# Abstract

## Background

Acute uncomplicated lower urinary tract infection (UTI) is one of the most common bacterial infections. Patients usually present with dysuria, urinary urgency, urinary frequency and suprapubic pain or tenderness. Approximately 150 million people are diagnosed with UTI each year worldwide. The high recurrence rate of lower UTI is a common problem of clinical treatment. The misuse of antibiotics has led to the emergence of a number of resistant bacterial strains. Thus, traditional Chinese medicine is considered as an alternative option for treating acute uncomplicated lower UTI. Thus, this study aims to evaluate the efficacy, safety and recurrence rate of Sanjin tablets (SJT) for the treatment of acute uncomplicated lower UTI; explore whether SJT can reduce or substitute the use of antibiotics in the treatment of acute uncomplicated lower UTI.

## Methods/Design

In this study, a randomized, double blind, double dummy, parallel control of positive drug, multicentre clinical study will be established. A total of 252 patients with acute uncomplicated lower UTI (syndrome of dampness-heat in the lower jiao) will be randomly allocated in the ratio of 1:1:1 to three groups: experimental group, control group 1 and control group 2. The experimental group receives Sanjin tablets plus levofloxacin tablets (LT) placebo; the control group 1 receives LT plus SJT placebo; and the control group 2 receives SJT plus LT on the first 5 days, SJT plus LT placebo on the last 2 days. Each group will be treated for 7 days and followed-up for 1-2 times. The primary outcome measures of effective rate and recurrence rate are symptoms. Secondary outcome measures of effective rate and recurrence rate are the urine leukocyte, bacteriology examination and safety assessment. Outcomes will be assessed at baseline and after treatment.

## Discussion

This study protocol will provide the research data of efficacy, safety and recurrence rate of SJT for the treatment of acute uncomplicated lower UTI; explore the possibility of using SJT to reduce or substitute the use of antibiotics. The results of this study will improve the rational use of drugs, especially the rational application of antibiotics. It will also enable safety evaluation from laboratory indices and adverse events, which will provide reliable evidence for clinical treatment.

## Background

Acute uncomplicated lower urinary tract infection (UTI) is one of the most common bacterial infections. Patients usually present with dysuria, urinary urgency, urinary frequency and suprapubic pain/tenderness[1]. In the United States, there are more than 7 million outpatients with UTIs and about 1

million inpatients each year[2].{!!! INVALID CITATION !!! , ;Foxman, 2003, Epidemiology of urinary tract infections: Incidence, *m* or *bty*, and economic costs} Approximately 150 million people are diagnosed with UTI each year worldwide[3]. UTI, which can cause shock and death, ranks third among all diseases that die from infection[4]. Gram-negative bacteria, especially Enterobacteriaceae, is the common cause of both community-acquired and hospital acquired UTIs[3, 5]. Many Chinese medicines that have a heat-clearing and detoxicating function have been proved to have the bacteriostasis on pathogenic microorganisms, which can inhibit or destroy the formation of toxic substances[6, 7]. In the antibacterial test against mice, it was found that Sanjin tablets have strong bacteriostasis activity[8].

Sanjin tablets have the effects of clearing heat, detoxicating, eliminating dampness and treating stranguria[9]. It is used to treat urinal urgency, frequency and burning caused by syndrome of dampness-heat in the lower jiao, which coincides with the symptoms of acute uncomplicated lower UTI. Sanjin tablets are composed of five kinds of Chinese herbal medicines: Jinyinggen (Root of Cherokee Rose), Baqia (Chinaroot Greenbrier Rhizome), Yangkaikou (Fruit of Fiverleaf Akebia), Jinshateng (Lygodii Herba) and Jixuecao (Asiatic Pennywort Herb), all of which are recorded in the Chinese Pharmacopoeia (V.2015). Jinyinggen (Root of Cherokee Rose) is acerb and neutral in nature; it can control nocturnal emission and astringent intestine. Baqia (Chinaroot Greenbrier Rhizome) is cosin and neutral in nature; it can remove rheumatism, promote blood circulation, detoxicate, relieve convulsion and calm endogenous wind. Jinshateng (Lygodii Herba) is slightly sweet and cold-natured; it can clear heat, detoxicate and remove dampness. The above three herbs are monarch drug in a prescription, which have mutual promotion effect on the function of clearing heat, removing dampness and inducing diuresis for treating stranguria. The above three medicines supplemented with Yangkaikou (Fruit of Fiverleaf Akebia) and Jixuecao (Asiatic Pennywort Herb) can enhance the effects of removing dampness and treating stranguria[10, 11].

