Abstract

Background

Cough hypersensitivity is a major characteristic feature associated with several types of cough, including chronic cough, but its underlying mechanisms remain to be fully understood. Inflammatory mediators, such as prostaglandin E₂ (PGE₂), have been implicated in peripheral induction/sensitization of the cough reflex. In this study, using a conscious guinea pig model of cough, we investigated whether PGE₂ can sensitize the cough reflex via central actions and, if so, via which mechanisms.

Methods

All drugs were administered by intracerebroventricular (i.c.v.) route and whole-body plethysmograph set-up was used for both induction, using aerosolized citric acid (0.2 M), and recording of cough. Immunohistochemistry was performed to confirm the expression of NaV 1.8 channels in the nucleus tractus solitarius (nTS).

Results

We show that both PGE₂ and the non-selective EP1/EP3 agonist, sulprostone, dose-dependently enhanced the citric acid-induced cough ($P \leq 0.001$, $P \leq 0.01$, respectively). Pretreatment with the EP1 antagonist, ONO-8130, did not affect the sulprostone-induced cough sensitization, whilst the EP3 antagonist, L-798,106, dose-dependently inhibited this effect ($P \leq 0.05$). Furthermore, treatment with either the EP2 agonist, butaprost or the EP4 agonist, L-902,688, had no effect on cough sensitization. Additionally, pretreatment with either the TRPV1 antagonist, JNJ-17203212 or the TRPA1 antagonist, HC-030031, alone or in combination, nor with the NaV 1.1, 1.2, 1.3, 1.4, 1.6 and 1.7 channel blocker, tetrodotoxin, had any effect on the cough. In contrast, pretreatment with the NaV 1.8 antagonist, A-803467, dose-dependently inhibited this effect ($P \leq 0.05$). Furthermore, NaV 1.8 channels were shown to be expressed in the nTS.

Conclusion

Collectively, our findings show that PGE₂ sensitizes the cough reflex centrally via EP3 receptor-dependent activation of NaV 1.8 but independently of TRPV1/TRPA1 and TTX-sensitive sodium channel activation. These results indicate that PGE₂ plays an important role in central sensitization of the cough reflex and suggest that central EP3 receptors and/or Nav 1.8 channels may represent novel antitussive molecular targets.

Impact Statement

Cough is the most common clinical complaint and associated with very high sales of the over the counter (OTC) anti-tussive drugs documented in the industrialized countries. However, the current anti-tussive drugs provide very little therapeutic benefit and also associated with very high side effect profile. Therefore, there is a strong need for better understanding of the mechanisms underlying cough so that more effective therapy can be developed. Neuroinflammation has recently been shown to play an important role in cough. In this study, we show, for the first time, that the ubiquitous proinflammatory mediator PGE₂ sensitizes the cough reflex via a central mechanism of action. We also show that this is specifically mediated via the EP3 receptor-dependent activation of the NaV 1.8 sodium channels that are highly expressed in the nTS.

Background

Cough, particularly that of a chronic nature, continues to be a challenging clinical condition with a high global prevalence leading to a significant economic expenditure and utilization of health care resources (1, 2). The term “Cough Hypersensitivity Syndrome” (CHS) has been recently coined and differentiates the exaggerated cough associated with airway diseases and chronic cough from the normo-protective cough response (3). The lack of effective cough therapy in the market, to date, reflects our incomplete understanding of cough mechanisms and related pathways that underlie CHS.

The role of the brainstem and higher brain regions is particularly poorly understood, compared to that of the airways, possibly due to difficulty of access, complexity of the neuroanatomy and lack of appropriate animal models (4–9). Notwithstanding, progress has been made recently in identifying some of the neuromediators, pathways and neuroplastic changes involved in CHS at both peripheral and central levels (10, 11).

There is a growing body of evidence suggesting that airway and central neuroplastic changes, driven by inflammation, are important drivers of cough. Interestingly, many of the inflammatory mediators involved in hyperalgesia, such as substance P (SP), nerve growth factor (NGF) and bradykinin (BK) also induce and/or sensitize the cough reflex (12–17) partly via activation and/or upregulation of ion channels. In particular, transient resistant potential (TRP) channels such as TRPV1 and TRPA1 have been reported to play key roles in sensitizing the cough reflex both peripherally and centrally (12, 13, 18, 19). More recently, voltage-gated sodium channels (NaVs), mainly NaV 1.7, 1.8 and 1.9, which are expressed in airway sensory neurons, have been reported to be involved in the regulation of peripheral cough (20–22).

Prostaglandin E₂ (PGE₂), a major mediator of pain, has been demonstrated, paradoxically, to have both proinflammatory and protective bronchodilator effects in the respiratory system (23), particularly when given by inhalation (24, 25). Moreover, several preclinical and clinical studies have shown that aerosolization of PGE₂ can both induce and sensitize the cough reflex to citric acid and/or capsaicin (24, 26, 27). Indeed, treatment with NSAIDs can reduce virally-induced cough and cough associated with angiotensin converting enzyme (ACE) inhibitors suggesting an important role for PGE₂ in cough induced via these modalities (28, 29).

The actions of PGE₂ are mediated predominantly through E-prostanoid (EP) receptors, which are classified into four distinct subtypes: EP1, EP2, EP3 and EP4 (30, 31). EP receptors are 7-transmembrane G-protein coupled receptors (GPCR) that differ in their G-protein coupling and signaling cascade. The EP3 receptors exists in multiple splice variants produced by alternative splicing of the C-terminal tail. Whilst all the EP receptors have been reported to have airway effects, good evidence suggests that the EP3 receptor is the main receptor involved in PGE₂-sensitization and induction of cough at the airway level (24). However, whether PGE₂ can sensitize the cough reflex via a central action, and if so, via what mechanisms, has not been previously addressed.

