# Vanadium-incorporated CoP$_2$ with lattice expansion for highly efficient acidic overall water splitting

Yu Wang, Yanqing Jiao, Ganceng Yang, Haijing Yan,* Chungui Tian, Aiping Wu, Yue Liu, and Honggang Fu*

**Abstract:** Proton exchange membrane water electrolyzer (PEMWE) in acidic media is a hopeful scenario for hydrogen production by using renewable energy sources, but the grand challenge lies in substituting active and stable noble-metal catalysts. Herein, a robust electrocatalyst of V-CoP$_2$ porous nanowires arranged on carbon cloth is successfully fabricated *via* incorporating vanadium into CoP$_2$ lattice. Structural characterizations and theoretical analysis indicate that lattice expansion of CoP$_2$ caused by V incorporation results in the upshift of d-band center, which is conducive to hydrogen adsorption for boosting HER activity. Besides, V promotes surface reconstruction to generate a thicker Co$_3$O$_4$ layer that enhances acid-corrosion resistance and optimizes the adsorption of water and oxygen-containing species, thus improving OER activity and stability. Accordingly, it presents a superior acidic overall water splitting activity (1.47 V@10 mA cm$^{-2}$) over Pt-C/CC||RuO$_2$/CC, and remarkable stability. This work proposes a new route to design efficient electrocatalysts *via* lattice engineering for PEMWE.

22     Replacing the fossil fuels is of great significance for sustainable energy supply[1,2].

23     Among the various alternatives, hydrogen produced by water electrolysis and

24     renewable energy sources (solar, wind etc.) has been considered as one of the most

25     promising solutions[3,4]. More attentions focus on the conventional alkaline water

26     electrolyzer (AWE), in view of its permission to employ the cost-effective

27     electrocatalysts for cathodic hydrogen evolution reaction (HER) and anodic oxygen

28     evolution reaction (OER)[5,6]. However, due to narrow load range and poor flexibility,

29     it can be only driven by stable thermal power generation[7,8]. Recently, proton exchange

30     membrane water electrolyzer (PEMWE) with easy assembly with renewable energy

31     sources is highlighted as the new-generation candidate, in view of great power density,

32     high efficiency at low temperature and low gas crossover[9,10]. Generally,

33     noble-metal-based materials (Pt and Ir, Ru oxides) are the benchmark HER and OER

34     electrocatalysts in acidic media with high activity and durability, but suffer from high

35     cost and scarcity[11-13]. To this end, earth-abundant transition metal-based materials (e.g.

36     phosphides, chalcogenides, nitrides, carbides etc.) have been developed to accelerate

37     HER and OER[14,15]. Despite gratifying advances have been made in the past decades,

38     the HER performance is still far from Pt in acidic condition[16,17]. Especially in acidic

39     OER process, most of them are unstable in high oxidation potential according to

40     Pourbaix diagrams[18]. Therefore, developing cost-effective and durable HER/OER

41     electrocatalysts in acidic media is crucial but challenging for the large-scale

42     application of PEMWE.

43     Transition metal phosphides, particularly cobalt-based phosphides, have been

44     investigated as promising noble-metal alternatives for HER and OER owing to the

45     high electrical conductivity and noble-metal like properties[19-22]. For instance,

46     Co-phosphides with various stoichiometric ratios show efficient HER activity in

47     acidic, neutral and alkaline solutions[23]. Geyer et al. reported that the catalytic HER

48     activity of cobalt-based phosphides increased with the elevating phosphorous content

49     ($CoP_2$ > CoP > $Co_2P$)[19]. Recently, Co-phosphides also act as OER electrocatalysts in

50     alkaline medium with the characteristic of surface reconstruction to form the

51     corresponding oxides/hydroxides[24]. For example, Xing et al. confirmed CoP nanorods

52  could catalyze OER in 1 M KOH up to 12h, and further verified the good stability

53  was benefited from the generated ultrafine crystalline $Co_2O_3$ layer on the CoP

54  surface[25]. It is shown that Co-oxides can not only stabilize in alkaline media, but also

55  own adequate acid-resistance capacity that can perform a lengthy operation in acidic

56  solution under high anodic potential[26]. Enlightened by above, utilizing the surface

57  reconstruction of cobalt phosphides, the acid-stable OER catalysts may be achieved.