Sanjin tablets are completely natural preparation with significant efficacy in treating UTI[12]. Previous clinical studies have indicated that Sanjin tablets can reduce the symptoms of chronic urinary tract infection and number of acute attacks; can reduce the secretory level of urinary sIL-2R, IL-6, IL-8 in patients with chronic nephropylitis[8]. Observation by electron microscope found that Sanjin tablets can make Escherichia coli flagella drop, and have good safety. A meta-analysis has demonstrated that the current evidence is insufficient to support the efficacy and safety of SJT for acute uncomplicated lower UTI due to lack of high-quality randomized controlled trials[13]. The high recurrence rate of lower UTI is a common problem of clinical treatment[14]. The misuse of antibiotics has led to the emergence of a number of resistant bacterial strains[15]. Unfortunately, the efforts to produce new antibiotics have not been sufficient to cope with the emergence of these new antibiotic-resistant (AR) strains[16]. Therefore, the objective of our study is to evaluate effectiveness, safety and recurrence rate of Sanjin tablets and explore whether Sanjin tablets can reduce or substitute the use of antibiotics for acute uncomplicated lower UTI by a rigorous randomized controlled trial.

## Method/design

## Objective and design

This is a randomized, double blind, double dummy, parallel control of positive drug, multicentre clinical study. The study will be conducted in the XiYuan Hospital, China Academy of Chinese Medical Sciences; the Longhua Hospital Shanghai University of Traditional Chinese Medicine; the Guangdong Provincial Hospital of Traditional Chinese Medicine; the Hubei Hospital of Traditional Chinese Medicine; the Affiliated hospital of Chengdu University of Traditional Chinese Medicine; the Yunnan Provincial Hospital of Traditional Chinese Medicine. Ethical clearance for the trial was obtained from ethics committee of the six hospitals. Patients with acute uncomplicated lower UTI undergo a standardized baseline evaluation before treatment comprising detailed history taking, physical examination and laboratory testing. All included patients are randomly divided into three groups: experimental group, control group 1 and control group 2. The experimental group receives SJT plus levofloxacin tablets (LT) placebo; the control group 1 receives LT plus SJT placebo; and the control group 2 receives SJT plus LT on the first 5 days, SJT plus LT placebo on the last 2 days. The efficacy and safety of the Sanjin tablets will be assessed after 7 days' treatment; the recurrence rate will be assessed at 28 days' follow-up after cured. The trial is conducted in accordance with the World Medical Association Declaration of Helsinki and Good Clinical Practice of Pharmaceutical Products[17, 18]. After a full explanation by the clinicians, written informed consent will be obtained from the included subjects before intervention[19, 20]. Strict data management and quality control will be conducted in this trial[21, 22]. This trial was registered in the Clinical Trials USA registry (registration No. NCT03658291) on 4 September 2018 and will be carried out from January 2019 to December 2019. The study design is shown in figure 1. The protocol follows the recommendations of the SPIRIT initiative [see Additional file 1] [23], and the trial results will be reported according to the latest version of the CONSORT statement [24].

## Patient and public involvement

Patients were not involved in the research question, design, conduct, outcome measures and data analysis of the study. Only medically trained clinicians carry out the patient recruitment and management in the study. The clinicians will describe the purpose, burden of the intervention, procedure and potential risks of this trial to the participants themselves or their designated representative before the recruitment. We will disseminate the results of this study to participants through patients organizations and open lectures.