Based on our previous findings with inflammatory mediators and the evidence supporting the role of PGE₂ in peripheral induction and sensitization of the cough reflex, we proposed that PGE₂ also sensitizes the cough reflex centrally. In this study, and using a conscious guinea pig model of cough, we investigated (1) whether PGE₂ administered centrally can sensitize the cough reflex and if so, (2) what are the downstream signaling mechanisms involved.

Materials And Methods

Ethical considerations

All the experimental protocols were approved by the Animal Ethics Committee in the Health Sciences Center at Kuwait University. In addition, all the experiments were conducted in accordance with international and Kuwait University guidelines and complied with the EU Directive 2010/63/EU for animal experiments and the National Institutes of Health Guide for the care and use of laboratory animals (NIH Publications No. 8023, revised 1978).

Animals

Conscious, unrestrained adult Dunkin-Hartley guinea pigs, both males and females, weighing 400-600 g were used for all the experiments in this study. The in- house bred animals were generously supplied by the Animal Resources Center of Faculty of Medicine at Kuwait University and were housed in a fully controlled room in the animal facility maintained at 21-25°C, relative humidity of 50% and 12-h light/dark cycle. Following cannulae implantation, all animals were placed individually in plastic cages on sawdust bedding to avoid removal or damage to the implanted cannula. The animals had unrestricted access to standard diet and tap water supplemented with multivitamins.

Surgical implantation of chronic intracerebroventricular cannula

The surgical implantation procedures were performed as previously described (14). Guinea pigs were first anesthetized with ketamine hydrochloride 80 mg/kg (Laboratories Sterop, Brussels, Belgium) and xylazine hydrochloride 6 mg/kg (Sigma-Aldrich, St Louis, MO, USA) administered intramuscularly (i.m.). Fifteen minutes thereafter, each animal was injected with the antibiotic enrofloxacin 0.25 mg/kg (s.c.) (Bayer AG, Berlin, Germany) and the pain control medication, tramadol hydrochloride 1 mg/kg (i.m.) (Sigma-Aldrich, St Louis, MO, USA). The fur over the guinea pig head was shaved off and the animal was then placed in a stereotaxic apparatus (David Kopf Instruments, Tujunga, CA, USA). The head was cleaned with betadine, a midline incision in the skin above the skull (2 cm) was made with a sharp surgical blade No. 20 (Feather Safety Razor, Osaka, Japan), and the skull was cleaned with 3% hydrogen peroxide (Sigma-Aldrich, St Louis, MO, USA) to ensure that all connective tissues were removed from the surface of the skull. A 20-gauge stainless steel guide cannula and its dummy cannula, HTX-20T and HTX-25R (Plastic one, Roanoke, VA, USA) were placed in the lowering arm of the stereotaxic apparatus. The cannula was moved in the following three dimensions relative to the bregma and corresponded to the left lateral ventricle: 2.0 mm anteroposterior (AP), 1.8 mm mediolateral (ML) and 4.8 mm dorsoventral (DV), which is based on previously published reports (14, 32, 33). A small hole was then drilled in the skull, based on the determined coordinates. Two additional holes were drilled for two anchor screws (Stoelting, IL, USA). Dental cement (Stoelting, IL, USA) was used to fix the cannula in the predetermined coordinates. The animals were also treated with intramuscular tramadol hydrochloride (1 mg/kg) and subcutaneous enrofloxacin (0.25 mg/kg) for two consecutive days to relieve pain and prevent post-operative infections.

Preparation of drugs and buffers

PGE₂ (Cayman Chemical Company) was initially prepared by dissolving the drug in absolute ethanol and dilutions were made in artificial cerebrospinal fluid (ACSF) to yield the desired final concentrations. Sulprostone, butaprost, L-902,688, ONO-8130, L-798,106, A-803467 (Cayman Chemical Company), JNJ-17203212 (Tocris Bioscience) and HC-030031 (Sigma Aldrich) were initially dissolved in DMSO and subsequent dilutions were made in ACSF to yield the desired final concentrations as shown in table1. Tetrodotoxin (Tocris Bioscience) was initially dissolved in ACSF to make 1 mM solution and subsequent dilutions were made in ACSF to yield the desired final concentration. Citric acid (Sigma Aldrich) was dissolved in phosphate buffer saline (PBS) (Sigma Aldrich) to make 0.2 M solution. All drugs were freshly prepared for each experiment.

Intracerebroventricular drug administration

The drugs were administered to conscious and unrestrained guinea pigs on day 8 after cannula implantation as previously described (14, 32, 33). Briefly, prior to each cough assessment experiment, the dummy cannula was removed from the guide cannula. The infusion cannula was then connected to the guide cannula and a vehicle/drug filled syringe fixed to a Harvard 33 Twin Syringe Pump (Harvard Apparatus, USA) via a polyethylene tubing (PE-20) (Small parts, INC, USA). Drugs were infused at a rate of

30 µl/h, with a maximum volume of 15 µl administered over a period of 30 minutes followed by a 15-minute absorption period to prevent the backflow of the drug and allow the drug to equilibrate. In the experiments involving agonists and antagonists treatments, the agonist drug was administered 45 minutes after the antagonist pretreatment (30-minute antagonist infusion followed by 15-minute absorption phase). The accuracy of the cannula implantation was checked via the infusion of methylene blue at the end of some of the experiments and an 80% accurate implantation was noted.

