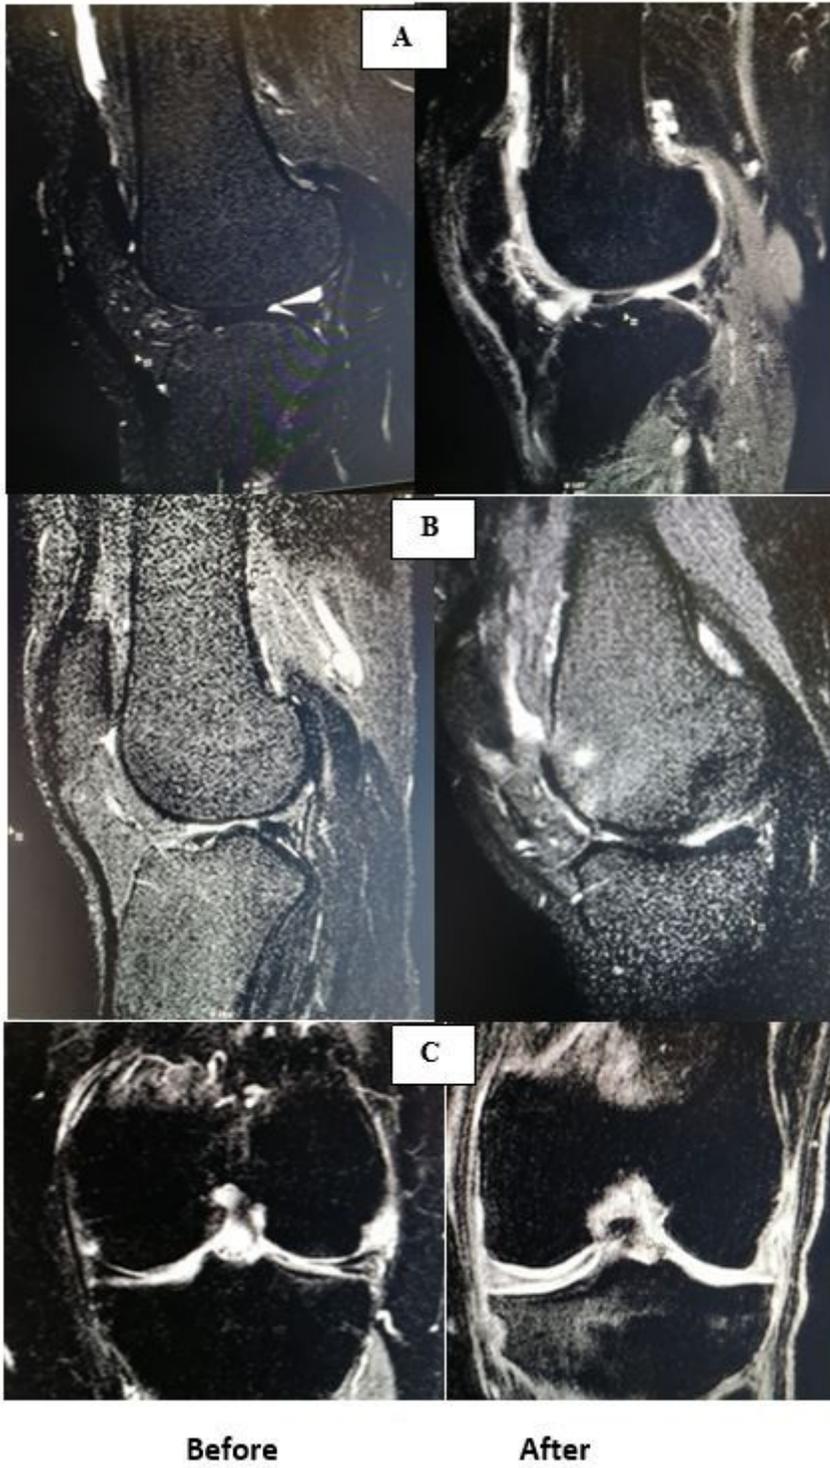

Figure 2

MRI analysis of knee joint before and after IA injection of PRP two weeks after the second injection, MRI signals showed that there were significant improvement in the synovitis (A) and bone marrow lesions (B) with no improvement in cartilage loss(C) compared with pre injection condition.