## Sample size

The effective rate will be taken as the main outcome measure of the clinical trial. According to a previous study, it showed that the effective rate of Sanjin tablets was 77.14% in the treatment of simple bacterial lower urinary tract infection[25]. On the basis of a 0.9 power to detect a significant difference ( $\alpha=0.01$ , two-sided), 76 participants will be required for each group. 228 participants will be required for the three groups in a 1:1:1 ratio. Considering a 20% drop-out rate, we plan to include 252 patients in the whole trial.

# Participants and recruitment

## Diagnostic criteria of western medicine and TCM

The western medicine diagnostic criteria of acute uncomplicated lower UTI will refer to the *Guidelines for the diagnosis and treatment of urological diseases in China* (2014 ed)[26]. The TCM diagnostic criteria of acute uncomplicated lower UTI will refer to the *Clinic terminology of traditional Chinese medical diagnosis and treatment-syndromes, Internal Medicine of TCM*[27, 28, 29]. According to the characteristics and functions of Sanjin tablets, it is proposed to select the syndrome of dampness-heat in the lower jiao as the syndrome of TCM in this trial.

## Inclusion criteria

Inclusion criteria are as follows: (i) >18 and <50 years old; (ii) meet the western diagnostic criteria of acute uncomplicated lower UTI[26], the disease duration does not exceed 72 hours; (iii) bacterial culture result will be sensitive to levofloxacin (bacterial culture and clinical treatment will be conducted at the same time); (iv) the syndrome differentiation of TCM is syndrome of dampness-heat in the lower jiao; (v) did not receive antibiotic treatment within 48 hours before being selected; (vi) do not pregnant or lactating; (vii) sign the written informed consent form for the clinical trial.

## Exclusion criteria

Exclusion criteria are as follows: (i) allergic to the test drug or quinolones; (ii) there was a history of bacterial culture that was not sensitive to levofloxacin; (iii) diagnosed as complicated UTI; (iv) patients with urinary calculi or obstruction, urinary tuberculosis, renal papillary necrosis, perinephric abscess or neurogenic bladder; (v) combined with vaginitis symptoms, genital ulcers or gonorrhea; (vi) combined with severe cardiopulmonary disease, liver and kidney disease, advanced tumor and other serious or progressive disease; (vii) have a neurological or mental illness and can not cooperate; (viii) use other antibacterial drugs in combination; (ix) pregnant, lactational women or recent birth planners; (x) taking part in another clinical trial within 3 months before being selected.

## Exit criteria

Patients will leave the trial when one of the following criteria is met: (i) wrongly included; (ii) are poorly compliant or pregnant; (iii) no medication or any records of follow-up; (iv) occurrence of allergic reactions or serious adverse events; (v) participants have other complications or special physiological changes during the trial; (vi) patients have been treated with other medicines during the trial; (vii) not alleviated or the symptoms are aggravated. Participants may withdraw from the study at anytime for any reason.

# Randomization and allocation concealment

The randomization will be used for patients' allocation[30]. The randomization will be performed by an independent statistician. The random numbers are divided into three groups sequentially: experimental group, control group 1 and control group 2. Using SAS 9.1.3 statistical software PROC PLAN procedure statements, given the seed number, and randomized grouping tables will be generated for the 252 patients receiving treatment. On-site drug blinding will be carried out, and emergency unblinding procedures will be created. Blinded materials will be kept by a full-time investigator who will not participate in any part of the trial. During the course of the trial, the investigator will be able to obtain the randomized number and drug number of each patient from the designated central randomized platform.

## Blinding

This is a double-blind (with patients and clinicians blinded) and double-dummy study[31]. A two-stage blind design was used. The first stage was group A, group B, group C, and the second stage was randomly assigned to experimental group, control group 1 and control group 2 according to SAS software, without correspondence to group A, group B, group C. Treatment assignments will not be revealed until the whole process is complete. If patients have severe adverse events, clinicians will log on to the central platform to unblind the patients as an emergency and provide relevant treatment. Once the blinding is broken, the patient with this number will be withdrawn from the trial, and the clinicians will record the reasons in the CRF. To achieve blinding, all three groups will use the same kind of packaging to encase the drug or placebo. Size, colour, shape, taste, smell and packaging of the placebo are made identical to that of the corresponding medicine by adding artificial pigment.