Citric acid challenge and measurement of cough

The citric acid challenge and the assessment of cough were conducted using the Buxco whole body plethysmography (WBP) system (Buxco, Troy, NY, USA) as previously described (14, 34). Fifteen minutes following the infusion of the drug, conscious and unrestrained guinea pigs were placed individually in the transparent plethysmography chambers. The animals were then exposed to an aerosolized 0.2 M aqueous citric acid (Sigma-Aldrich, St Louis, MO, USA), which is generated by the aerogen nebulizer. The bias flow generator, which is connected to the plethysmography chamber, was set to supply air at a rate of 3 L/min and withdraw air at a rate of 4 L/min. The number of coughs were recorded over a 20-min period, which was divided into 10-min of citric acid challenge followed by 10-min post-nebulization recording period, using the Buxco cough analyzer. The Buxco cough analyzer differentiates coughs from sneezes and has been reported to demonstrate > 99% correlation with manual cough counting (34). The criteria and number of coughs were also confirmed by observing the characteristic opening of the mouth, forward movement coupled to the high sound produced by the guinea pigs as well as a defined pattern in the sound signal. The overall timeline of the experimental protocols used to investigate PGE₂-induced sensitization of the cough reflex is shown in Figure-1.

Animal perfusion and qualitative immunohistochemistry (IHC) study for the expression of NaV 1.8 channels in the brainstem nucleus, nTS.

Due to the scarcity of data for central expression of NaV 1.8 channels, a qualitative IHC studies were conducted to detect the expression of NaV 1.8 channels in the brainstem nucleus, nTS, in few guinea pigs. The Guinea pigs were anesthetized with ketamine hydrochloride 80 mg/kg (Laboratoires Sterop, Brussels, Belgium) and xylazine hydrochloride 6 mg/kg (Sigma-Aldrich, St Louis, MO, USA) administered intramuscularly (i.m.) and perfused transcardially with freshly prepared 4% paraformaldehyde. Briefly, the heart was exposed and perfused with 150 mL of heparinized saline followed by 800 mL of 4% paraformaldehyde (in 0.1M Phosphate buffer, pH 7.4). The brain was dissected out and post fixed for 48 h in the same fixative. Five mm length of medulla oblongata tissue starting from obex towards the spinal cord was processed for paraffin section cutting. Five-micron thick serial sections were cut and mounted on Poly-L-lysine coated glass slides. Serial brain sections were stained for cresyl violet staining and double immunofluorescence staining for NaV1.8 and NeuN (marker for Neuron). Selected sections were incubated in a cocktail of polyclonal rabbit anti-Nav1.8 (1:250, NBP2-75584, Novus Biologicals) and monoclonal mouse anti-NeuN-1 (1:500, ab104224, Abcam) antibodies overnight. The sections were then

washed in PBS and treated with a cocktail of goat anti-rabbit DyLight-594 and horse anti-mouse DyLight 488 secondary antibodies (1:200, DI-2488-1.5, Vector Laboratories). Sections were washed and mounted with vectashield mounting media. Sections were observed and photographed in the confocal microscope.

Animal euthanization

At the end of each experiment, animals were sacrificed by carbon dioxide (CO₂) inhalation. The CO₂ gas was delivered using a compressed gas cylinder, pressure regulator and flowmeter. The flow rate of CO₂ was adjusted to 5 L/min and maintained until breathing, all muscle activity and signs of life are completely absent. This was followed by cervical dislocation to ensure death.

Experimental protocols

The present study consisted of several experiments summarized in table 1. In all experiments, animals were arbitrarily divided into control group and two or three treatment groups. Control groups were treated with 15 ml of different vehicles that were used to dissolve the agonists or antagonists. Animals in the treatment groups were treated with 15 ml of different concentrations of agonists and/or antagonists.

Statistical analysis

Statistical evaluation analysis was carried out with Microsoft Excel for Mac (Microsoft Software V 15.31, USA) and GraphPad Prism (GraphPad Software, San Diego, CA). The data were analyzed blindly and expressed as mean cough $\pm$ standard error of the mean (SEM) and represent the number of coughs during the 20-minute period of assessment. All treatment groups were initially tested for normality using Shapiro-Wilk test of normality. Normally distributed data were analyzed by parametric one-way analysis of variance (ANOVA), followed by Dunnett's multiple comparisons test. Nonparametric data were analyzed using nonparametric Kruskal-Wallis ANOVA followed by Dunn's multiple comparison. At $P \leq 0.05$, differences were considered statistically significant. All the groups in each experiment were time-matched to ensure all treatment groups were exposed to the same experimental conditions.

Results

Effect of treatment with PGE₂ on citric acid-induced cough

Treatment of guinea pigs with PGE₂; i.c.v. (0.3 mg/ml; n = 8, 0.6 mg/ml; n = 12 and 1 mg/ml; n = 13) resulted in a dose-dependent increase in citric acid-induced cough response compared to vehicle treated guinea pigs (n = 12). The mean cough $\pm$ SEM were the following: 5.25 $\pm$ 1.53 (0.3 mg/ml PGE₂), 7.58 $\pm$ 1.28 (0.6 mg/ml PGE₂), 16.31 $\pm$ 3.16 (1 mg/ml PGE₂) and 2.75 $\pm$ 0.94 (vehicle). Both 0.6 mg/ml and 1

mg/ml resulted in a significant increase in citric acid-induced cough ($> 175\%$, $P = 0.035$; $> 490\%$, $P = 0.0001$, respectively). The data are presented in figures (2A) and (2B). Since PGE₂ at concentration of 1 mg/ml resulted in the highest enhancement of the citric acid-induced cough without any overt unwanted effects, this dose was used in the subsequent experiments in this study involving the use of PGE₂.

