Abstract

Background: In their behavior, Africans generally pour dirty water around their homes. This dirty water becomes stagnant at a given moment, which hence constitutes aquatic habitats (AH). These AH are sought after by mosquitoes for egg-laying and larval development. Recent studies have shown the effectiveness of destroying AH around host habitats (humans and animals) in reducing the incidence of malaria. In this paper, an agent-based model (ABM) is proposed for controlling the incidence of malaria through population sensitizing campaigns on the harmful effects of aquatic habitats around houses.

Methods: The environment is constituted of houses, AH, mosquitoes, humans, and a hospital that will allow humans to heal themselves when they have malaria. The dynamics of malaria's spread is linked to the dynamics of individuals (humans and mosquitoes) populations. The dynamic of the mosquito is represented by two phases: egg-laying and a phase of seeking blood. The dynamic of human is animated by the presence in the health center and houses. Their dynamic also results in hitting the mosquito when a human is bitten by it. Initially, the same number of houses and AH have been considered. Thereafter, houses are fixed and the AH are destroyed each time by 10% of the number of starting Aquatics habitats. The number of infected humans varied also from 0 to 90 which led to a total of 1001 simulations.

Results: The results show that when the number of houses and AH is equal, we find approximately the same results as the field data. At each reduction of AH, the incidence and prevalence tend more and more towards 0. On the other hand, when there is no AH and infected humans in the environment, the prevalence and incidence are at 0.

Conclusions: The study shows that every time we destroy the AH, it increasingly inhibits the growth of mosquitoes and malaria. But when there is no AH site, even if there are infected people in the environment, the disease disappears completely. Therefore the global destruction of the AH in an environment is to be recommended. Using many parameters in the same model is also recommended.

1. Background

Malaria is one of the most dangerous infectious diseases in humans especially in Africa [1]. According to the World Health Organization (W.H.O.), malaria causes a lot of damage today with more than 219 million cases in 2017 worldwide, the majority of cases come from Sub-Saharan Africa [2].

1
2
3
4
5
6 Among the most widely used malaria control measures in Africa, we find mainly:
7 larval source management (LSM) and insecticide-treated nets (ITN) [3]. We note
8 that despite all the efforts made to reduce or eradicate this disease, it continues to
9 persist. Therefore it is important to bring new tools to fight against malaria. How-
10 ever, LSM notably played a very large role in reducing the incidence of malaria [4].
11 Among LSM methods, targeted source reduction (TSR) is the one that researchers
12 precaunize much more than others [3] [4]. Indeed, according to several recent stud-
13 ies, TSR is more precaunized because it is more effective and less expensive [3].
14 However, TSR is contraried because they just treat a part of the AH while ne-
15 glecting the other in a given environment. However, neglected other AH can make
16 malaria reappear [4] and the disease will persist in the area. By knowing the num-
17 ber and speed of mosquito reproduction [3], even if there are few mosquitoes in an
18 area, in a short time the number of mosquitoes will grow at a rapid rate. Do not
19 also forget that mosquito can fly up to 10 - 12 km overflight during its lifetime
20 with a speed of 1.6 - 2.4 km/h [5] and can live up to 40 days [6]. Depending on the
21 houses of humans, larval development may be accentuated thereby increasing the
22 number of mosquitoes. However, for the control of malaria, TSR are increasingly
23 recommended. We can see that TSR is not a better method for Africans, since
24 wastewater is a potential breeding ground for mosquitoes. This wastewater also
25 comes out every day because it is part of actions linked to the habits of Africans.

26
27 Today, environmental management (EM) has taken Aquatic Habitat Management
28 (AHM) of mosquitoes from new angles. First, new EM tools are being implemented
29 and are costing more and more less. We could for example mention aerial spraying
30 through drones or planes [7]. Thus, rather than going into the field to spray, we
31 can use aerial rain by using products that are not harmful to humans such as new
32 formulas of pesticides or biopesticides for example [7]. However, the side effects
33 on humans of spray products pose a major challenge. We realize that treating an
34 entire area can become cheaper and take less time compared to going down on the
35 ground to spray or destroy aquatic habitats of mosquitoes [8]. The overall treatment
36 of an area requires a good understanding of the production and effectiveness of
37 control measures for the entire area. Second, communication tools can be used
38 to sensitize the population and also promote environmental sanitation to avoid
39 the production of AH as much as possible around houses [9] [10] [11]. Reduce the
40 breeding grounds can prolong the development of the gonotrophic cycle and the
41 spread of malaria [3]. The life cycle of the female anopheles consists of two phases:
42 a laying phase (the mosquito searches for a lava site for the laying of eggs) and
43 development and a phase of searching for blood in a host. Search oviposition sites
44 and hosts can have important implications for the spread of malaria. The female
45 mosquito cycle (egg-laying and blood-feeding) can help us to deny mosquito to have
46 an opportunity to reduce the blood feeding's frequency and egg-laying by using
47 these programs. So, mortality over the cycle can be increase. Understanding the
48 dynamic of mosquito help the programs of intervention's development especially
49 to know demarcate, and guide the perimeter of environmental sanitation areas.
50 Nevertheless, taking parameters such as behaviors, movements, gonotrophic cycle,
51 a cycle of malaria in each individual, and the status of individuals in the same model
52 is often not possible. However, the consideration of these parameters in a model is
53 important because it better reflects reality.

The mosquito development cycle is closely related to the evolution of plasmodium in each mosquito. A single bite is not always enough for a mosquito or human to become infectious. Yet most ABMs designed so far consider that a single mosquito bite can transmit plasmodium. Also, the majority of ABMs do not take into account the evolutionary cycle of malaria which would take us from susceptible mosquitoes to latent then infectious and from humans susceptible to recovery via latent and infectious. In this model, we use the questing resting as in Kamgang et al. [12] to represent the number of infectious bites. Also, we use the classes of individuals from the kamgang et al. and Chinit [13] mathematical models to represent the evolution of malaria in each individual.

Representing the number of infectious bites and the evolution of malaria in each individual is complicated because the movements of mosquito are dependent on each status. Although the agent-based models represent the behaviors and habits of each agent individually, it is nevertheless difficult to realize certain phenomena of epidemiology such as the number of infectious bites and the evolution of the disease in each individual. But today, with the development of computing, there are still ABM tools that we can use to represent real-world elements (which were difficult to achieve before) through complex behaviors.

In this work, we take into account: the questing resting to properly define the activities of mosquitoes, the different stages of the disease to know the evolution of the disease in each individual, the different stages of mosquito development namely the immature (egg, larva, pupa) and adult phase to follow the individual development of individuals, the daily activities of individuals. We develop an ABM to simulate development and malaria evolution in each individual. We also simulate the activities, life cycle, status, and movement of each female individual in the heterogeneous landscapes. Our study's objective was to assess and examine the impact of mosquito's aquatic habitat destruction program and also bring out guidelines for LSM by aquatic habitat destruction. The rest of the paper is organized as follows: section 2 presents material and method; section 3 presents the different results; we discuss in section 4 and section 5 concludes the paper and gives the future work.

2. Methods

2.1. Landscape

From the satellite image, we have circumscribed the Demgoya's grouping (figure1) in Cameroon, then target 30 houses. We transferred the data obtained into Qgis software before importing everything into the GAMA platform. We have also located 30 AH around each house, the distance of which varies between 1 m and 400 m from the associated house see figure 1. This reflects the environment and typical behavior of African villages [3]. Indeed, in African behavior, households generally pour dirty water not far from their homes which creates a small AH around the houses. Each house is inhabited by at least two humans and at most 5 humans as in [3]. As in [3], All aquatic habitats and houses were supposed to have the same mosquitoes' attractiveness. The area of our grouping is estimated at 242.99 km^2 .

In this work, the research of the host and the egg-laying depend entirely on the position of mosquitoes, AH, humans, and houses. This is because the mosquito that is looking for the host (for the blood meal) searches the host or house closest. Also,

after taking a blood meal, the mosquito searches for the nearest AH within its radius of flight for the laying.

2.2. From eggs to immature adult mosquitoes

Since mosquitoes have four phases (one adult phase and three aquatic phases: egg, larva, lymph) of development [6], we model the transition from one phase to another according to a certain constant rate (table 1). We set the maximum laying threshold at 5000 eggs/habitat as done by Gu et al. [3]. We set the eggs, larva, and lymph to 0 at each initialization. At each simulation step, when an adult mosquito has all its resources for egg-laying, it lays between 1-80 eggs per oviposition in a nest chosen from among those within its range. The migration of mosquitoes is not taken into account. This laying depends on the probability of laying which is also constant. We also fix the death probabilities of eggs, larvae, pupa, and adults (table 1). After laying, the eggs have the possibility of becoming adult female mosquitoes after having gone through all the aquatic phases.

2.3. Adult mosquitoes

For each mosquito, we followed the movement and the life cycle as did GU et al [3]. We also add for each adult mosquito the cycle of malaria development as in the compartment or mathematical models. In these models, we move from one class to another by rates and times known by epidemiologists. We use the same principle to model the cycle of malaria development in each mosquito. The transition from one class to another is function of a constant rate dependent on the dates of emergence and last blood feeding at each transition (table 1). Note that all mosquitoes newly emerged as adults are considered susceptible. Mosquitoes leave the population through natural mortality or through additive mortality due to activity. We assume that any individual who crosses the boundary of the area is considered dead. To represent the number of infectious bites, we use the questing resting resting model of Kamgang et al. (figure 2). The mosquito performs a random flight within its radius of flight which is 250 m/day as in [3]. The mosquito's hours of activity are between 6 p.m. and 6 a.m. [6]. Adult mosquitoes also have a probability of death depending on their class (see table 1). The normal lifespan of a mosquito is estimated at 40 days [6].

2.4. The human population

In African groups, there are generally not many inhabitants [6], that is why we have considered 30 houses. In these 30 houses, we find the human who spends the whole night (6 p.m. - 6 a.m.) to sleep. We also represent the development of malaria in each human using the compartments or classes of mathematical models in the literature. Deaths are represented by the probability depending on each class (see table 1). We distinguish here men and women to be able to represent births, migration is not taken into account here. Indeed, when a woman is between 15 and 50 years old, she can give birth to one or two children. The maximum lifespan of a human being fixed to 100 years, at the start of each simulation we allocate an age of between 1 to 100 years for each human.

2.5. Transmission and evolution's cycle of malaria

We used susceptible-latent-infected-recovered (SEIR) compartment models to represent the dynamics of malaria transmission in the simulation. For this, we used the compartment models of Chinit [13] and Kamgang et al. [12] to represent the classes of human and mosquito individuals respectively. We have chosen the Chinit model for humans because it takes into account the majority of the individual's classes including the return of the resettles to the susceptible class. The Kamgang et al. model was chosen for mosquitoes because it represents the majority of mosquito classes and takes into account questing-resting. Indeed, the questing resting makes it possible to represent the fact that the mosquito bites a human several times before becoming infected or infecting humans.

The classes of individuals of humans are: Susceptible (s_h), Latent (E_h), Infected (I_h), Recovered (R_h) (see figure 3). When a human is healthy, it is considered that he is susceptible and he becomes latent (or enters the incubation phase) when he receives an acceptable level of plasmodium represented here by a probability also called contact rate as in Chinit. Note that this is only valid when an infected and active mosquito comes into contact with a healthy human. After 15 days in this phase, humans become infectious and can transmit malaria to a healthy mosquito. It is at this level that he seeks the health center to treat himself. If after 100 days [3], he cannot find the health center for treatment (represented here by the cure rate), he dies of malaria, otherwise, he becomes recovered. Between one to three months [14] [15], the recovered becomes susceptible again at a certain rate. The cycle can then start again and this happens on every human. At each initialization, each individual has a randomly assigned class date, that is, 1-100 years for humans and 1-40 days for mosquitoes.