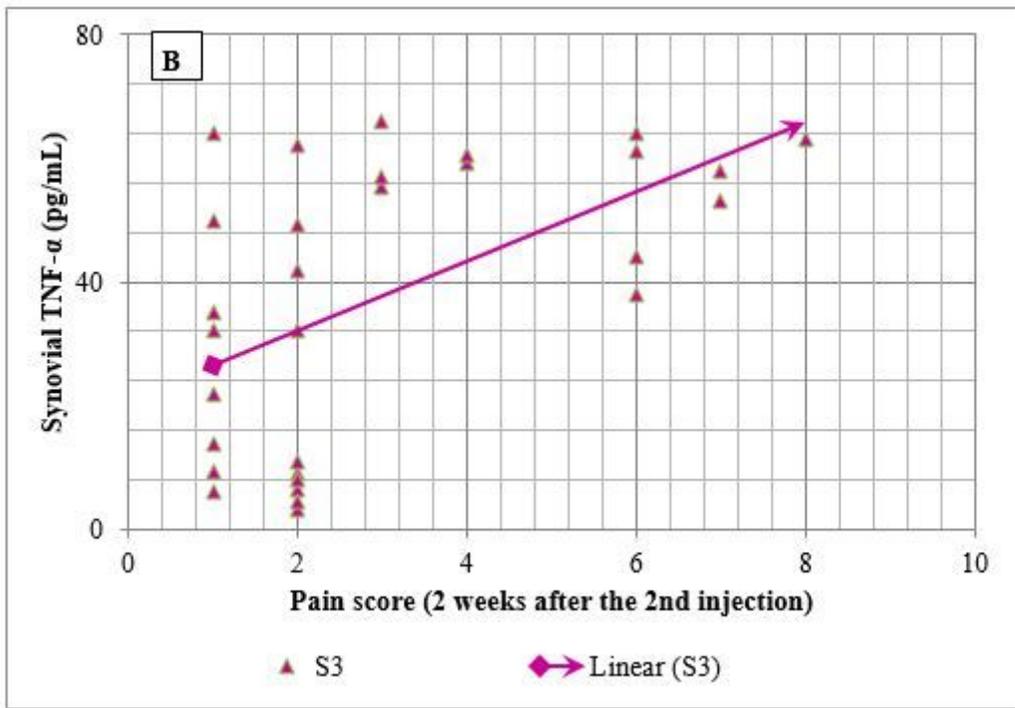

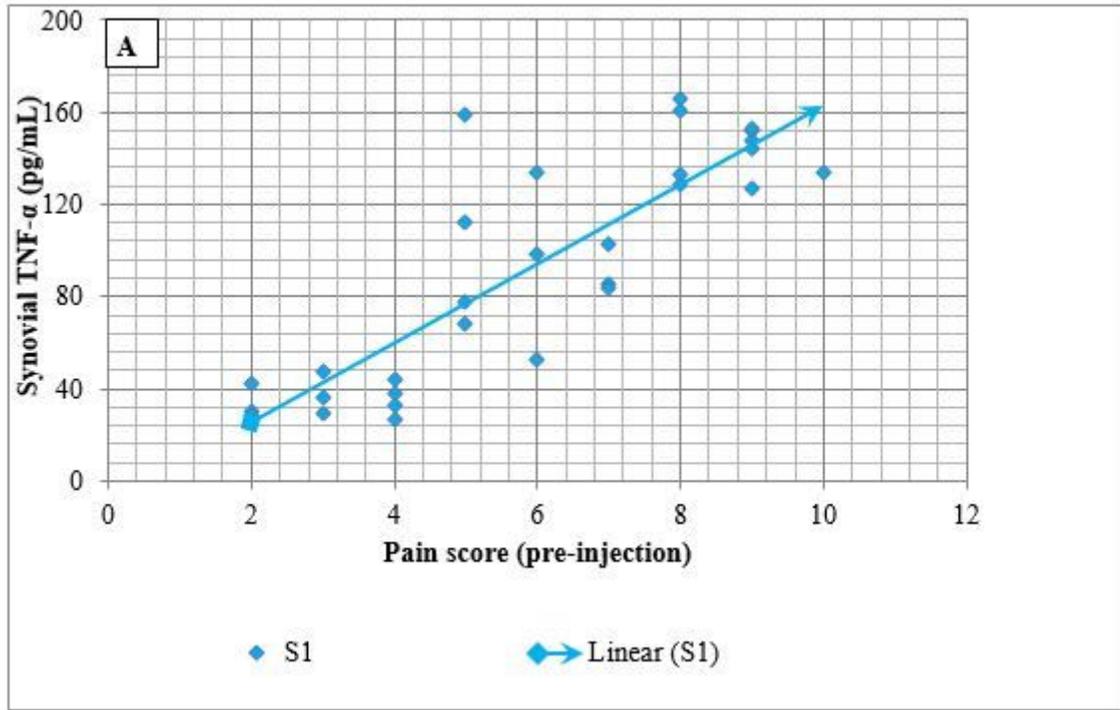

Figure 3

Correlations of pain score with serial synovial TNF- α levels among patients with knee osteoarthritis both pre-injection (A) and 2 weeks after the 2nd injection (B).