## Interventions

All researchers are clinical doctors and receive standardized training for the diagnostic interview before the start of the trial. Levofloxacin tablets are licensed for UTI with proven curative effect and safety[32]. Therefore, levofloxacin have been selected as the active control medicine. Participants in the experimental group will receive SJT plus LT placebo orally four times a day for 7 days. Participants in the control group 1 will take LT plus SJT placebo four times a day for 7 days. Participants in the control group 2 are about to receive SJT and LT four times a day for the first 5 days, SJT plus LT placebo four times a day for the last 2 days. Patients' visits are required after 7 days' treatment. This is a placebo-controlled study; all participants receive the same number of pills with varying proportions of active drug and placebo to ensure that patients and clinicians are not aware of the allocated treatment aim. The SJT placebo is composed of 55% microcrystalline cellulose, 41% starch, 2% caramel, 1.5% silicon dioxide and 0.5% talcum powder. LT placebo is made of 56% microcrystalline cellulose, 42% starch, 1.5% silicon dioxide and 0.5% talcum powder. The SJT placebo and LT placebo are similar to the Sanjin tablets and levofloxacin tablets in size, colour, shape, taste, smell and packaging, respectively. SJT and its placebo

and LT placebo are produced by Guilin Sanjin Pharmaceutical Co., Ltd and can be preserved for 2 years. Levofloxacin tablets is provided by First Sankyo Pharmaceutical (Beijing) Co., Ltd at a dosage of 100 mg and can be preserved for 2 years. The recommended dosage of Levofloxacin tablets is 2-3 times a day, one pill at a time; hence, in order to meet the requirements of the blinding, the administration method of this medicine has been designed as described in Table 1.

## Follow-up

All included patients will be re-evaluated after 7 days' treatment follow-ups as an outpatient to assess the efficacy and safety. The patients who were cured will receive the second follow-up after 28 days to assess the recurrence rate. Patients whose symptoms worsened will receive a supply of relevant medicine and a written withdrawal schedule. Assessment of study endpoints and duration of follow-up is shown in figure 2.

## Outcome measures

### Effective rate

The effective rate will be evaluated from three dimensions: symptoms, urine leukocyte and bacteriological examination.

#### *Primary Outcome Measure*

The symptoms of acute uncomplicated lower UTI will be assessed. The assessment tools for symptoms of acute uncomplicated lower UTI are three participant self-rating scales [see Additional file 2]: criteria sheet for evaluating the severity of urinary system infection (CSESUSI); symptoms score sheet of TCM (SSST); OABSS. The CSESUSI will use scoring method to record the changes of symptoms and signs before and after treatment; focus on the record of shiver, fever, dysuria, urinal pain, urinary urgency, urinary frequency, lower abdomen distending pain, lumbago and percussion tenderness over kidney region. The SSST use scoring method to record the changes of symptoms, tongue and pulse in TCM before and after treatment. The Overactive Bladder Symptom Score (OABSS) has been found to be reliable and valid and highly responsive to treatment related fluctuations in overactive bladder symptoms. Repeating the test after an acceptable treatment interval is an effective way to assess the efficacy of a particular drug regimen on OAB symptoms[33, 34]. If the symptoms disappeared after 7 days' treatment, it indicates that the subject is cured. If these symptoms partially disappeared after 7 days' treatment, it indicates that the treatment is effective but not cured. If there was no obvious remission and the symptoms of infection persisted after 7 days' treatment, it indicates that the treatment is invalid.

#### *Secondary Outcome Measure*

(i) The urine leukocyte of 252 participants will be assessed. If the value of urine leukocyte returned to the normal value after 7 days' treatment, it indicates the subject is cured. If the value of urine leukocyte reduced but not returned to the normal value after 7 days' treatment, it indicates that the treatment is effective. If the value of urine leukocyte was still higher than normal value after 7 days, it indicates invalid treatment.