The mosquito classes of individuals are made up of: Susceptible active Sa, susceptible resting (Mosquitoes rests either in a house or in an aquatic habitat) Sr, Active latent 1 (Eva_1), Active latent 2 (Eva_2), Active latent 3 (Eva_3), Resting latent 1 (Evr_1), Latent at rest 2 (Evr_2), Latent at rest 3 (Evr_3), Latent at rest 4 (Evr_4), infectious at rest (which is not in motion) Ir and Infectious active Ia (see figure 2). Likewise, a healthy mosquito is considered as active susceptible if it searches of a resource (aquatic habitat or house) and susceptible at rest when not in motion. When an active susceptible comes into contact with an infected human or recovered, it becomes latent with a certain rate. If the blood dose is necessary for the development of these eggs, he can return to the AH to rest. This is the reason why the mosquito in the model starts from susceptible active to latent at rest. After a certain time (rest period represented here by a rate), the mosquito if it is still alive, switches from the Er_i class to the Ea_i class ($i = 1,2,3$). When a mosquito in the Ea_i class manages to take its blood meal (with speed), it migrates to the Er_{i+1} class. After a certain time spent in the Er_4 class, it migrates to the Ia class and when it succeeds in having its blood meal, it switches from the Ia class to the Ir class; after he returns to class Ia and this repeats for life. For infection rates (mosquito to human infection and vice versa), we used Chinit rates. We take the infection rates of Chinit rather than that for Kamgang et al. because it represents the different links of infections (For example, in Kamgang et al. model there are no recovered but Chinit takes into account the recovered which can also transmit the disease).

2.6. Managing the environment by destroying aquatic habitat

In our environment, we have identified 30 houses, 30 AH, and a health center. Throughout our study, the houses remained fixed apart from the AH which were varied each time. Indeed, our main objective was to destroy the AH of 10% of the number of starting AH to see the evolution of malaria and mosquitoes. The control of our environment has been covered on 30 AH first, then 27 AH, 24, 21, 18, 15, 12, 9, 6, 3, and finally 0 AH. In every initialization, we consider that each AH has on average 5 mosquitoes and these mosquitoes can increase (up to a maximum of 5000 per AH) and decrease (to a minimum of 0) depending on the cycle of life, behavior, activities, or movement and interactions between individuals. This is how at each initialization, when the environment has 30, 27, 24, 21, 18, 15, 12, 9, 6, 3 and 0 AH, we have 150, 135, 120, 105, 90, 75, 60, 45, 30, 15 and 0 mosquitoes respectively. we also vary the number of infected humans from 0 to 90. To be consistent with reality, we compared our results when there is no heel destruction with the results of the field data. Indeed, it is this scenario that reflects the reality on the ground. So by comparing these results, we don't get a big difference.

2.7. Simulation

For the simulation, we took 6 hours as a simulation step to be able to highlight the working hours of our individuals. Also, each simulation evolves over one year, which makes 1440 cycles per simulation. At each initialization of the simulations, we considered 90 humans (with an average of 3 inhabitants per house). But over time each house can have between 2 and 5 inhabitants. For mosquitoes, we considered an average of 5 mosquitoes per AH at initialization. This number varies over time due in particular to births and deaths.

In our simulation, we first take the same number of houses and AH and vary the number of infected humans to 0-90 and report the result. After, we destroy the AH with a rate of 10% of the number of starting AH until rich to 0 AH and vary every time infected human to 0-90. In the end, we had a total of 1001 simulations. When we vary the number of infected humans from 0 to 90, the distribution for other classes of humans does not respect any distribution rate because the interests class is the infected class. For mosquitoes, we distribute the Sa, Sr, Ia, and Ir equitably and each class is equal to 13.33% of the initial number of mosquitoes in each simulation. Likewise, the latent classes (Eva_1 , Eva_2 , Eva_3 , Evr_1 , Evr_2 , Evr_3 , Evr_4) are also distributed equitably each time. Thus, each latent class represents 6.67% of the initial number of mosquitoes.

The simulation was performed in a machine with capacity: 500GB of DD, 4GB of RAM, and an Intel (R) Core (TM) i3-2310M, 2.1GHZ.

3. Results

3.1. presentation of some curves

The following figures show the shape of some curves of the simulation. We just represent the curves of the simulation in the cases where we have: 0 infected human (and 0%, 10%, 50%, 100% destruction of AH), 1 infected human (and 0%, 10%, 50%, 100% destruction of AH), 9 infected humans corresponding to 10% of the initial number of humans (and 0%, 10%, 50%, 100% destruction of AH), 45 infected

humans corresponding to 50% of the initial number of humans (and 0%, 10%, 50%, 100% destruction of AH), 90 infected humans corresponding to 100% of the initial number of humans (and 0%, 10% , 50%, 100% destruction of AH). We also present some curves on the mosquito population, in particular in the following cases: 0 infected human and 10% AH destruction; 1 infected human, 10% and 100% AH destruction; 9 humans infected and 50% destruction of AH; 45 infected humans, 50% and 100% AH destruction.

3.2. Our results and those of the field

The simulation which corresponds to the normal situation in the field is when we destroy 0% of AH meaning the number of AH is equal to 30. So, when we simulate without destroying the AH, we find almost the same prevalence and incidence as those in the field. Thus, field data show that the prevalence is equal to 1.999% and the incidence is equal to 1.938%. When the number of AH is equal to 30, the prevalence varies from 1.159% (corresponds to the case that the initial number of infected is 0) to 2.057% (corresponds to the case that the initial number of infected is 90). Incidence varies from 0.936% to 1.145% (corresponds to the case that the initial number of infected is 0 90 respectively).

Noted that The prevalence and incidence in the grouping are low because the data was collected on the basis of patients attending the health center in the area. It should be noted that in African grouping, population doesn't visit health centers regularly because they prefer traditional treatment.

3.3. Impact on the wealth of infected mosquito

Mosquitoes are more numerous when there is more AH in the environment. This is explained by the fact that the resources available for the development of mosquitoes are necessary. On the other hand, when there are few AH, mosquitoes no longer have enough resources for their development. For example, we can see in Figure 24 that throughout the simulation, the total number of mosquitoes does not exceed 18 and the number of infected mosquitoes does not exceed 11. This is explained by the fact that in the environment, there are no infected humans and the initial number of mosquito is only 5. So the probability of infected mosquito is low because all humans are healed. The same thing is seen in Figures 25 and 27. Worse, when there is no AH in the environment, we do not find any infected individuals. On the other hand, figures 26, 28, and 29 show that mosquitoes are abundant in the environment. Figure 29 for example shows that the total number of mosquitoes can exceed 300. This can be explained as follows: as there are more than 15 AH and consequently more than 75 mosquitoes at the beginning, then there is a high chance that certain mosquitoes lay and develop their eggs. Indeed, even if in the model mosquitoes have many obstacles (death, death due to activity), some will still obtain resources for egg-laying and development.

Table 2 shows that the entomological inoculation rates (EIR; the number of infected mosquitoes divided by the number of persons) increases in the same way as incidence and prevalence.

3.4. Impact on the transmission of malaria

The transmission of malaria is strongly influenced by the presence of AH in the environment. Since the presence of AH attracts mosquitoes, more there are AH more mosquitoes exists. Thus, the incidence of malaria also changes with the number of individuals infected. Let us observe for example figures 18 and 19 then 28 and 29 (figures which describe respectively the same initial scenarios). We see that there are a lot of infected individuals and high malaria incidence.

3.5. Effect of the destruction of Aquatic Habitats

The table 2 presents malaria incidence and prevalence when the initial number of infected humans is 20 and 0. The table shows that more AH are destroyed, more incidence and prevalence tend more and more towards 0. On the other hand, when there is no AH and infected humans exist in the environment, the incidence and prevalence are evaluated only on those initially infected humans because this number of infected remains constant until the end of the simulation. Finally, if there are no AH sites and no infected humans in the environment, the incidence and prevalence are 0.

3.6. Evolution of individual class according to the destruction rate of aquatic habitat

Looking at Figures 4, 8, 12, 16, and 20 in section 3.1, when all AH are destroyed, the population evolution is normal. Indeed, these figures show that after a certain time, the entire human population tends to be susceptible. On the other hand, even if there is only one AH in the environment, most humans living in that environment are recovered. This means that every human has at least once been achieved with malaria. This can be seen through figures: 5, 6, 7, 9, 10, 11, 13, 14, 15, 17, 18, 19, 21, 22 and 23 of section 3.1.

4. Discussion

Three important results emerge from our work. First, treating just a few aquatic habitats in one environment and leaving others behind is not helpful. Indeed, whether we use the targeted reduction technique or the overall reduction technique with 2 km of perimeters (as in recent studies [3]), we just reduce the incidence of malaria but we do not return it to 0. This means that malaria will go away for a certain time but come back later if the treatment is not done regularly. Our simulations show that it is when we destroy all the AH in an environment that we can greatly reduce the development cycle of the mosquito, hence the eradication of malaria. Indeed, by destroying AH, the mosquito no longer has a place to lay the eggs, lava development, and a place to rest. However, large-scale treatment poses a problem of resources, cost, and timing. If you want to do a large-scale treatment, you need a lot of materials to do it which will give rise to a lot of expenses. The timing is important here because if the overall treatment is not done simultaneously, there is a good chance that mosquitoes from an untreated area will migrate to areas already treated. But these problems could still be addressed using new environmental management mechanisms such as the use of drones. This also poses another problem: the effect of the products to be used on the hosts (humans and animals).

Second, it is important to destroy only mosquitoes that cause malaria. Destroying all mosquitoes can have a lot of impact on the ecosystem as many species feed on mosquitoes [6]. Starting from the fact that not all mosquitoes species are blood-sucking (just 6% [8]), we could thus eliminate only those who seek the host for their blood meal. However, the question of adopting a product that kills only certain species of mosquitoes without a primary and/or secondary effect on the other species remains.

Third, sensitize the population and find ways to sanitize these areas can be the main control measure. Using the two results of the struggles listed above will be useless if the populations continue to follow their habits. Indeed, if the population continues to pour wastewater close to homes, this could allow mosquitoes to continue their development (human and aquatic habitats are available). In addition to sensitization, it will also be necessary to think about cleaning up their environment by channeling wastewater. However, there is a major challenge in the techniques of sensitization and sanitation. Indeed, most African areas, especially those in the South Sahara, are enclosed [16] and difficult to access [16], hence the issue of sensitization and sanitation remains unresolved. But, a draft of a solution can be brought within the sensitization in particular by using the means of communication which exist more and more nowadays (example: social networks, proximity radio, communicating to the population through their leaders traditional, . . .). This communication or sensitization can also be used to show the simple and easy techniques of wastewater sanitation and/or pipes to the populations.

In this model, the distance that mosquito covers between its aquatic habitat and a human house played a major role in the mosquito's ability to obtain resources. Unfortunately, the distance at which mosquitoes can find a certain resource is poorly understood. Recent studies show that mosquito can fly 200-400 m per day. Also, a mosquito can fly up to 10-12 km during its lifetime. From these results, our model shows that if we remove just a few AH, an infected mosquito can contaminate an environment having a surface which range is more than 10 km^2 of its AH. Thus, the disease can be prolonged in the environment if only a few AH are destroyed. This result suggests that forbearing mosquitoes from their resources can severely limit their development and growth around AH.

We have found that resource searching is related to a mosquito flying over distance. Indeed, after mating, the mosquito seeks humans for the blood meal to mature these eggs. After the blood meal, mosquito looks for a place to lay and develop its eggs. Knowing that mosquito can daily travel 200-400 m, destroying the AH would make that mosquito couldn't easily find a resource. So, increasing the flying over's distance of mosquito out of their resources for egg-laying and maturation of eggs could greatly slow down or completely reduce the number of mosquitoes. Mosquito flight and its foraging are influenced by the disposition of resources in the environment.

Given the relentless fight against malaria in Africa, it is important to propose a new direction in the techniques of the fight. It should be noted that our fight does not fall only on the fight by larvicides, but also on the environmental sanitation through the pipeline and sensitization of the populations on the management of domestic waste and wastewater from their household. Although treating water may

help to reduce the development of hematophagous mosquitoes, but does not help the ecology. To help humans on the fight against malaria and ecology in the preservation of certain species, it is important to operate only on hematophagous (that feed on blood) mosquitoes since they are only a minority (6%) [8]. So to be able to operate on these species only, we suggest to the governments to sensitize their populations on the management of their environment. This can be done for example by using the means of communication that exist today to give the building plans even to those living in the deep villages. Also, the canalization of wastewater used by households and domestic waste can be resolved by proposing the methods which use the means adapted to Africa. We can also focus studies on products against mosquitoes that would only operate on hematophagous species without having effects on humans, other species of mosquitoes, animals, and other insects.