Effect of treatment with the non-selective EP1/EP3 agonist, sulprostone, on citric acid-induced cough

Treatment of guinea pigs with the non-selective EP1/EP3 agonist, sulprostone; i.c.v. (0.1 mg/ml; $n = 8$, 0.3 mg/ml; $n = 7$ and 1 mg/ml; $n = 9$) resulted in a dose-dependent increase in citric acid-induced cough response compared to vehicle treated guinea pigs ($n = 9$). The mean cough $\pm$ SEM were the following: 6 ± 2.2 (0.1 mg/ml sulprostone), 8.29 ± 1.9 (0.3 mg/ml sulprostone), 10.33 ± 1.33 (1 mg/ml sulprostone) and 3.44 ± 1.3 (vehicle). Sulprostone at 1 mg/ml caused a significant increase in citric acid-induced cough ($> 200\%$, $P = 0.007$). The data are presented in figures (3A) and (3B). Since sulprostone at concentration of 1 mg/ml resulted in significant enhancement of the citric acid-induced cough, this dose was used in the subsequent experiments involving the use of sulprostone.

Effect of pretreatment with the EP1 receptor antagonist, ONO-8130, on sulprostone-enhanced citric acid-induced cough

Pretreatment of guinea pigs with the EP1 antagonist, ONO-8130; i.c.v. (1 mg/ml; $n = 7$ and 5 mg/ml; $n = 6$) did not affect the sulprostone-enhancement of citric acid-induced cough response compared to vehicle pretreated guinea pigs ($n = 10$). The mean cough $\pm$ SEM were the following: 15.71 ± 2.92 (1 mg/ml ONO-8130), 16.83 ± 4.45 (5 mg/ml ONO-8130) and 15.80 ± 5.67 (vehicle). The data are presented in figures (4A) and (4B).

Effect of pretreatment with the EP3 receptor antagonist, L-798,106, on sulprostone-enhanced citric acid-induced cough

Pretreatment of guinea pigs with the EP3 antagonist, L-798,106; i.c.v. (2.5 mg/ml; $n = 7$, 5 mg/ml; $n = 10$) resulted in a dose-dependent inhibition of the sulprostone-enhancement of citric acid-induced cough response compared to vehicle pretreated guinea pigs ($n = 10$). The mean cough $\pm$ SEM were the following: 8.29 ± 1.69 (2.5 mg/ml L-798,106), 6.20 ± 1.88 (5 mg/ml L-798,106) and 16.30 ± 3.49 (vehicle). L-798,106 at 5 mg/ml but not 2.5 mg/ml significantly reduced the sulprostone-enhancement of citric acid-induced cough response by 62 % ($P = 0.022$). The data are presented in figures (5A) and (5B).

Effect of treatment with the EP2 agonist, butaprost, on citric acid-induced cough

Treatment of guinea pigs with the selective EP2 agonist, butaprost; i.c.v. (0.3 mg/ml; $n = 8$ and 1 mg/ml; $n = 10$) did not affect the citric acid-induced cough response compared to vehicle treated guinea pigs ($n = 11$). The mean cough $\pm$ SEM were the following: 2.50 ± 1.56 (0.3 mg/ml butaprost), 2.60 ± 1.10 (1 mg/ml butaprost) and 2.27 ± 0.93 (vehicle). The data are presented in figures (6.A) and (6.B).

Effect of treatment with the EP4 agonist, L-902,688, on citric acid-induced cough

Treatment of guinea pigs with the selective EP4 agonist, L-902,688; i.c.v. (0.3 mg/ml; n = 9 and 1 mg/ml; n = 8) did not affect the citric acid-induced cough response compared to vehicle treated guinea pigs (n = 7). The mean cough $\pm$ SEM were the following: 2.33 ± 1.29 (0.3 mg/ml L-902,688), 2.38 ± 0.92 (1 mg/ml L-902,688) and 2.29 ± 1.25 (vehicle). The data are presented in figures (7A) and (7B).

Effect of pretreatment with the TRPV1 antagonist, JNJ-17203212, on PGE₂-enhanced citric acid-induced cough

Pretreatment of guinea pigs with the TRPV1 channel antagonist, JNJ-17203212; i.c.v. (0.4 mg/ml; n = 10, 1.3 mg/ml; n = 9) did not affect the PGE₂-enhancement of citric acid-induced cough response compared to vehicle pretreated guinea pigs (n = 10). The mean cough $\pm$ SEM were the following: 11.00 ± 4.55 (0.4 mg/ml JNJ-17203212), 10.67 ± 2.62 (1.3 mg/ml JNJ-17203212) and 12.10 ± 1.92 (vehicle). The data are presented in figures (8A) and (8B).

Effect of pretreatment with the TRPA1 antagonist, HC-030031, on PGE₂-enhanced citric acid-induced cough

Pretreatment of guinea pigs with the TRPA1 channel antagonist, HC-030031; i.c.v. (0.02 mg/ml; n = 7, 0.05 mg/ml; n = 6) did not affect the PGE₂-enhancement of citric acid-induced cough response compared to vehicle pretreated guinea pigs (n = 8). The mean cough $\pm$ SEM were the following: 11.57 ± 3.60 (0.02 mg/ml HC-030031), 13.00 ± 3.48 (0.05 mg/ml HC-030031) and 14.25 ± 2.29 (vehicle). The data are presented in figures (9A) and (9B).