(ii) The bacteriological examination of 252 participants will be assessed. If the original infected part of the specimen did not regenerate the original infected pathogen after 7 days' treatment, it indicates the original bacteria is cleared. If the original pathogen was still cultured in the culture of the specimen from the original infection position, it indicates the original bacteria is not cleared.

### ***Criteria of comprehensive efficacy***

(i) Criteria of cured—the evaluation of clinical symptoms reached the level of cure after 7 days' treatment; the value of urine leukocyte returned to the normal value; the original infected bacteria was cleared after 7 days' treatment. The above three must be included at the same time.

(ii) Criteria of effective treatment—the clinical symptoms were alleviated but not reached the level of cure after 7 days' treatment; the value of urine leukocyte reduced but not returned to the normal value after 7 days' treatment. Anyone of both is regarded as effective.

(iii) Criteria of invalid treatment—the clinical symptoms were not alleviated after 7 days' treatment; the value of urine leukocyte was still higher than normal value after 7 days' treatment; the original infected bacteria was still cultured from the original infection position after 7 days' treatment. The above three must be included at the same time.

## **Recurrence rate**

Patients who were cured will receive the second follow-up after 28 days to assess the recurrence rate. Recurrence criteria: has "(i)", and has one of "(ii)" or "(iii)" at the same time.

### ***Primary Outcome Measure***

(i) The recurrence rate of cured subjects will be assessed by the symptoms of acute uncomplicated lower UTI. The assessment tools of recrudescence symptoms will also use the three participant self-rating scales [see Additional file 2]: criteria sheet for evaluating the severity of urinary system infection (CSESUSI); symptoms score sheet of TCM (SSST); OABSS. If the symptoms of cured subjects reappeared in the fourth week after the end of medication, it indicates the subject has relapsed.

### ***Secondary Outcome Measure***

(ii) The recurrence rate of cured subjects will be assessed by urine leukocyte. If the urine leukocyte value of cured subjects rose again in the fourth week after the end of medication, it indicates the subject has

relapsed.

(iii) The recurrence rate of cured subjects will be assessed by bacteriological examination. If the urine culture of cured subjects indicated that the original urinary tract pathogen is positive again in the fourth week after the end of medication, it indicates the subject has relapsed.

## **Safety assessments**

Safety measurements included laboratory indices and adverse events. All patients will undergo the following laboratory examination before enrollment and at the end of the clinical trial. Changes in the laboratory indices before and after the clinical trial will be compared to conducting a safety analysis. Laboratory indices are: (i) routine blood and urine testing; (ii) liver function (AST, ALT, TBIL, DBIL,  $\gamma$ -GT, ALP) and kidney function (Scr, BUN); (iii) ECG. The occurrence of any adverse events in trial participants, such as subjective discomfort of patients and abnormal laboratory results, will be recorded in the case report forms (CRF) during the whole trial process. We will withdraw patients who have severe adverse events, as it is unsafe for them to continue the trial. Meanwhile, we will give them relevant medical care and follow them up until the reaction has terminated.

## **Informed consent**

Before enrolling patients in the trial, the investigating doctor will be completely and comprehensively describe the purpose, procedure, and potential risks of this trial in writing to the patient themselves or their designated representative. Patients will be informed that they have the right to withdraw from the trial at any time. Each patient must provide written informed consent before participating in this study; this consent will be kept in the study file.

## **Quality control**

Quality assessment will be conducted in the following aspects in this trial: the progress of the trial, the qualifications of the investigators, the mastery of the program, the authenticity, accuracy and completeness of the CRF, archival preservation, program implementation, adverse events, drug preservation and storage, written informed consent, subjects compliance, and laboratory examination data. In particular, the authenticity and accuracy of the CRF, program implementation, and determination of adverse events will be strictly inspected.