Agent-based models are used to understand complex phenomena such as the transmission and spread of malaria. We use this to understand the dynamics of malaria transmission in a grouping. Since the models often give a lot of uncertainties, we took several parameters into account to bring nearer reality and make models to be more robust. Also, we use the data field in other to not go away from reality.

5. Conclusion

In this paper, ABM was proposed to assess and examine the impact of mosquito's AH destruction program and also bring out guidelines for LSM by AH destruction. We have noted that several studies have worked in this domain and find good results but neglecting certain aspects or parameters in their model. We have therefore solved this problem by taking in our model many parameters: questing resting, the different stages of the disease, the life cycle of the mosquito, the daily activities, heterogeneous landscapes, status, and movement. It emerges from this study that makes global destruction is great than TSR. Also, the use of many parameters in the same model makes the model more robust. To make work even more robust and efficient, in future work, we provide to include associate the use of insecticide net treated associate with the aquatic habitat destruction in other to well understand the behavior of individuals (mosquitoes and host). Other parameters will be added in our model like the activity of humans for example.

Author's contributions

In this model, we take into account several parameters that many ABMs did not take into account until now. Among the parameters that we have: the questing resting of the vectors, the taking into account of the SEIRS classes for humans and SEI for the vectors. Our study's objective was to assess and examine the impact of mosquito's aquatic habitat destruction program and also bring out guidelines for LSM by aquatic habitat destruction. All authors read and approved the final manuscript.

Human model

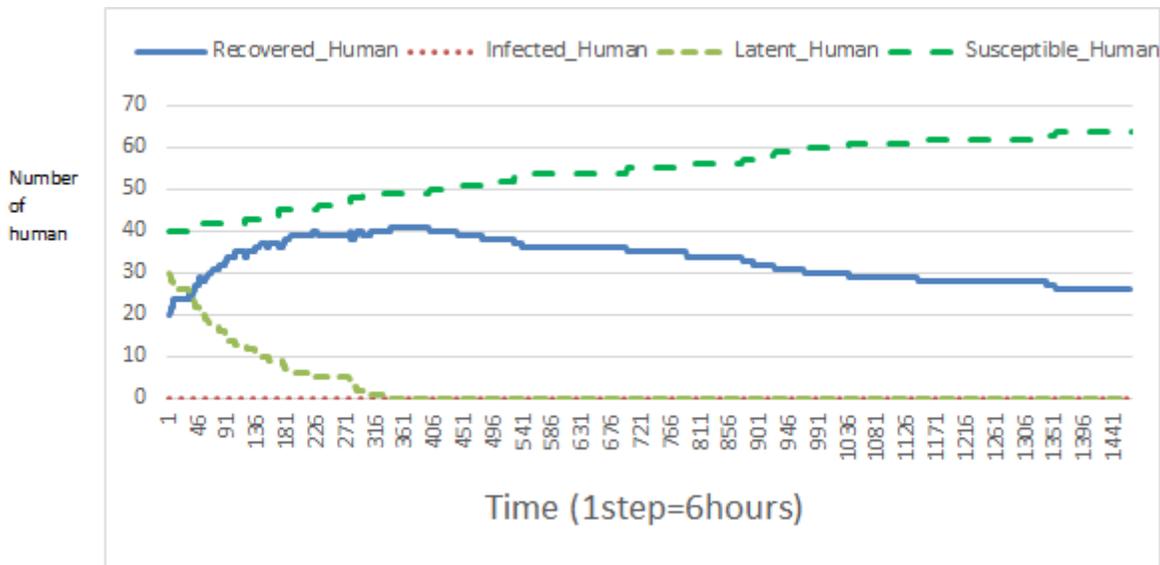

Figure 4

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 0, Number of AH = 0 Sh = 40, Eh = 30, lh = 0, Rh = 20, Sva = 0, Svr = 0, Eva1 = 0, Eva2 = 0, Eva3 = 0, Evr1 = 0, Evr2 = 0, Evr3 = 0, Evr4 = 0, Iva = 0 and Ivr = 0

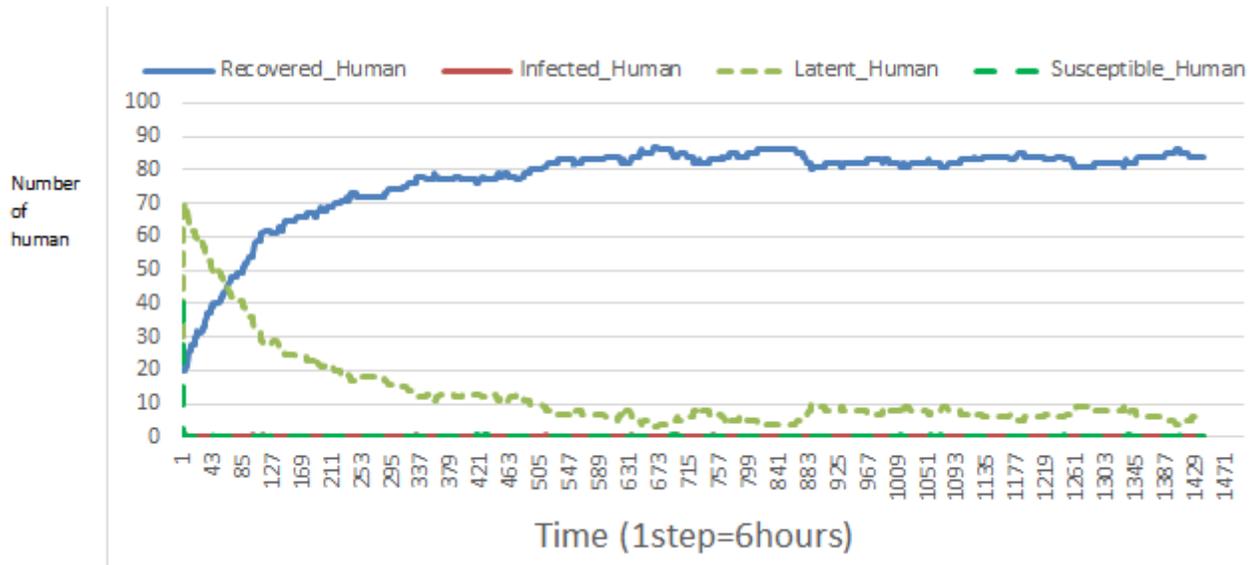

Figure 5

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 0, Number of AH = 3 Sh = 40, Eh = 30, lh = 0, Rh = 20, Sva = 2, Svr = 2, Eva1 = 1, Eva2 = 1, Eva3 = 1, Evr1 = 1, Evr2 = 1, Evr3 = 1, Evr4 = 1, Iva = 2 and Ivr = 2

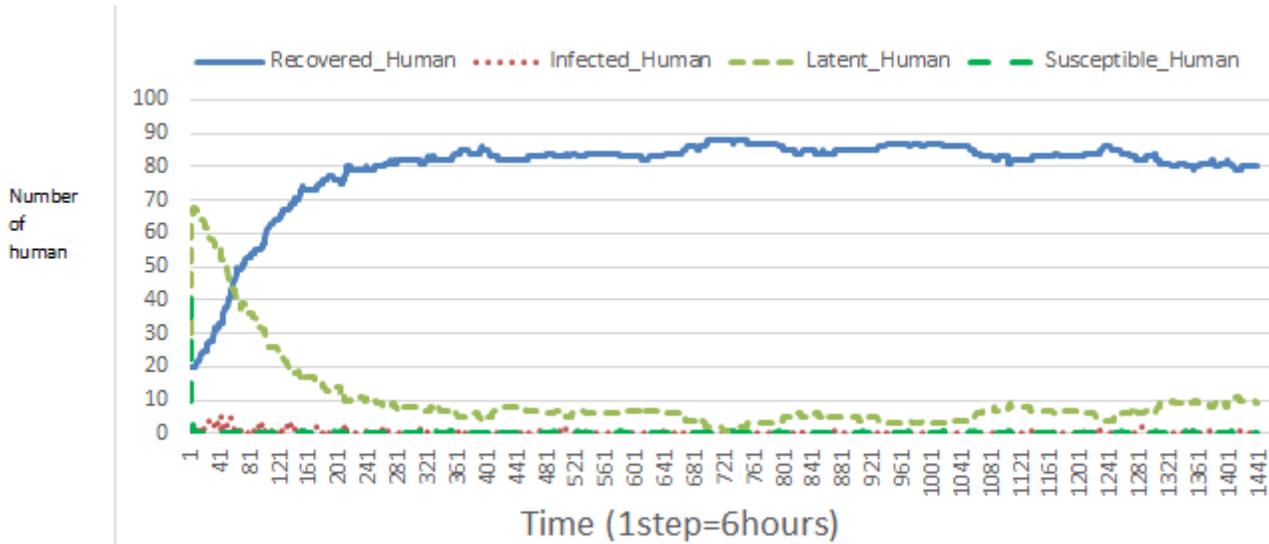

Figure 6

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 0, Number of AH = 15 Sh = 40, Eh = 30, Ih = 0, Rh = 20, Sva = 10, Svr = 10, Eva1 = 5, Eva2 = 5, Eva3 = 5, Evr1 = 5, Evr2 = 5, Evr3 = 5, Evr4 = 5, Iva = 10 and Ivr = 10

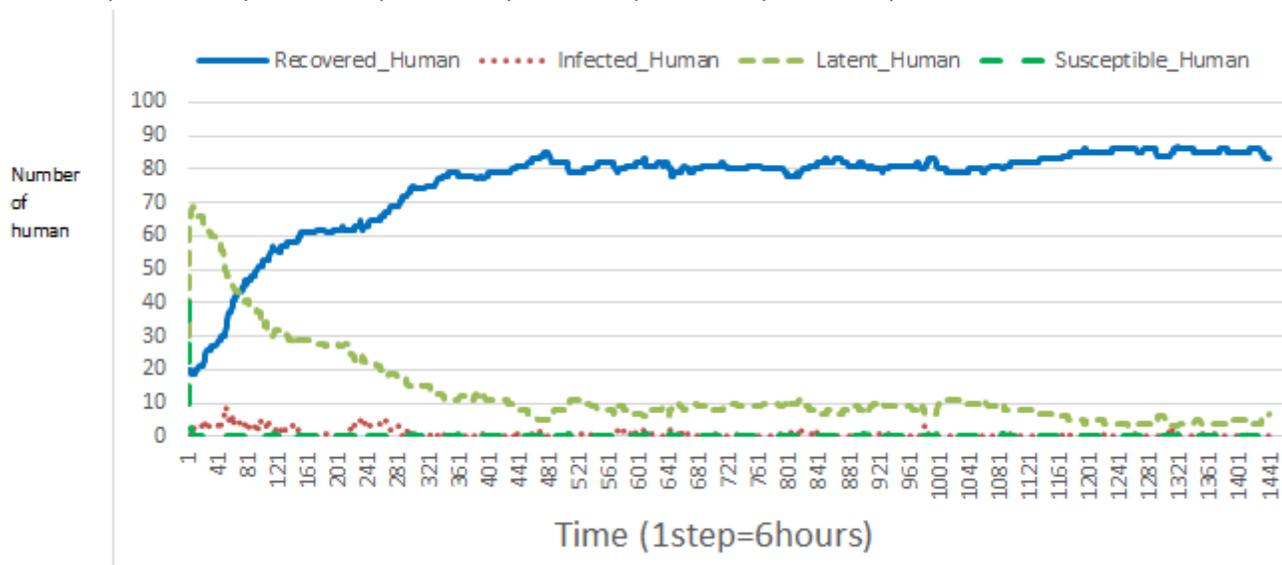

Figure 7

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 0, Number of AH = 30 Sh = 40, Eh = 30, Ih = 0, Rh = 20, Sva = 20, Svr = 20, Eva1 = 10, Eva2 = 10, Eva3 = 10, Evr1 = 10, Evr2 = 10, Evr3 = 10, Evr4 = 10, Iva = 20 and Ivr = 20