58  To resist strong acid corrosion, the reconstructed oxide layer should be fulfilled to a

59  certain thickness. Although surface reconstruction of pure Co-phosphides will happen

60  naturally during OER electrolysis, the thin surface reconstruction is not enough to

61  resist strong acid corrosion[27,28]. We consider whether any tactics could be adopted to

62  manipulate the surface reconstruction of Co-phosphides and simultaneously increase

63  the thickness of reconstruction layer, thus further improving the OER stability.

64      Heteroatom incorporation has emerged as one of the most effective approaches to

65  improve the intrinsic activities for HER and OER[29,30]. Because heteroatom

66  incorporation can change the crystal environment of host material and regulate the

67  electronic structure, which strengthes the adsorption behaviors of reactive

68  intermediates, thus greatly promoting catalytic activity[31]. Vanadium (V) is an ideal

69  dopant in terms of its abundant resources, variable valence, acid corrosion resistance

70  and adaptive atomic radius close to cobalt[32]. Wang et al. reported V-doped $Co_4N$ with

71  prominent HER catalytic activity due to that V doping tailors the d-band center[33]. Hu

72  et al. designed V "bridge" between Co-O bonds in $CoV_2O_6$ nanowires, which

73  enhances the conductivity, resulting in boosted OER activity in alkaline media[34].

74  Hence, we expect that the HER activity of Co-phosphides can be improved through

75  adjusting electronic structure after vanadium incorporation. Meanwhile, utilizing the

76  positive role of V on Co-phosphides controls surface reconstruction, thus improving

77  the OER stability in acidic media. To our knowledge, studies on this aspect have

78  never been reported.

79      Herein, we fabricated vanadium incorporated cobalt diphosphide porous

80  nanowires on carbon cloth (denoted as $V\text{-}CoP_2/CC$) by a facile two-step method

81  involving hydrothermal treatment and subsequent phosphorization. The lattice

82  expansion of $CoP_2$ caused by V incorporation decreases the overlap of atomic wave

83  functions, leading to upshift of d-band center, which conduces to hydrogen adsorption

84  on P sites for promoting HER. Besides, V promotes surface construction to generate a

85  thicker $Co_3O_4$ layer on the surface of $CoP_2$ that enhances acid-corrosion resistance

86  and optimizes the adsorption free energies of water and oxygen-containing species,

87  which is responsible for OER activity and stability. Accordingly, it presents low

88  overpotentials of 50 and 91 mV at 10 mA $cm^{-2}$ for HER and OER in acidic media, as

89  well as remarkable stability. Furthermore, the assembled overall water splitting cell

90  by employing V-$CoP_2$/CC as both electrodes shows a superior acidic overall water

91  splitting activity (1.47 V@10 mA $cm^{-2}$) than Pt-C/CC‖$RuO_2$/CC, and remarkable

92  stability. Additionally, it can be powered by a solar cell to continuously produce the

93  hydrogen and oxygen gases, implying its great potential for coupling with renewable

94  energy sources.

95  **Results and discussion**

96  **Catalyst synthesis and characterization.** As depicted in Fig. 1a, V-$CoP_2$/CC sample

97  was prepared through hydrothermal synthesis of V-incorporated CoOOH on the

98  carbon cloth (V-CoOOH/CC) and followed by phosphatizing treatment. Briefly,

99  V-CoOOH nanowire arrays were evenly grown on the surface of carbon cloth by

100  hydrothermal method at 120 °C for 4h (Supplementary Fig. 1, Fig. 2). Afterwards, the

101  as-prepared V-CoOOH nanowires were phosphatized at 600 °C for 2h, generating

102  V-$CoP_2$ porous nanowires with the V incorporation ratio of 5%. For comparison,

103  pure-phase $CoP_2$ grown on the carbon cloth (labeled as $CoP_2$/CC) was prepared