Effect of pretreatment with combined doses of JNJ-17203212 and HC-030031 on PGE₂-enhanced citric acid-induced cough

Pretreatment of guinea pigs with combined doses of JNJ-17203212 and HC-030031, i.c.v., at either low (0.4 mg/ml and 0.02 mg/ml; n = 5) or high doses (1.3 and 0.05 mg/ml; n = 6) did not affect the PGE₂-enhancement of citric acid-induced cough response compared to vehicle pretreated guinea pigs (n = 7). The mean cough $\pm$ SEM were the following: 11.40 ± 2.50 (low-dose combination), 10.17 ± 2.66 (high-dose combination) and 10.71 ± 1.95 (vehicle). The data are presented in figures (10.A) and (10.B).

Effect of pretreatment with the tetrodotoxin, TTX, on PGE₂-enhanced citric acid-induced cough

Pretreatment of guinea pigs with the tetrodotoxin, TTX; i.c.v. (0.015 mg/ml; n = 7, 0.1 mg/ml; n = 5) did not affect the PGE₂-enhancement of citric acid-induced cough response compared to vehicle pretreated guinea pigs (n = 7). The mean cough $\pm$ SEM were the following: 15.29 ± 4.98 (0.015 mg/ml TTX), 16.60 ± 3.61 (0.1 mg/ml TTX) and 18.14 ± 4.75 (vehicle). The data are presented in figures (11A) and (11B).

Effect of pretreatment with the NaV 1.8 antagonist, A-803467, on PGE₂-enhanced citric acid-induced cough

Pretreatment of guinea pigs with the Nav1.8 channel antagonist, A-803467; i.c.v. (5 mg/ml; n = 5, 10 mg/ml; n = 5) resulted in a dose-dependent inhibition of the PGE₂-enhancement of citric acid-induced cough response compared to vehicle pretreated guinea pigs (n = 6). The mean cough $\pm$ SEM were the following: 8.80 ± 1.79 (5 mg/ml A-803467), 4.40 ± 1.97 (10 mg/ml A-803467) and 19.33 ± 5.00 (vehicle). A-803467 at 10 mg/ml significantly reduced the PGE₂-enhancement of citric acid-induced cough response by 77 % (P = 0.018). The data are presented in figures (12A) and (12B).

The expression of NaV 1.8 channels on the brainstem nucleus, nTS of guinea pigs

Immunohistochemistry using a polyclonal NaV 1.8 antibody confirmed the expression of NaV 1.8 channels in the nTS. NaV 1.8 channels were clearly expressed within all the neurons of the brainstem nucleus, nTS, of guinea pigs. The data are presented in figure (13). The nTS was identified with reference to the stereotaxic atlas of the guinea pig brainstem.

Discussion

In this study we show, using a conscious guinea pig model of cough, that acute exposure to PGE₂, via the central route, results in central sensitization of the cough reflex which is mediated via EP3 receptor-dependent activation of NaV 1.8 channels but independent of TRPV1, TRPA1 or TTX-sensitive channels activation.

Inflammatory mediators have been reported to play a role in the sensitization of cough at both peripheral and central levels. Elucidating the mechanism by which this is achieved will not only result in better understanding of the cough mechanisms but will also result in identification of novel targets for cough therapy.

Our data show that acute exposure to PGE₂, via the i.c.v route, resulted in a dose-dependent enhancement of the citric acid-induced cough. The enhancement effect of PGE₂ was observed shortly after its administration and occurs over the same time frame seen with other inflammatory mediators such as NGF and BK (12, 14). These findings show that PGE₂ plays a role in the central sensitization of the cough reflex, in agreement with both clinical and preclinical studies, both *in vitro* and *in vivo*, which show that PGE₂ can sensitize the cough reflex/airway vagal nerves (26, 27, 35, 36). Our findings are also in line with studies in the pain field where PGE₂ is reported to be involved in the central mechanisms that underlie the sensitization of pain pathways leading to hyperalgesia. For example, both intrathecal (i.t.) and i.c.v. administration of PGE₂ result in a dose-dependent enhancement of sensitivity to pain in mice and rats (37–40).

The specific site in the brainstem where PGE₂ acts to enhance the cough reflex has not been determined in this study. However, several studies have previously identified the nucleus tractus solitarius (nTS) as a likely site. For example, the enhanced release of several excitatory mediators of the synaptic transmission in the nTS such as glutamate and SP is proposed to result in synaptic plasticity and central sensitization

of the cough reflex (14, 41–44). Conversely, the injection of neurokinin1 (NK1) or glutamate receptor antagonists, AP-5 and CNQX, into this brain region has been reported to inhibit cough (45, 46). Nuclei such as paratrigeminal nucleus (Pa5) may also be involved, not only as a relay point for the airway nerves, but also as a site for sensitization of the airway input signal.

All four EP receptors are reportedly expressed in the brainstem/nTS and have a high affinity for PGE₂ (47–49) and could all potentially be involved in mediating the central tussive actions of PGE₂. A pharmacological approach using selective agonists and antagonists, when the selectivity of an agonist to a specific sub-type was not high, were used to rule in or out the involvement of a particular EP receptor sub-type (50).