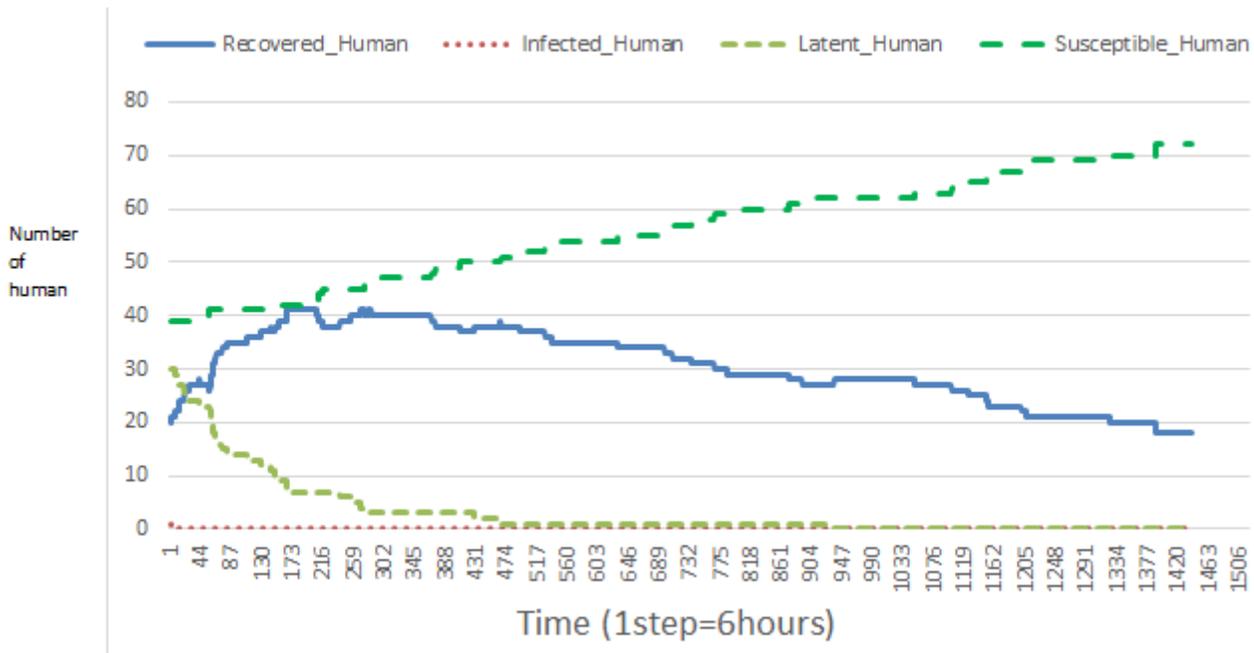

Figure 8

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 1, Number of AH = 0 Sh = 39, Eh = 30, lh = 1, Rh = 20, Sva = 0, Svr = 0, Eva1 = 0, Eva2 = 0, Eva3 = 0, Evr1 = 0, Evr2 = 0, Evr3 = 0, Evr4 = 0, Iva = 0 and Ivr = 0

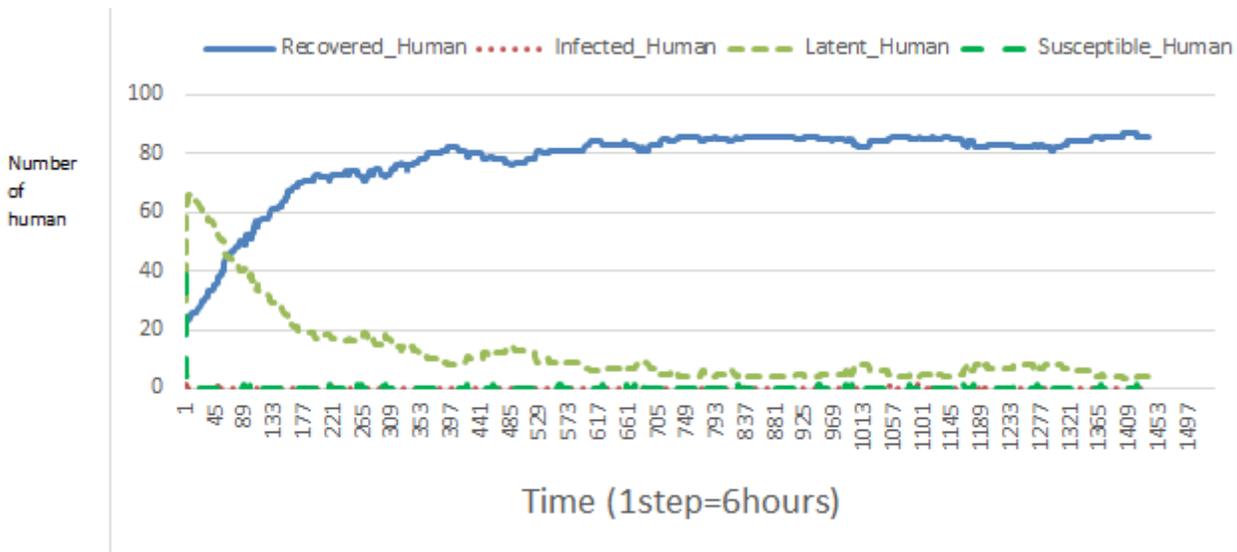

Figure 9

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 1, Number of AH = 3 Sh = 39, Eh = 30, lh = 1, Rh = 20, Sva = 2, Svr = 2, Eva1 = 1, Eva2 = 1, Eva3 = 1, Evr1 = 1, Evr2 = 1, Evr3 = 1, Evr4 = 1, Iva = 2 and Ivr = 2

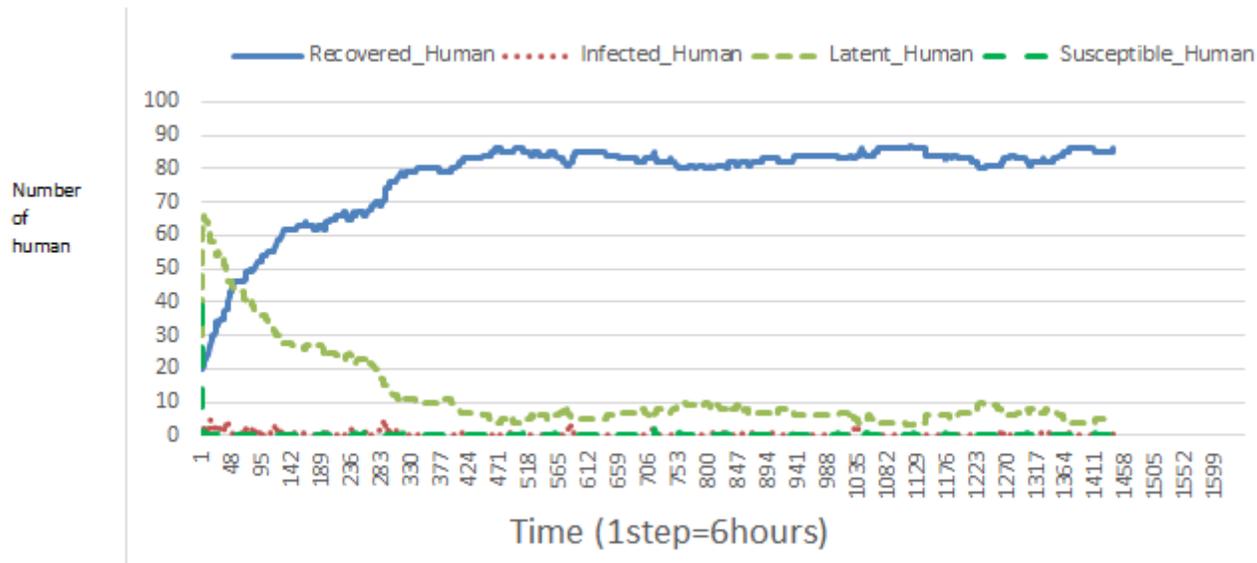

Figure 10

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 1, Number of AH = 15 Sh = 39, Eh = 30, lh = 1, Rh = 20, Sva = 10, Svr = 10, Eva1 = 5, Eva2 = 5, Eva3 = 5, Evr1 = 5, Evr2 = 5, Evr3 = 5, Evr4 = 5, Iva = 10 and Ivr = 10

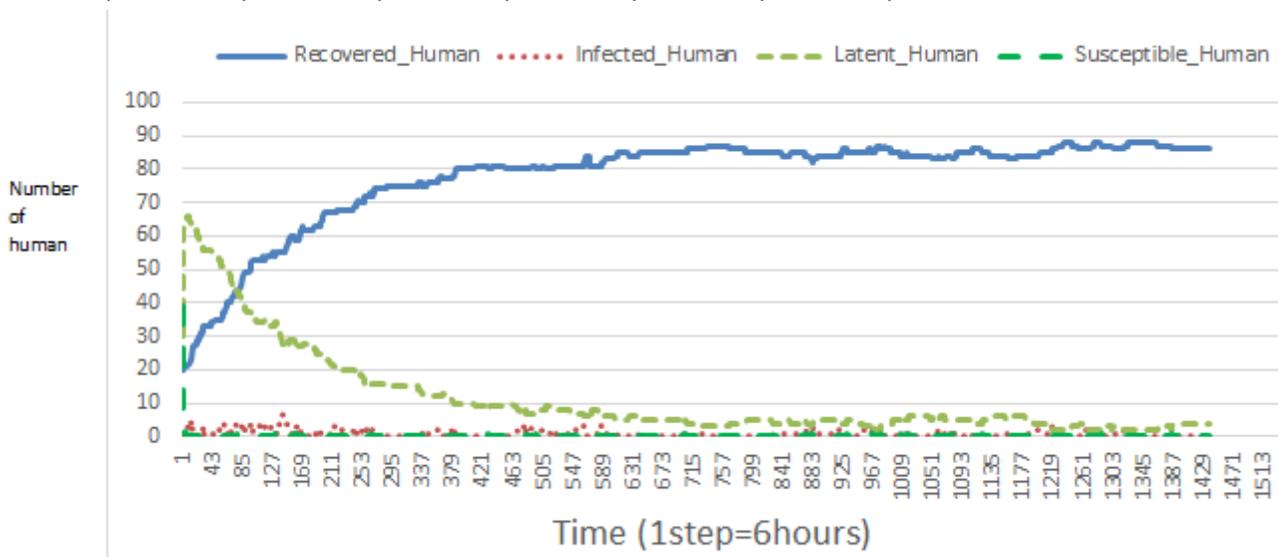

Figure 11

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 1, Number of AH = 30 Sh = 39, Eh = 30, lh = 1, Rh = 20, Sva = 20, Svr = 20, Eva1 = 10, Eva2 = 10, Eva3 = 10, Evr1 = 10, Evr2 = 10, Evr3 = 10, Evr4 = 10, Iva = 20 and Ivr = 20