## **Data management**

The patients in this trial will be recruited patients. Therefore, the original data will include the CRF, patient log card, original laboratory examination, and written informed consent. The inspector will regularly visit

all centers to conduct a data quality inspection. The authenticity and accuracy of data will be checked by original laboratory comparison, telephone follow-up with patients, and examination of the integrity, timeliness, and normalization of data. The paper form of the data will be collected after approval inspection. The researcher who is responsible for data entry will build an EpiData-based database with double-recorded data entry by two people, and consistency testing will be carried out to ensure the accuracy of data.

## Data analysis

Data analysis will be performed by professional statisticians using SPSS 22.0. Three data sets will be conducted: intention-to-treat, per-protocol set, and safety data set. The intention-to-treat refers to patients who have received treatment at least once and one follow-up visit; an intentional analysis will be conducted for curative effect. The per-protocol set refers to all cases that do not violate the protocol and complete the programme; per-protocol set analysis will be conducted for curative effect. The safety data set refers to the randomized cases that take a tested drug at least once with safety evaluation data after treatment. We use mean±SD for continuous variables and percentages for categorical variables. In measured indices, the independent t-test will be used for hypothesis testing of the normal variables, while the Wilcoxon rank sum test will be used for hypothesis testing of the skewed variables. The  $\chi^2$  test will be used for hypothesis testing of the counted indices. The statistical analyses will use the two sided hypothesis test.  $P \leq 0.05$  will be set as the significant level.

## Ethics and dissemination

The protocol has been approved by the Ethic Committee of the XiYuan Hospital, China Academy of Chinese Medical Sciences (identifier 2018XLA03I-3); Ethics Committee of the Longhua Hospital Shanghai University of Traditional Chinese Medicine (identifier 2018LCSY034); Ethics Committee of the Guangdong Provincial Hospital of Traditional Chinese Medicine (identifier BF2018-083-01); Ethics Committee of the Hubei Hospital of Traditional Chinese Medicine (identifier SL2018-C19-01); Ethics Committee of the Affiliated hospital of Chengdu University of Traditional Chinese Medicine (identifier 2018KL-053); Ethics Committee of the Yunnan Provincial Hospital of Traditional Chinese Medicine (identifier 2018LLZ-014-NO.01). The protocol has been registered in the Clinical Trials USA registry (registration No. NCT03658291) on 4 September 2018 [see Additional file 3]. The trial will help to demonstrate if Sanjin tablets is effective and safe for patients with acute uncomplicated lower UTI. We will publish the results of this study in peer-reviewed journals to ensure widespread dissemination.

## Discussion

This study was designed to evaluate the efficacy, safety and recurrence rate of SJT for the patients with acute uncomplicated lower UTI and explore the possibility of using Sanjin tablets to reduce or substitute the use of antibiotics. 252 patients were divided into three groups by randomized, double-blind, double-

dummy, parallel control and multicentre clinical trial. To our knowledge, this is the first study protocol to evaluate the recurrence rate and the effects of reducing or substituting antibiotics of SJT for the treatment of acute uncomplicated lower UTI. This trial aims to evaluate whether the SJT can substitute the use of antibiotics for acute uncomplicated lower UTI by the comparison between experimental group (SJT plus LT placebo) and group 1 (LT plus SJT placebo), to evaluate whether SJT can reduce the use of antibiotics by the comparison between the first 5 days (SJT plus LT ) and the last 2 days (SJT plus LT placebo) in group 2. To facilitate high validity and reliability, a strict quality control and high-quality methodology is indispensable. We describe in detail the method of randomization, allocation concealment, blinding, interventions, recruitment, and data collection. The results from this trial may provide evidence on the effectiveness, safety, recurrence rate and reduce or substitute antibiotics of SJT.