Sulprostone, a non-selective agent with high affinity for both EP1 and EP3 receptors, was used to explore whether EP1 and/or EP3 receptors mediate the central PGE₂ enhancement of the cough response to citric acid (47, 51). Our data show that treatment with sulprostone, via the i.c.v. route, enhanced cough in a dose-dependent manner. Furthermore, the sulprostone enhanced cough response showed an efficacy and a time course of sensitization similar to that induced by PGE₂, over the same dose range, suggesting that the sensitizing effects of PGE₂ and sulprostone on cough were likely to be mediated via the same receptor subtype/s, namely EP1/EP3. These data are in line with that showing that both sulprostone and PGE₂ induced depolarizations in the isolated guinea-pig vagus nerves, indicating that the activation of sensory nerves was also dependent on EP1/EP3 receptor subtype activation (24). Furthermore, a role for EP1/EP3 in central sensitization is also supported by *in vivo* findings showing that i.t. administration of sulprostone induced hyperalgesia and allodynia, in mice and rats, with similar time course to that induced by PGE₂ (38, 52, 53). Altogether, these findings would suggest that PGE₂/sulprostone contribute to the enhanced citric acid-induced cough centrally via activation of EP1 and/or EP3 receptors.

Therefore, to identify which one of the two receptors, or if indeed both, are involved in the sulprostone-enhanced cough, we used selective antagonists for EP1 and EP3 receptors. Our data show that pretreatment with the highly selective EP1 antagonist, ONO-8130, did not inhibit the sulprostone-enhanced citric acid-induced cough indicating that EP1 receptors were not involved in the central sensitization of the cough reflex. Higher doses of ONO-8130 could not be tried because of solubility limitations. In contrast, our data show that pretreatment with the highly selective EP3 antagonist, L-798,106 dose-dependently decreased the sulprostone-enhanced citric acid-induced cough. These findings clearly show that the effect of PGE₂ in central sensitization of the cough reflex is mediated, at least in part, via activation of EP3 receptors. This observation is in line with findings from a recent study, using both *in vitro* and *in vivo* approaches, that identified EP3 as the key receptor in mediating PGE₂-induced sensory nerve activation as well as cough induction, when administered peripherally (24). Our results are also in line with data from pain studies which report that EP3 receptors mediate the PGE₂-induced central sensitization of pain. For example, activation of spinal, or supra-spinal EP3 receptors had been reported to play an important role in the development of hyperalgesia and allodynia in mice and rats (38, 40, 52–54). However, some studies have not been able to report a role for EP3 receptors in PGE₂-induced central

sensitization of pain (55). These differences in findings may be due to the fact that unlike other EP receptors, EP3 receptors exist in multiple splice variants isoforms (30, 56) and although these isoforms show similar ligand binding affinities, they differ in their expression between species, G-protein coupling, signal transduction properties, expression pattern and density in various tissues both in normal and disease conditions (57–59).

The highly selective EP2 agonist, butaprost (free acid, FA) and EP4 agonist, L-902,688 were used to explore whether EP2 receptors and EP4 receptors, respectively, mediate the PGE₂ enhancement of cough response to citric acid centrally. Our data show that acute exposure to either butaprost (FA) or L-902,688, via the i.c.v route, did not affect the cough response suggesting that neither EP2 receptors nor EP4 receptors have contributed to the PGE₂-enhanced cough centrally. These findings are in line with the results of an *in vitro* study which reported that neither EP2 receptors nor EP4 receptors were involved in the PGE₂-induced depolarization of vagal sensory nerves isolated from guinea pigs and mice (24). Our results are also in agreement with findings from several pain studies which have reported that central EP2 and EP4 receptors were not involved in central sensitization of pain. Of particular interest, are the findings of a study showing that the i.c.v administration of butaprost in rats had no effect on the nociceptive processing following mechanical and thermal stimulation (40). Moreover, it has been shown that the spinal application of an EP4 agonist did not alter the responses of dorsal horn neurons to mechanical stimulation of the inflamed knee (59). Some studies have nonetheless provided evidence for a role for EP2 and EP4 receptors in central sensitization of pain pathways (53, 59, 60).

We also investigated whether TRP channels, specifically TRPV1 and TRPA1, are the downstream effectors of EP3 receptor activation and central sensitization of the cough reflex. These channels have been reported to be involved in cough induced/enhanced by other inflammatory mediators as well as in EP3 receptor- mediated sensory nerve activation and peripheral cough (12, 61, 62). Our data show that pretreatment with neither the selective and potent TRPV1 antagonist, JNJ-17203212, nor TRPA1 antagonist, HC-030031 inhibited the PGE₂-enhanced citric acid-induced cough. These data indicate that these channels are not involved in PGE₂-induced central sensitization of the cough reflex. However, based on the small reduction that was noted with the individual drugs, as well as good evidence of positive interaction between TRPV1 and TRPA1 channels, we postulated that perhaps both channels may need to be blocked in order to see any significant degree of inhibition. Our data show that pretreatment with combined doses of JNJ-17203212 and HC-030031 (low and high doses) did not affect the PGE₂-enhancement of citric acid-induced cough response thus confirming that neither TRPV1 nor TRPA1 channels are involved in PGE₂- induced central sensitization of the cough reflex.

Given that many studies have reported a critical role for TRP channels in cough, both at peripheral and central level, this was a surprising finding (63–65). A possible explanation is that because EP3 receptors exist in multiple isoforms coupled to different G proteins (30, 56) and have different expression patterns between peripheral and central levels in guinea pigs (66), EP3 receptors may utilize different signaling mechanisms, centrally, that do not involve activation of TRP channels. Furthermore, recent findings from

clinical studies have shown that the use of different TRPV1 antagonists failed to improve cough in patients with chronic refractory cough (12, 13, 65–67), further questioning the role of TRPV1 in cough.