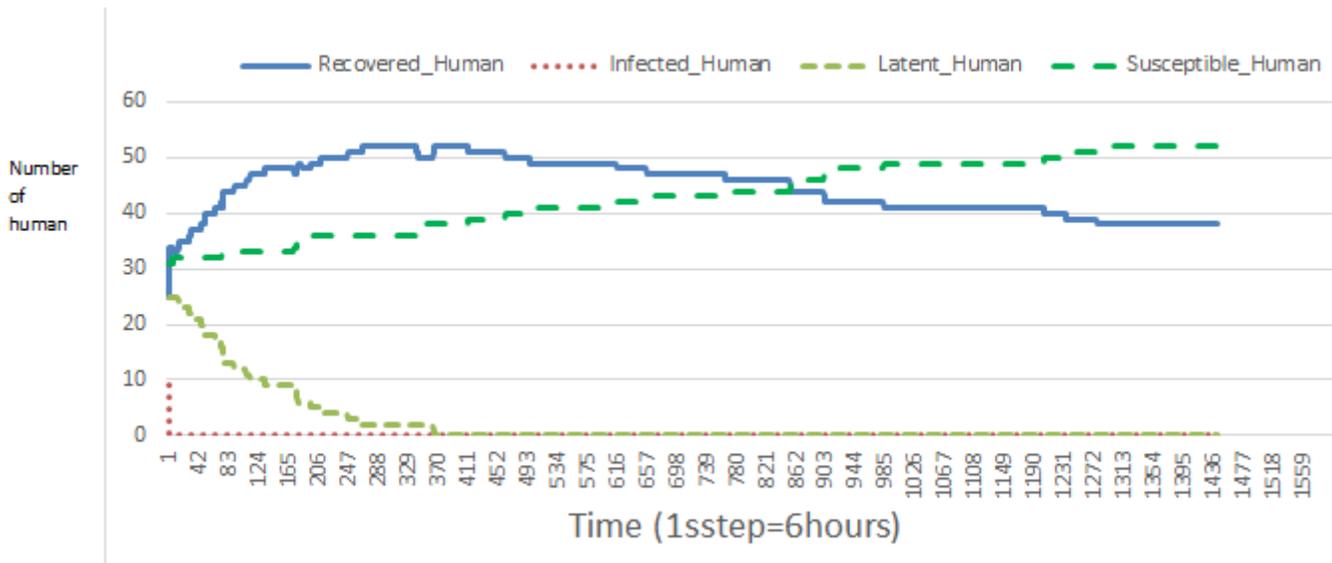

Figure 12

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 9, Number of AH = 0 Sh = 31, Eh = 25, lh = 9, Rh = 25, Sva = 0, Svr = 0, Eva1 = 0, Eva2 = 0, Eva3 = 0, Evr1 = 0, Evr2 = 0, Evr3 = 0, Evr4 = 0, Iva = 0 and Ivr = 0

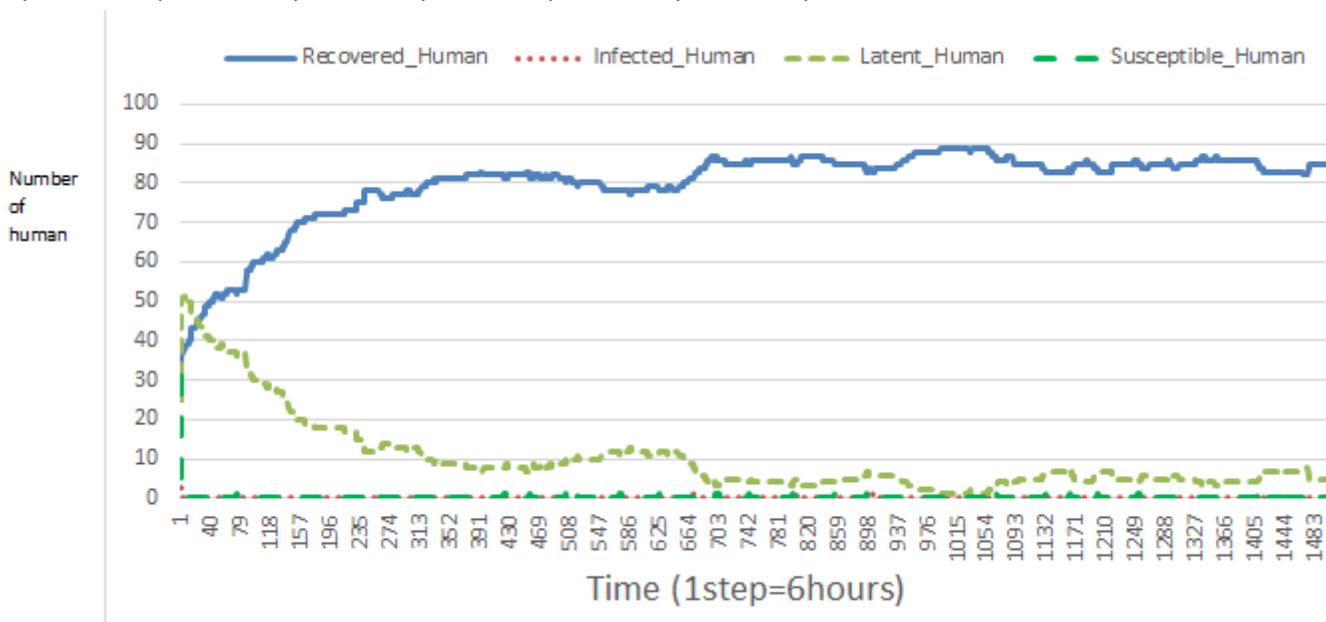

Figure 13

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 9, Number of AH = 3 Sh = 31, Eh = 25, lh = 0, Rh = 25, Sva = 2, Svr = 2, Eva1 = 1, Eva2 = 1, Eva3 = 1, Evr1 = 1, Evr2 = 1, Evr3 = 1, Evr4 = 1, Iva = 2 and Ivr = 2

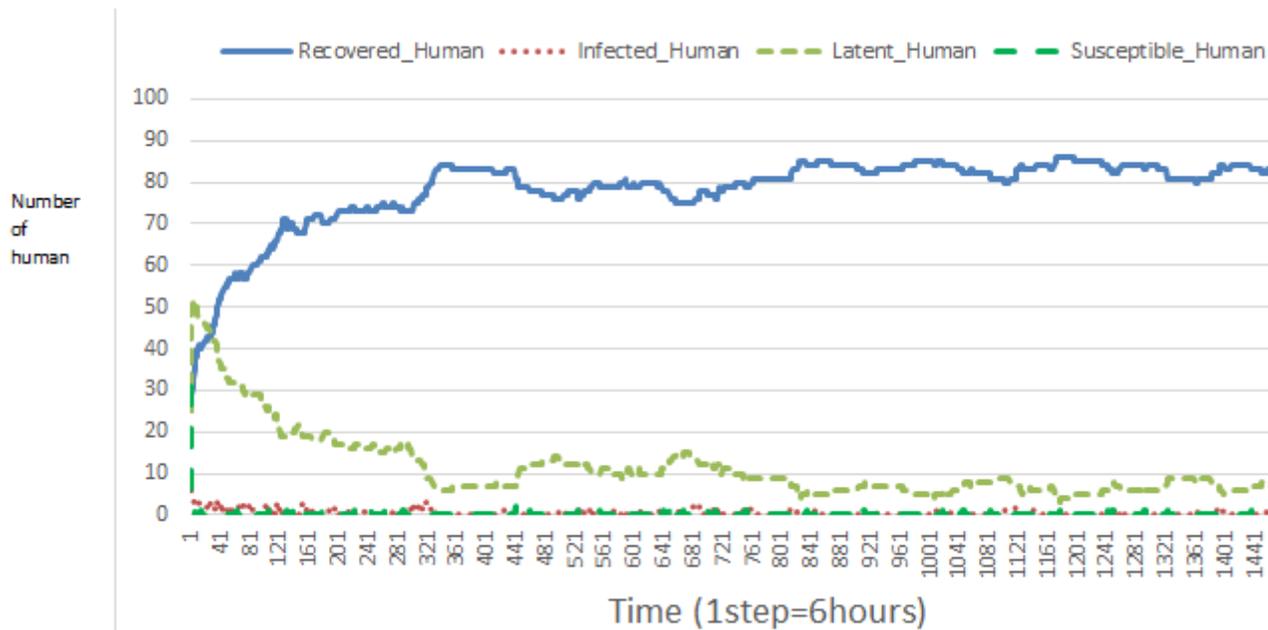

Figure 14

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 9, Number of AH = 15 Sh = 31, Eh = 25, lh = 0, Rh = 25, Sva = 10, Svr = 10, Eva1 = 5, Eva2 = 5, Eva3 = 5, Evr1 = 5, Evr2 = 5, Evr3 = 5, Evr4 = 5, lva = 10 and lvr = 10

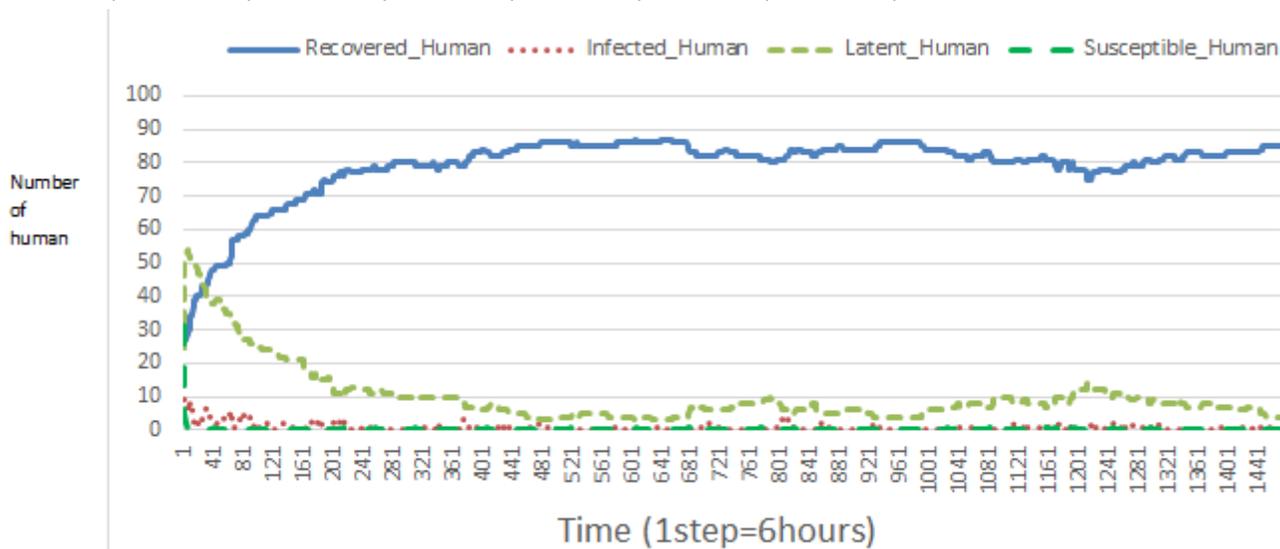

Figure 15

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 9, Number of AH = 30 Sh = 31, Eh = 25, lh = 9, Rh = 25, Sva = 20, Svr = 20, Eva1 = 10, Eva2 = 10, Eva3 = 10, Evr1 = 10, Evr2 = 10, Evr3 = 10, Evr4 = 10, lva = 20 and lvr = 20

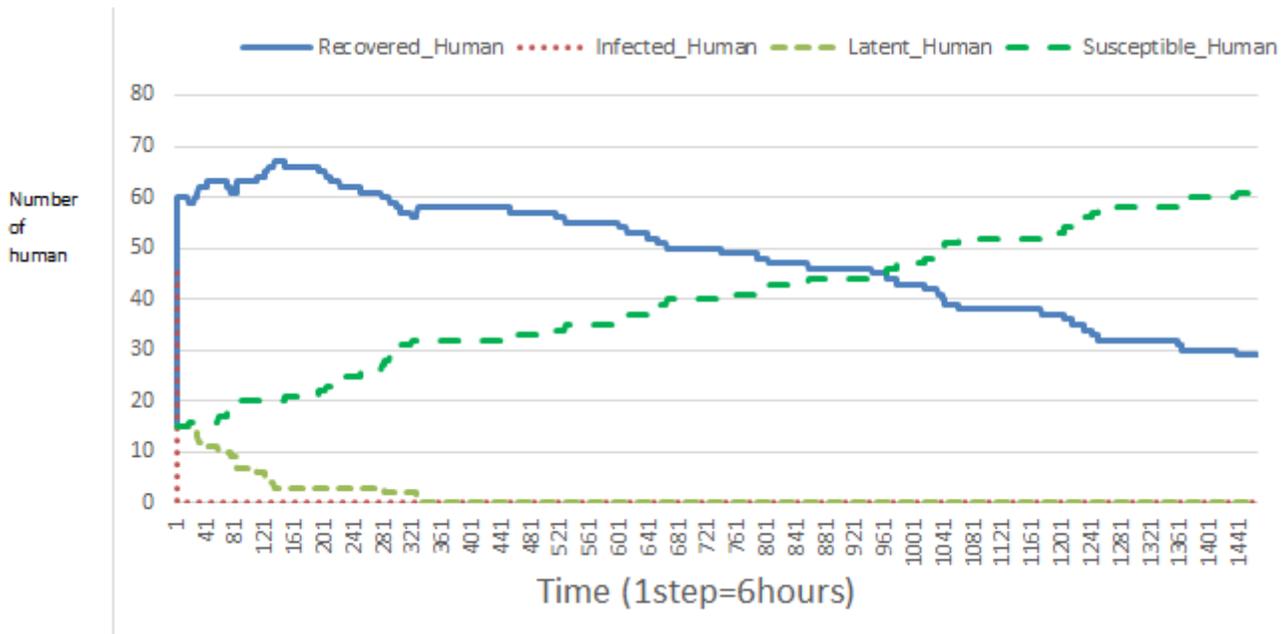

Figure 16

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 45, Number of AH = 0 Sh = 15, Eh = 15, lh = 45, Rh = 15, Sva = 0, Svr = 0, Eva1 = 0, Eva2 = 0, Eva3 = 0, Evr1 = 0, Evr2 = 0, Evr3 = 0, Evr4 = 0, Iva = 0 and Ivr = 0