## **Strengths and limitations of this study**

- This is a well-designed study to assess the efficacy, safety and recurrence rate of Sanjin tablets for acute uncomplicated lower urinary tract infection in adults.
- The results from this randomized, double-blind, double-dummy, parallel control of positive drug, multicentre clinical trial will provide new evidence of the efficacy and recurrence rate of Sanjin tablets for acute uncomplicated lower urinary tract infection.
- This study will provide evidence of Sanjin tablets for reducing or substituting the use of antibiotics for acute uncomplicated lower urinary tract infection, which can guide rational application of antibiotics..
- This trial is implemented in six hospitals in Chinese subjects; this can strengthen its generalisability.
- One limitation is the results of participant symptoms evaluate scales might have subjective factors.
- Another limitation is the participant symptoms evaluate scales, which might exaggerate the severity of the symptoms of acute uncomplicated lower urinary tract infection.

## **Trial status**

This trial was registered in the Clinical Trials USA registry (registration No. NCT03658291) on 4 September 2018. Recruitment will begin in January 2019 and it is anticipated that completed enrollment in December 2019.

## **Declarations**

## **Acknowledgements**

The authors acknowledge Professor GZ from the Xi Yuan Hospital, China Academy of Chinese Medical Sciences, Professor DYY from the Longhua Hospital Shanghai University of Traditional Chinese Medicine, Professor XST from the Guangdong Provincial Hospital of Traditional Chinese Medicine, Professor GWX from the Hubei Hospital of Traditional Chinese Medicine, Professor ZWT from the Affiliated hospital of Chengdu University of Traditional Chinese Medicine, Professor ZCH from the Yunnan Provincial Hospital of Traditional Chinese Medicine for their generous assistance in the application and preparation of the study. The authors are also grateful to the China International Food and Medicine Exchange Center of NMPA, the Central Public Welfare Research Institutes and the China Academy of Chinese Medical Sciences for funding this study. All authors revised the protocol critically for important intellectual content and approved the final manuscript.

## **Funding**

This study is supported by the China International Food and Medicine Exchange Center of NMPA Commissioned Research Project “International Publicity on the Safety of Traditional Chinese Medicine” (Z0531); Fundamental Research Funds for the Central Public Welfare Research Institutes (Z0546); Scientific Research Innovation Team Project of China Academy of Chinese Medical Sciences (PY1303); Research Project of Postgraduate Education and Teaching Reform of China Academy of Chinese Medical Sciences (JG201703). The funders had no role in the design of the study and collection, analysis, and interpretation of data and in writing the manuscript.

## **Authors' contributions**

LJ is first author who wrote the first draft of the manuscript and contributed to the design of the study. XYM and GZ are the senior authors who refined the protocol and the principal investigators of this study. SJW, DYY, XST, GWX, ZWT, ZCH, WLX contributed to the trial. YDH, WZF are the medical statisticians for the study, contributed to the statistical design, acquisition and analysis of data. All authors revised the protocol critically for important intellectual content and approved the final manuscript.

## **Ethics approval and consent to participate**

The protocol has been approved by the Ethics Committee of the XiYuan Hospital, China Academy of Chinese Medical Sciences (2018XLA03I-3), the Longhua Hospital Shanghai University of Traditional Chinese Medicine (2018LCSY034), the Guangdong Provincial Hospital of Traditional Chinese Medicine (BF2018-083-01), the Hubei Hospital of Traditional Chinese Medicine (SL2018-C19-01), the Affiliated hospital of Chengdu University of Traditional Chinese Medicine (2018KL-053), the Yunnan Provincial Hospital of Traditional Chinese Medicine (2018LLZ-014-NO.01). Based on the Declaration of Helsinki,

written informed consent will be will be obtained from all study participants. Any modifications to the protocol that may impact the conduct of the study, the potential benefits to the patients, or patient safety will require a formal amendment to the protocol, which should be approved by the ethics committee prior to implementation. Protocol modifications will be communicated to all centers involved through regular meetings and telephone conversations. All staff will be notified, trained, and qualified prior to conducting the trial.

All subject-related information including case reports, laboratory specimens, and evaluation forms will be kept strictly confidential. All records will be kept in a secure, locked place and secured with password-protected access systems. To protect confidentiality, identification information will be deleted from all study documents

## Consent for publication

Written informed consent will be taken from all participants prior to their taking part in the study.

## Competing interests

The authors declare that they have no competing interests.