Finally we investigated whether voltage gated sodium channels, tetrodotoxin (TTX)-sensitive (NaV1.1, 1.2, 1.3, 1.4, 1.6 and 1.7) and the TTX-resistant channel, specifically NaV 1.8, are coupled to EP3 receptor activation and involved in the central sensitization of the cough reflex. The link between PGE₂ and NaVs has been investigated because PGE₂ was shown to potentiate both TTX-sensitive and TTX-resistant currents in different neuronal cells (67–70). In addition, these channels, particularly NaV 1.7, 1.8 and 1.9, have been recently reported to be expressed in sensory neurons and involved in the regulation of peripheral cough (20, 22, 71, 72). Furthermore, a large body of evidence has shown that these channels are upregulated in inflammatory conditions and in response to specific inflammatory mediators including PGE₂ (73–77).

Our data show that pretreatment with the potent neurotoxin, TTX, via the i.c.v. route, failed to inhibit the PGE₂-enhanced citric acid-induced cough suggesting that TTX-sensitive channels are not involved in PGE₂-induced central sensitization of the cough reflex. This lack of effect was not dose related as TTX was shown to have clear pharmacological effects with comparable doses used in previous studies (78, 79). Moreover, higher doses of TTX (above 0.1 µg/ml) couldn't be tested since they induced vasomotor and respiratory side effects. In contrast to our data, peripheral cough studies have shown that pretreatment of mice with TTX significantly reduced the cough response to 0.25 M citric acid which would imply that these channels are more important peripherally (80). Some, but not all, preclinical pain studies also support the involvement of TTX-sensitive channels in models of hyperalgesia (79). Therefore, the precise role for TTX-sensitive channels in pain remains unclear.

A-803467 is a potent and highly selective NaV 1.8 antagonist which has been widely used to investigate the role of these channels in pain and cough studies. Our data show that pretreatment with A-803467, via the i.c.v. route, dose-dependently decreased the PGE₂-enhanced citric acid-induced cough. This suggests that NaV 1.8 channels, (TTX-resistant sodium channels), mediate the PGE₂-induced central sensitization of the cough reflex. Our results are in agreement with a recent study reporting that both local and systemic administration of A-803467 reduced the number of coughs induced by capsaicin challenge suggesting a role of NaV 1.8 channels in peripheral cough (81). Furthermore, findings from several *in vitro* and *in vivo* pain studies have demonstrated a critical role for NaV 1.8 channels in blocking the excitability of sensory neurons and hyperalgesia (82–84). Interestingly, our results are also consistent with findings from pain studies suggesting a central role for NaV 1.8 channels in the sensitization of pain pathways. For example, the i.t. administration of A-803467 produced a significant effect on diabetes and cancer-induced pain in mice and rats, respectively (85, 86). Furthermore, our immunohistochemistry data also clearly show that NaV 1.8 channels are expressed in the brainstem, specifically in the nTS, and thus lends further support to our pharmacological data. This restricted pattern of expression of NaV 1.8 channels in the nTs makes them an attractive novel molecular target for the treatment of CHS.

Conclusion

In summary, our data show that PGE₂, centrally, enhances citric acid-induced cough via EP3 receptors-dependent activation of NaV 1.8 channels but independently of TRPV1, TRPA1 and TTX-sensitive channels activation. Altogether, our findings support an important role of inflammatory mediators, specifically PGE₂, in driving cough hypersensitivity and identify central EP3 receptors and NaV 1.8 channels as part of an important signaling pathway in enhanced cough. Therefore, targeting central EP3 receptors and/or NaV 1.8 channels may represent a novel approach for the treatment of cough hypersensitivity syndrome.

Declarations

Ethics approval and consent to participate

All the experimental protocols were approved by the Animal Ethics Committee in the Health Sciences Center at Kuwait University. In addition, all the experiments were conducted in accordance with international and Kuwait University guidelines and complied with the EU Directive 2010/63/EU for animal experiments and the National Institutes of Health Guide for the care and use of laboratory animals (NIH Publications No. 8023, revised 1978).

Consent for publication

Not applicable.

Availability of data and materials

The datasets generated during and/or analysed during the current study are available from the corresponding author on reasonable request.

Competing interests

The authors declare that they have no competing interests.

Funding

This study was funded by the College of Graduate studies, Kuwait University and by Kuwait University Research Sector grant number [YP02/18].

Authors' Contributions

AE and AA participated in the design, interpretation of the studies, discussion and interpretation of the data and analysis, and writing and reviewing the manuscript. AA conducted the experiments and the statistical analyses. MR contributed for immunohistochemistry and reviewing the manuscript. All authors read and approved the final manuscript.

Acknowledgements

We are grateful to Ms. Seena Mathews for providing technical assistance throughout this project. We acknowledge the great support of Ms. Ola Zahran from the Animal Resources Center of the Health Sciences Center, Kuwait University.

Figures

Figure 1

A schematic diagram for the overall timeline for the experimental protocol used to investigate PGE₂-induced sensitization of the cough reflex. Intracerebroventricular (i.c.v.) cannulae were implanted and guinea pigs were then injected with tramadol (i.m.) and enrofloxacin (s.c.) for three consecutive days. After a one-week recovery period, drugs were infused through i.c.v. route for 30 minutes followed by a 15-minute absorption phase. In case of two drug treatments, the antagonist was infused first for 30 minutes followed by a 15-minute absorption phase, the agonist was infused for 30 minutes followed by a 15-minute absorption phase. Animals were then challenged with 0.2 M citric acid for 10 minutes followed by a 10-minute post-nebulization recording period. Cough number was assessed over the entire 20-minute nebulization/recording period.