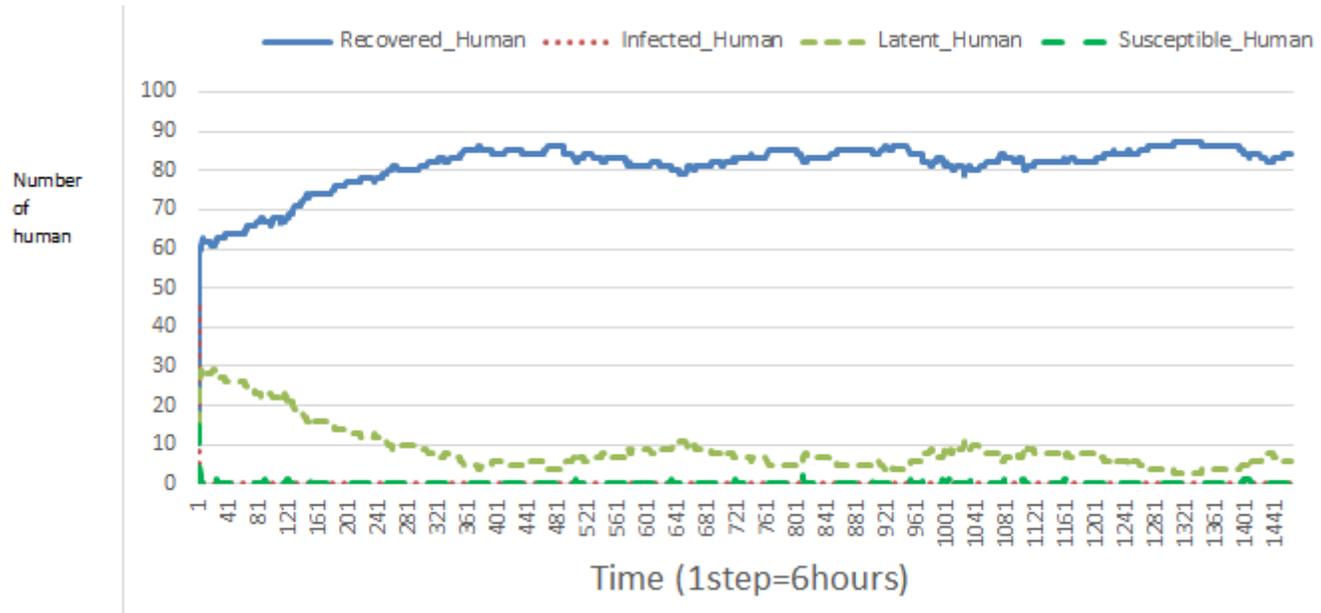

Figure 17

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 45, Number of AH = 3 Sh = 15, Eh = 15, lh = 45, Rh = 15, Sva = 2, Svr = 2, Eva1 = 1, Eva2 = 1, Eva3 = 1, Evr1 = 1, Evr2 = 1, Evr3 = 1, Evr4 = 1, Iva = 2 and Ivr = 2

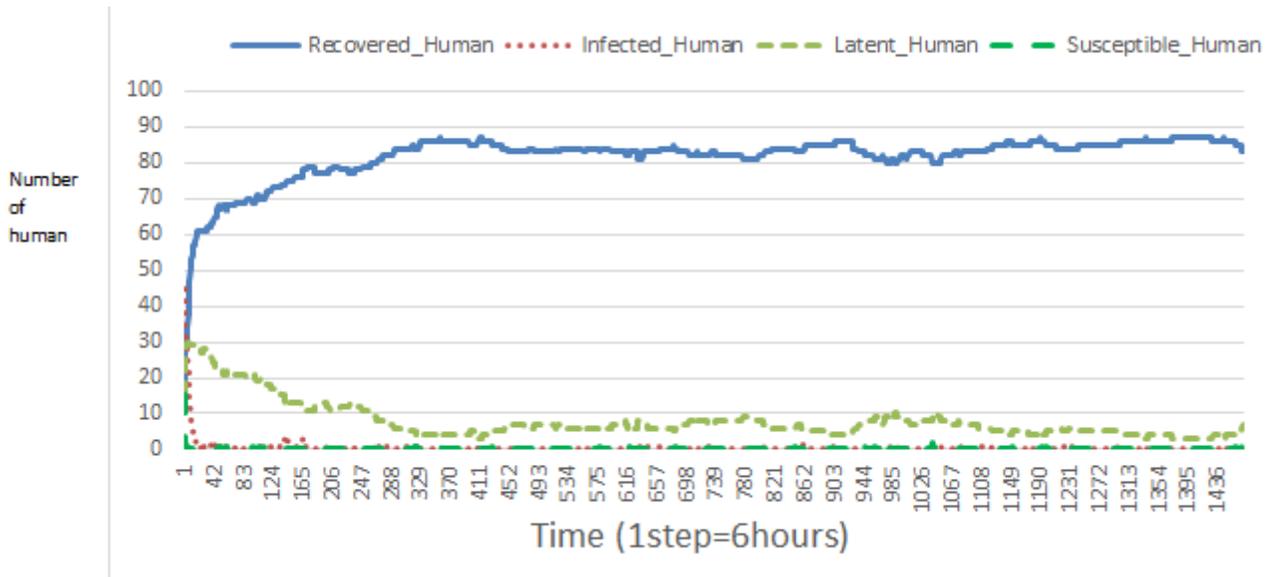

Figure 18

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 45, Number of AH = 15 Sh = 15, Eh = 15, lh = 45, Rh = 15, Sva = 10, Svr = 10, Eva1 = 5, Eva2 = 5, Eva3 = 5, Evr1 = 5, Evr2 = 5, Evr3 = 5, Evr4 = 5, Iva = 10 and Ivr = 10

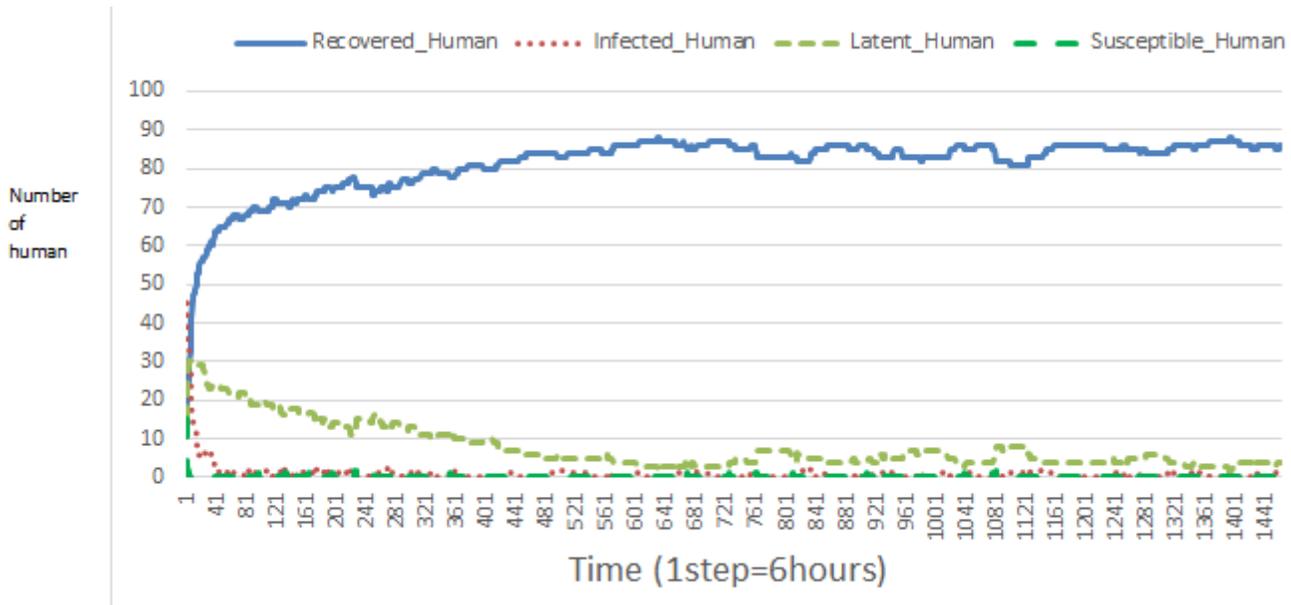

Figure 19

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 45, Number of AH = 30 Sh = 15, Eh = 15, lh = 45, Rh = 15, Sva = 20, Svr = 20, Eva1 = 10, Eva2 = 10, Eva3 = 10, Evr1 = 10, Evr2 = 10, Evr3 = 10, Evr4 = 10, Iva = 20 and Ivr = 20

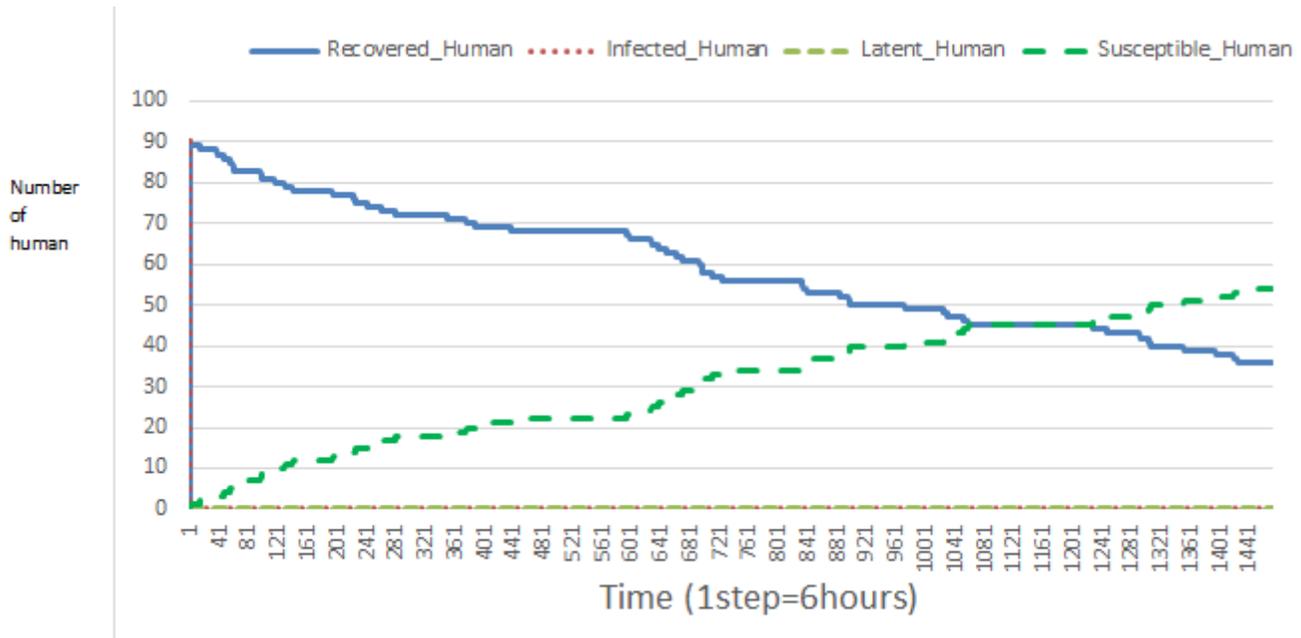

Figure 20

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 90, Number of AH = 0 Sh = 0, Eh = 0, lh = 90, Rh = 0, Sva = 0, Svr = 0, Eva1 = 0, Eva2 = 0, Eva3 = 0, Evr1 = 0, Evr2 = 0, Evr3 = 0, Evr4 = 0, Iva = 0 and Ivr = 0