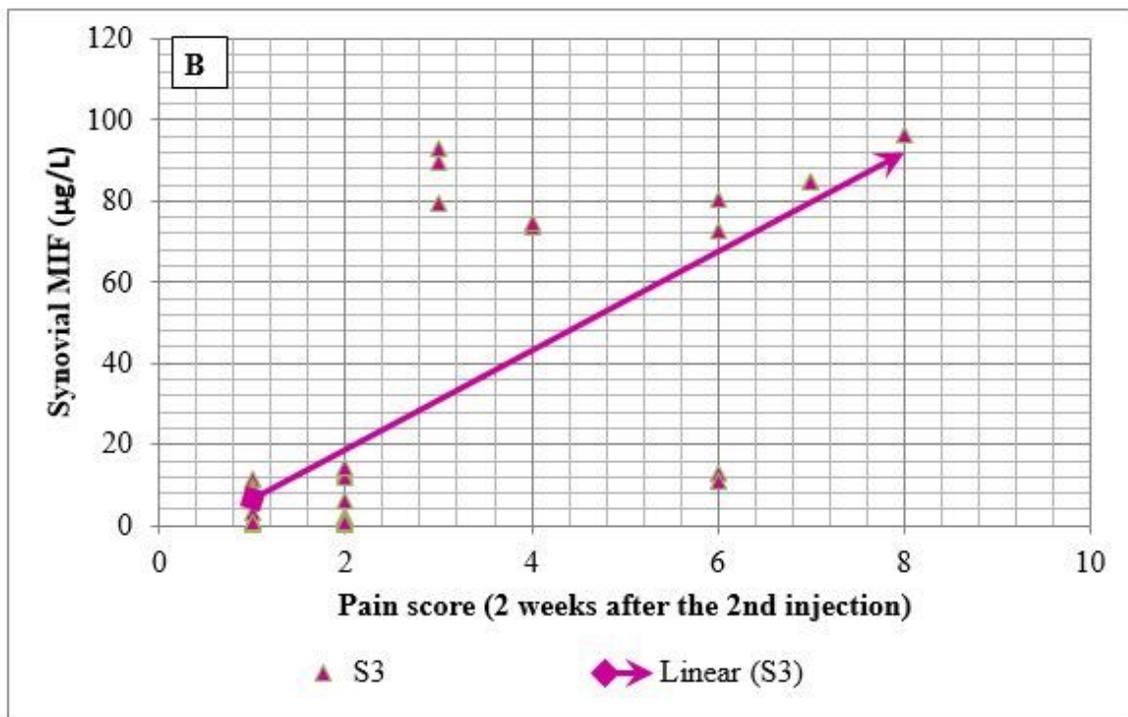

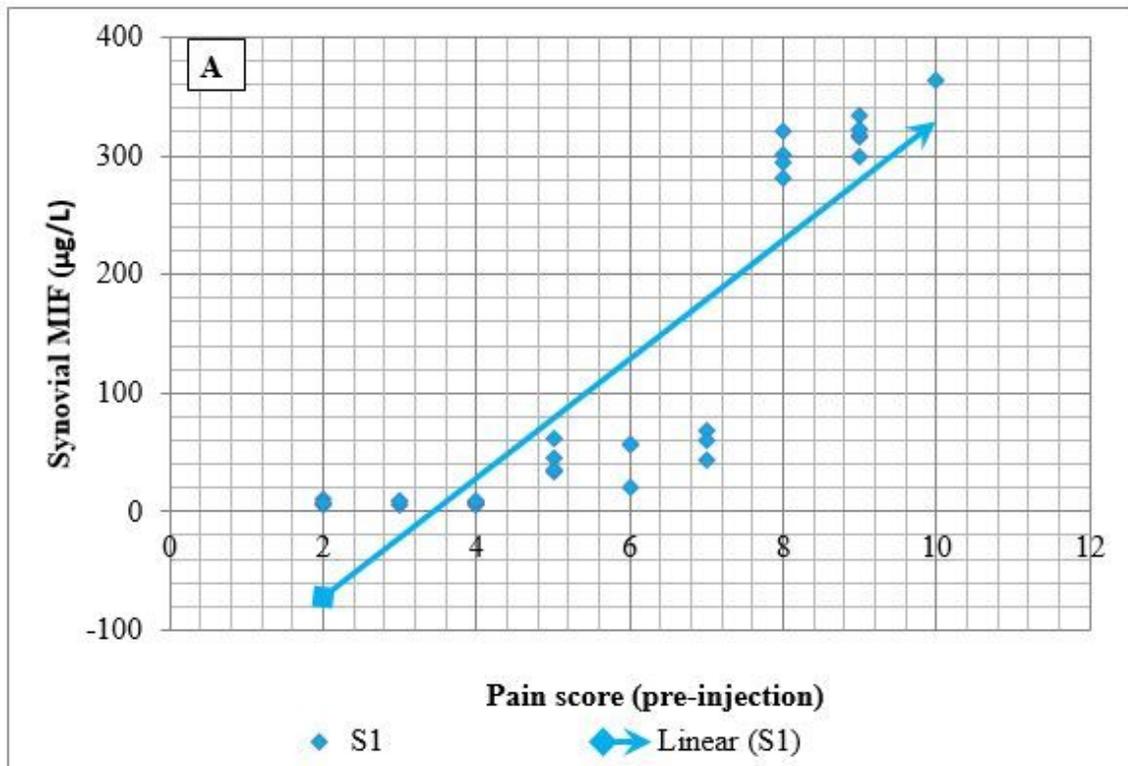

Figure 4

Correlations of pain score with serial synovial MIF levels among patients with knee osteoarthritis both pre-injection (A) and 2 weeks after the 2nd injection (B).