Figure 2

Effect of treatment with PGE₂ on citric acid-induced cough. Treatment of guinea pigs with 15 μ l of PGE₂ (0.3 mg/ml; n=8, 0.6 mg/ml; n=12 and 1 mg/ml; n=13, i.c.v.) resulted in a dose-dependent increase in citric acid-induced cough response compared to vehicle (n=12). Data are plotted as a scatter graph (A) and a bar chart (B), showing mean cough $\pm$ SEM. * and *** represent a statistically significant difference at $P \leq 0.05$ and $P \leq 0.001$, respectively, when compared to vehicle treated animals. Effect of treatment with the non-selective EP1/EP3 agonist, sulprostone, on citric acid-induced cough

Figure 3

Effect of treatment with the non-selective EP1/EP3 agonist, sulprostone, on citric acid-induced cough. Treatment of guinea pigs with 15 μ l of sulprostone (0.1 mg/ml; n=8, 0.3 mg/ml; n=7 and 1 mg/ml; n=9, i.c.v.) resulted in a dose-dependent increase in citric acid-induced cough response compared to vehicle (n=9). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough $\pm$ SEM. ** represents a statistically significant difference at $P \leq 0.01$ when compared to vehicle treated animals.

Figure 4

Effect of pretreatment with the EP1 antagonist, ONO-8130, on sulprostone-enhanced citric acid-induced cough. Pretreatment of guinea pigs with 15 μ l of ONO-8130 (1 mg/ml; n=7 and 5 mg/ml; n=6, i.c.v.) did not affect the sulprostone-enhanced citric acid-induced cough response compared to vehicle (n=10). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough $\pm$ SEM.

Figure 5

Effect of pretreatment with the EP3 antagonist, L-798,106, on sulprostone-enhanced citric acid-induced cough. Pretreatment of guinea pigs with 15 μ l of L-798,106 (2.5 mg/ml; n=7 and 5 mg/ml; n=10, i.c.v.) resulted in a dose-dependent inhibition of the sulprostone-enhanced citric acid-induced cough response compared to vehicle (n=10). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough $\pm$ SEM. * represent a statistically significant difference at $P \leq 0.05$ when compared to vehicle pretreated animals.

Figure 6

Effect of treatment with the EP2 agonist, butaprost, on citric acid-induced cough. Treatment of guinea pigs with 15 μ l of butaprost (0.3 mg/ml; n=8 and 1 mg/ml; n=10, i.c.v.) did not affect the citric acid-induced cough response compared to vehicle (n=11). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough $\pm$ SEM.

Figure 7

Effect of treatment with the EP4 agonist, L-902,688, on citric acid-induced cough. Treatment of guinea pigs with 15 μ l of L-902,688 (0.3 mg/ml; n=9 and 1 mg/ml; n=8, i.c.v.) did not affect the citric acid-induced cough response compared to vehicle (n=7). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough $\pm$ SEM.

Figure 8

Effect of pretreatment with the TRPV1 antagonist, JNJ-17203212, on PGE₂-enhanced citric acid-induced cough. Pretreatment of guinea pigs with 15 μ l of JNJ-17203212 (0.4 mg/ml; n=10 and 1.3 mg/ml; n=9, i.c.v.) did not affect the PGE₂-enhanced citric acid-induced cough response compared to vehicle (n=10). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough $\pm$ SEM.

Figure 9

Effect of pretreatment with the TRPA1 antagonist, HC-030031, on PGE₂-enhanced citric acid-induced cough. Pretreatment of guinea pigs with 15 μ l of TRPA1 antagonist, HC-030031 (0.02 mg/ml; n=7 and 0.05 mg/ml; n=6, i.c.v.) did not affect the PGE₂-enhanced citric acid-induced cough response compared to vehicle (n=8). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough $\pm$ SEM.

Figure 10

Effect of pretreatment with a combination of JNJ-17203212 and HC-030031 on PGE₂-enhanced citric acid-induced cough. Pretreatment of guinea pigs with a 15 µl of combination of TRPV1 antagonist JNJ-17203212 and TRPA1 antagonist, HC-030031 (Comb-L: 0.4 mg/ml and 0.02 mg/ml; n= 5 and Comb-H: 1.3 mg/ml and 0.05 mg/ml; n=6, i.c.v.) did not affect the PGE₂-enhanced citric acid-induced cough response compared to vehicle (n=7). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough ± SEM.

Figure 11

Effect of pretreatment with the TTX-sensitive channel blocker, TTX, on PGE₂-enhanced citric acid-induced cough. Pretreatment of guinea pigs with 15 µl of TTX (0.015 µg/ml; n=7 and 0.1 µg/ml; n=5, i.c.v.) did not affect the PGE₂-enhanced citric acid-induced cough response compared to vehicle (n=7). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough ± SEM.

Figure 12

Effect of pretreatment with the NaV 1.8 antagonist, A-803467, on PGE₂-enhanced citric acid-induced cough. Pretreatment of guinea pigs with 15 μ l of A-803467 (5 mg/ml; n=5 and 10 mg/ml; n=5, i.c.v.) resulted in a dose-dependent inhibition of the PGE₂-enhanced citric acid-induced cough response compared to vehicle (n=6). Data are plotted as a scatter graph (A) and a bar chart (B) showing mean cough $\pm$ SEM. * represent a statistically significant difference at $P \leq 0.05$ when compared to vehicle pretreated animals.

Figure 13

The expression of NaV 1.8 channels on the brainstem nuclei, nTS of guinea pigs A photomicrograph of cross section of the medulla oblongata through the nucleus tractus solitarius, nTS (blue dotted line circle). A higher magnification view of the nTS is shown in the lower panel. Note all neurons of the nTS are positive for NaV 1.8. CC-Central canal. Scale bar= 15 μ m in the upper panel and 30 μ m in the lower panel. Blue dotted line indicates the midline.