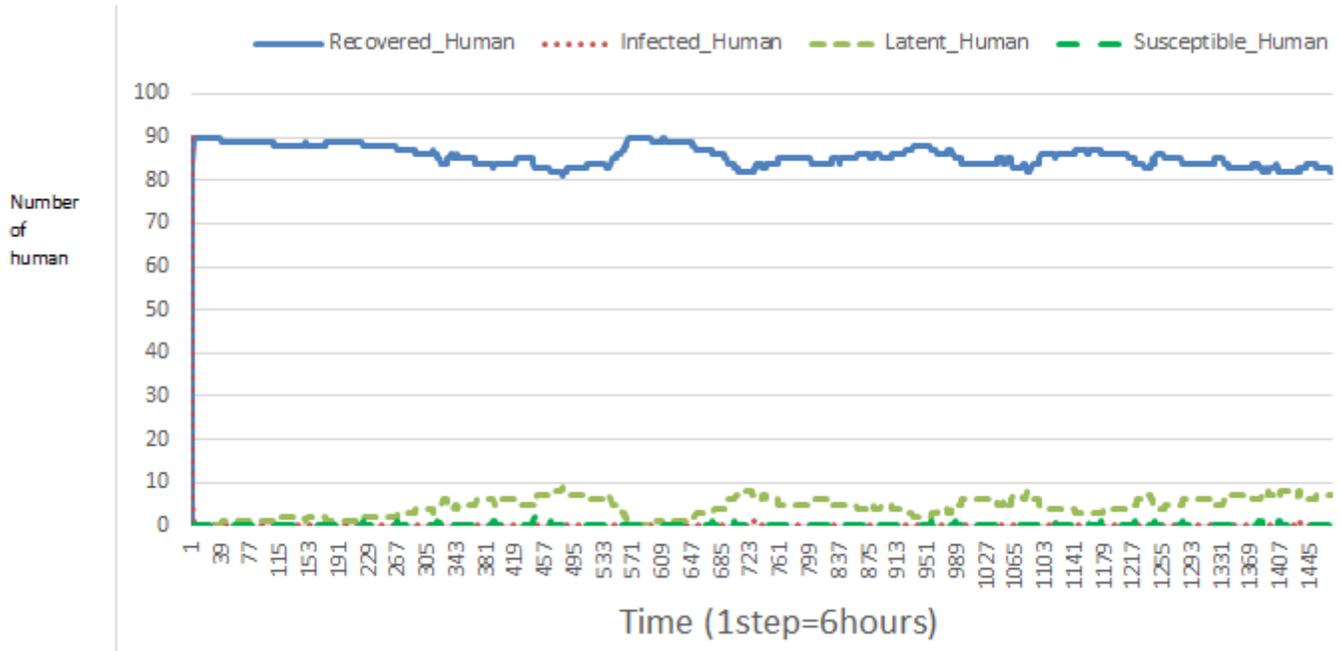

Figure 21

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 90, Number of AH = 3 Sh = 0, Eh = 0, lh = 90, Rh = 0, Sva = 2, Svr = 2, Eva1 = 1, Eva2 = 1, Eva3 = 1, Evr1 = 1, Evr2 = 1, Evr3 = 1, Evr4 = 1, Iva = 2 and Ivr = 2

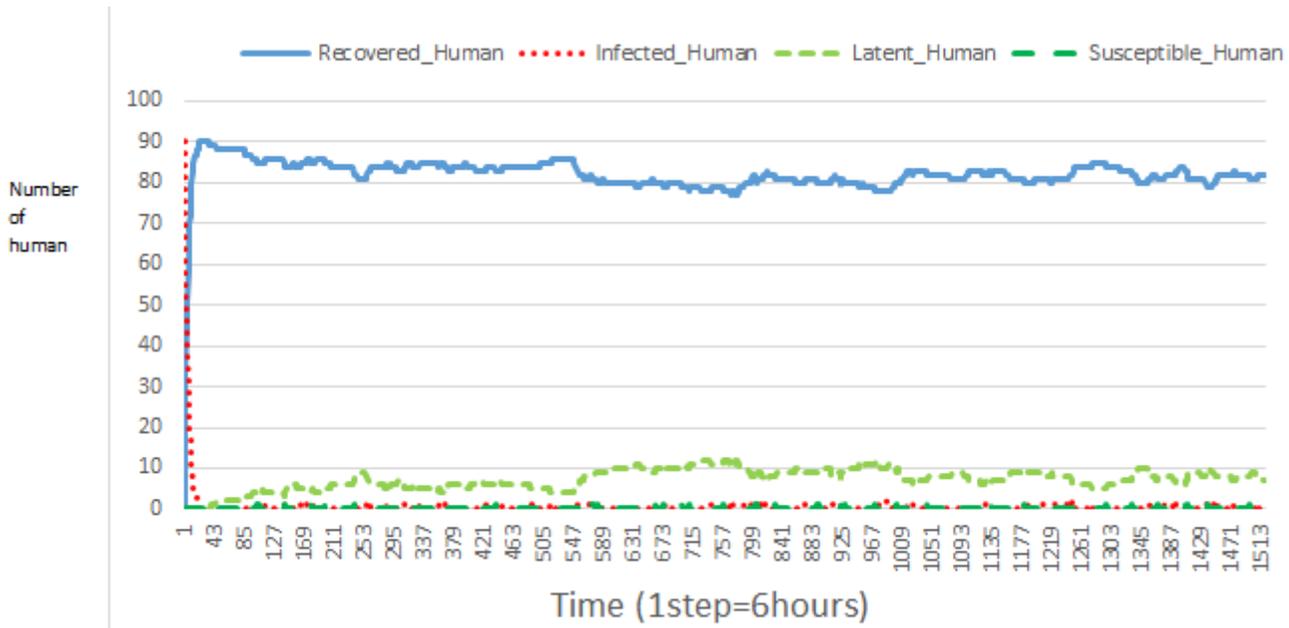

Figure 22

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 90, Number of AH = 15 Sh = 0, Eh = 0, lh = 90, Rh = 0, Sva = 10, Svr = 10, Eva1 = 5, Eva2 = 5, Eva3 = 5, Evr1 = 5, Evr2 = 5, Evr3 = 5, Evr4 = 5, Iva = 10 and Ivr = 10

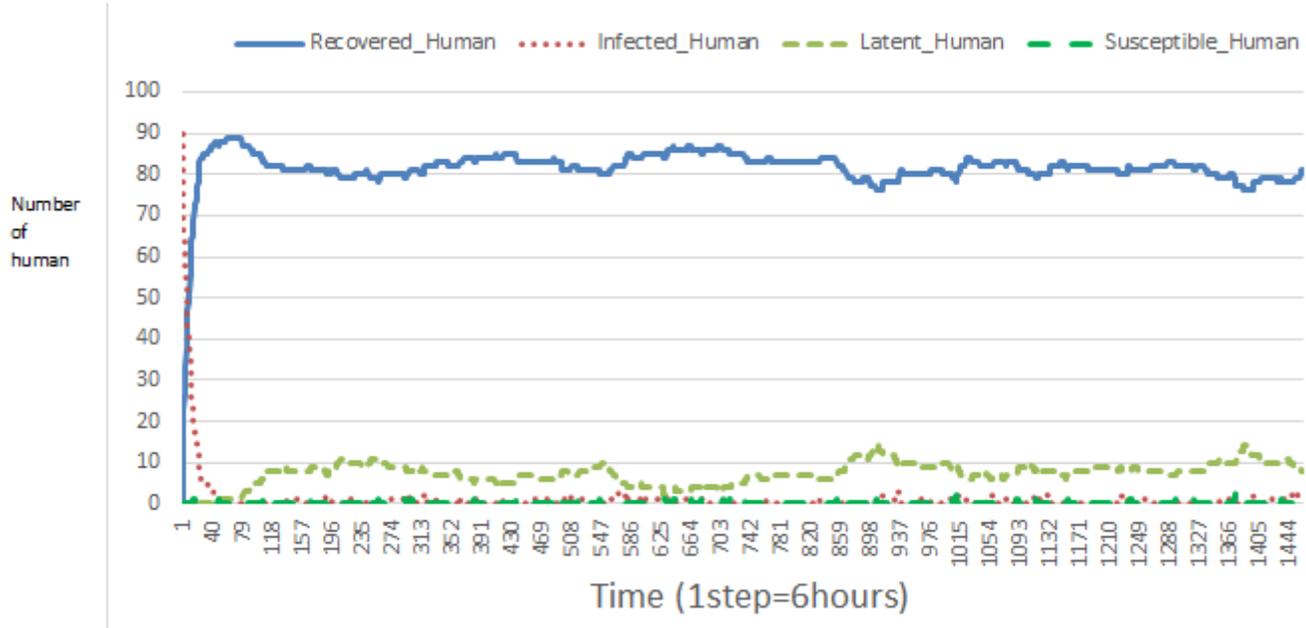

Figure 23

Human population: Evolution of susceptible, latent, infected, and recovery. The initial conditions are: number of infected human = 90, Number of AH = 30 Sh = 0, Eh = 0, lh = 90, Rh = 0, Sva = 20, Svr = 20, Eva1 = 10, Eva2 = 10, Eva3 = 10, Evr1 = 10, Evr2 = 10, Evr3 = 10, Evr4 = 10, Iva = 20 and Ivr = 20

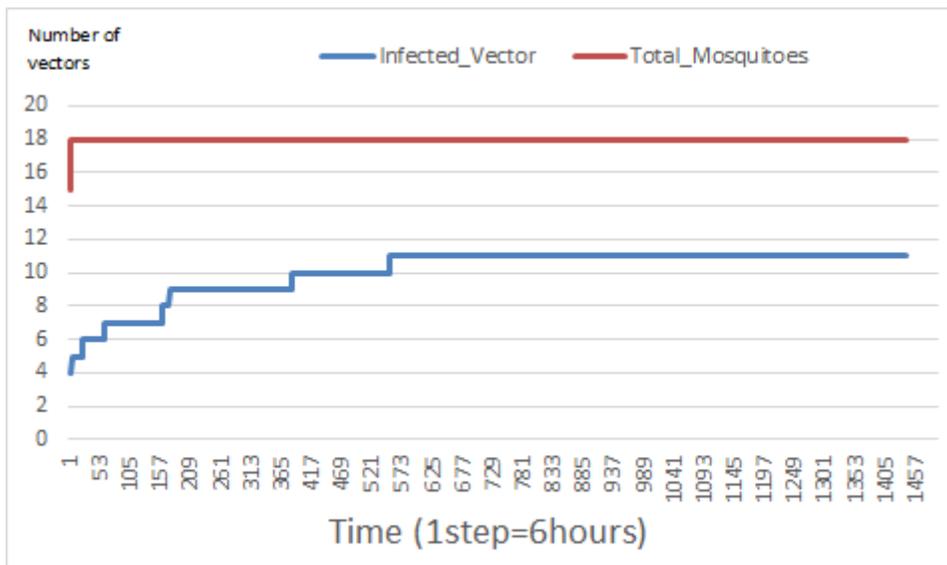

Figure 24

Vector population: Evolution of infected and total Vector. The initial conditions are: $S_h = 40$, $E_h = 30$, $I_h = 0$, $R_h = 20$, $S_{va} = 2$, $S_{vr} = 2$, $E_{va1} = 1$, $E_{va2} = 1$, $E_{va3} = 1$, $E_{vr1} = 1$, $E_{vr2} = 1$, $E_{vr3} = 1$, $E_{vr4} = 1$, $I_{va} = 2$ and $I_{vr} = 2$

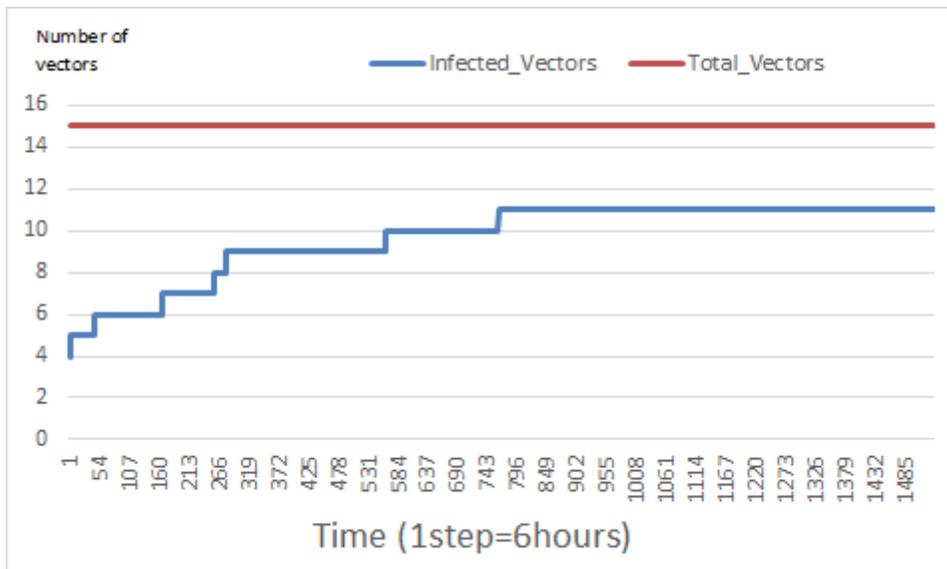

Figure 25

Vector population: Evolution of infected and total Vector. The initial conditions are: $S_h = 39$, $E_h = 30$, $I_h = 1$, $R_h = 20$, $S_{va} = 2$, $S_{vr} = 2$, $E_{va1} = 1$, $E_{va2} = 1$, $E_{va3} = 1$, $E_{vr1} = 1$, $E_{vr2} = 1$, $E_{vr3} = 1$, $E_{vr4} = 1$, $I_{va} = 2$ and $I_{vr} = 2$

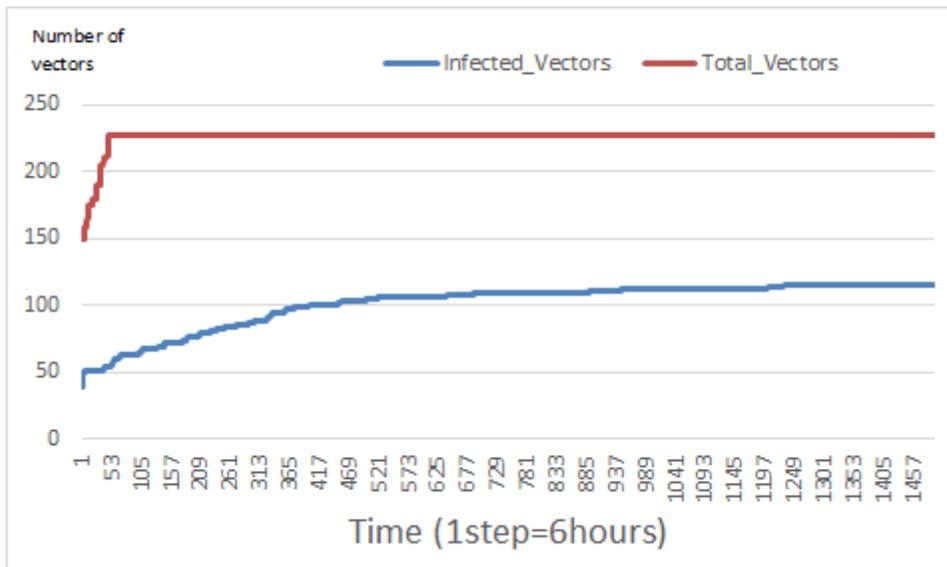

Figure 26

Vector population: Evolution of infected and total Vector. The initial conditions are: $S_h = 39$, $E_h = 30$, $I_h = 1$, $R_h = 20$, $S_{va} = 20$, $S_{vr} = 20$, $E_{va1} = 10$, $E_{va2} = 10$, $E_{va3} = 10$, $E_{vr1} = 10$, $E_{vr2} = 10$, $E_{vr3} = 10$, $E_{vr4} = 10$, $I_{va} = 20$ and $I_{vr} = 20$

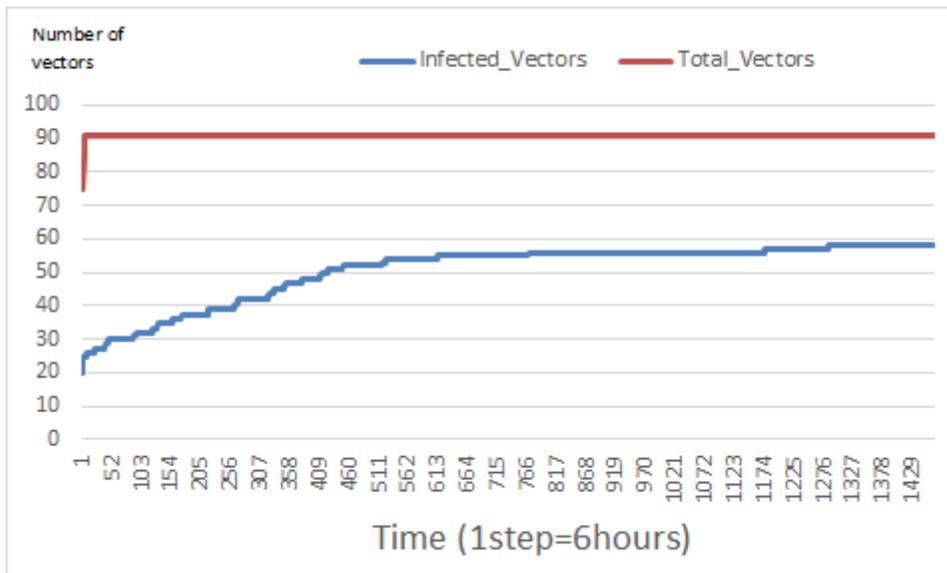

Figure 27

Vector population: Evolution of infected and total Vector. The initial conditions are: $S_h = 31$, $E_h = 25$, $I_h = 9$, $R_h = 25$, $S_{va} = 20$, $S_{vr} = 20$, $E_{va1} = 10$, $E_{va2} = 10$, $E_{va3} = 10$, $E_{vr1} = 10$, $E_{vr2} = 10$, $E_{vr3} = 10$, $E_{vr4} = 10$, $I_{va} = 20$ and $I_{vr} = 20$

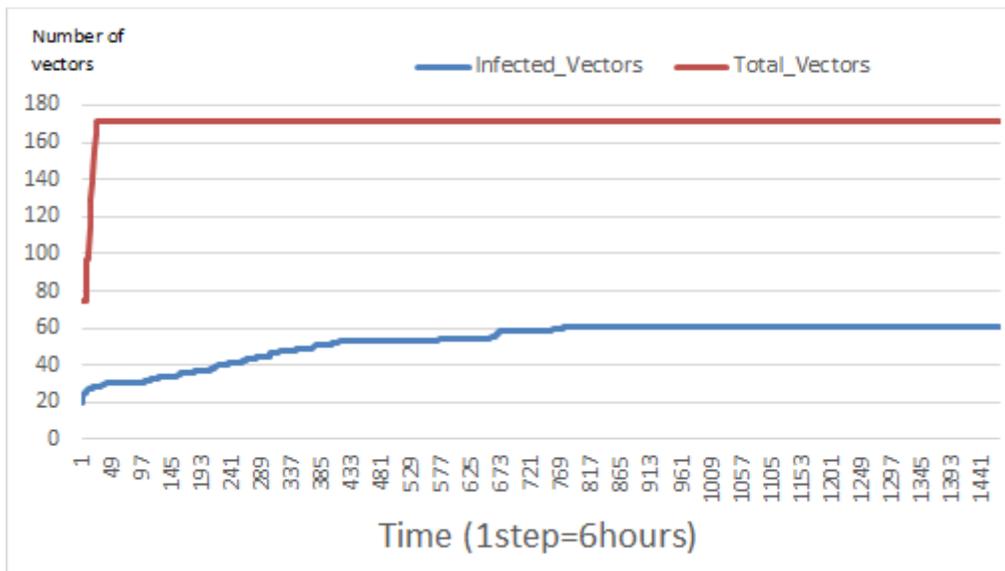

Figure 28

Vector population: Evolution of infected and total Vector. The initial conditions are: $S_h = 15$, $E_h = 15$, $I_h = 45$, $R_h = 15$, $S_{va} = 10$, $S_{vr} = 10$, $E_{va1} = 5$, $E_{va2} = 5$, $E_{va3} = 5$, $E_{vr1} = 5$, $E_{vr2} = 5$, $E_{vr3} = 5$, $E_{vr4} = 5$, $I_{va} = 10$ and $I_{vr} = 10$

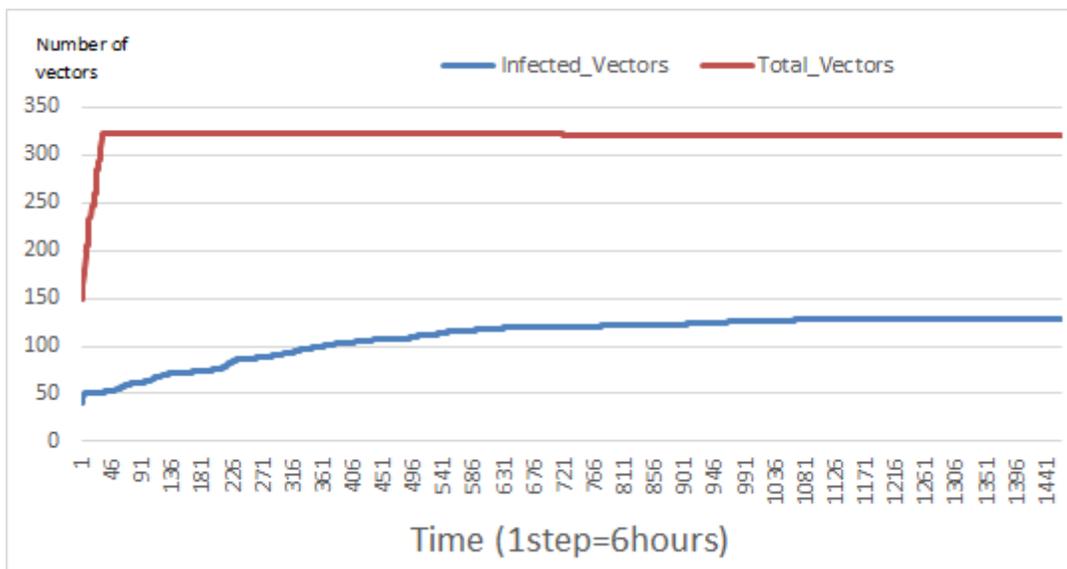

Figure 29

Vector population: Evolution of infected and total Vector. The initial conditions are: $S_h = 15$, $E_h = 15$, $I_h = 45$, $R_h = 15$, $S_{va} = 20$, $S_{vr} = 20$, $E_{va1} = 10$, $E_{va2} = 10$, $E_{va3} = 10$, $E_{vr1} = 10$, $E_{vr2} = 10$, $E_{vr3} = 10$, $E_{vr4} = 10$, $I_{va} = 20$ and $I_{vr} = 20$