104  through a similar route without adding V source. Scanning electron microscopy (SEM)

105  and transition electron microscopy (TEM) images of $CoP_2$/CC show $CoP_2$ nanowires

106  with the width of ~100 nm arranged on CC are smooth and solid (Fig. 1b-c and

107  Supplementary Fig. 3). After introducing V, the nanowires arranged on CC remain

108  intact, but become coarse with many pores appeared (Fig. 1d-e). Pore information is

109  further verified by $N_2$ adsorption-desorption measurement (Fig. 1f). V-$CoP_2$/CC

110  delivers higher specific surface area (22.8 $m^2$ $g^{-1}$) with average pore diameter of ~14
**Fig. 1 Material synthesis and morphological characterization.** (a) Schematic diagram of the synthesis of V-CoP$_2$/CC. (b, c) SEM and TEM images of CoP$_2$/CC. (d, e) SEM and TEM images of V-CoP$_2$/CC. (f) N$_2$ adsorption-desorption isotherms (Inset: pore size distribution). (g, h) HRTEM images of CoP$_2$/CC and V-CoP$_2$/CC. (i) STEM image and the corresponding EDX elemental mappings of (j) Co, (k) P and (l) V of V-CoP$_2$.

nm relative to nonporous CoP$_2$/CC (5.4 m$^2$ g$^{-1}$), which is in consistent with TEM observations. Such porous nanowire structure can undoubtedly increase active surface area, promote rapid transport of electrons/reactants, and accelerate the release of gas, thus greatly boosting the electrocatalytic performance. Additionally, the influence of V incorporation ratio, and other synthetic conditions (hydrothermal and phosphorization parameters) on the morphology and structure of V-CoP$_2$/CC was also

123 studied (Supplementary Table 1 and Fig. 4-Fig. 7). As shown, appropriate synthetic

124 condition is important to produce V-CoP$_2$/CC with well-confined porous nanowire

125 structure. High-resolution TEM (HRTEM) image of CoP$_2$/CC exhibits clear lattice

126 fringes with interplanar distances of 0.243 and 0.255 nm, which can be indexed to the

127 (120) and (002) planes of CoP$_2$ (Fig. 1g). In contrast, for V-CoP$_2$, the interplanar

128 distances of (120) and (002) facets increase, proving that V incorporation causes

129 lattice expansion (Fig. 1h). STEM image and the corresponding EDX element

130 mappings manifest the uniform distribution of Co, P and V elements in V-CoP$_2$ (Fig.

131 1i-l), further illustrating the successful incorporation of V into CoP$_2$.

132   The change of CoP$_2$ by V incorporation is further investigated by a series of

133 characterizations. The crystal models of CoP$_2$ and V-CoP$_2$ are firstly established to

134 determine the influence of V incorporation on the electronic structure of CoP$_2$. Fig. 2a

135 displays the crystal structure of CoP$_2$ and V-CoP$_2$. As depicted, the lattice constants

136 increase obviously after V incorporation, which indicates the emergence of lattice

137 expansion, in good agreement with HRTEM observations. X-ray diffraction (XRD)

138 pattern of CoP$_2$/CC exhibits a diffraction peak at 26.5$^\circ$ assigned to the (002) facet of

139 graphite from carbon cloth, and other diffraction peaks indexed to CoP$_2$ (PDF No.

140 77-0263) (Fig. 2b). The XRD pattern of V-CoP$_2$ displays quite similar to that of CoP$_2$,

141 but the diffraction peaks slightly move to the lower angle region, illustrating that V

142 incorporation causes a certain expansion of interplanar distance without changing the

143 intrinsic structure of CoP$_2$[35,36]. Raman spectra of V-CoP$_2$ and CoP$_2$ in Fig. 2c reveals

144 that the incorporation of V into CoP$_2$ results in a slight blue-shift of the characteristic

145 peaks, further confirming lattice expansion of CoP$_2$ due to V incorporation[37]. To

146 further verify the existence of V and investigate the effect of V on electron structure

147 of CoP$_2$, X-ray photoelectron spectroscopy (XPS) spectra of CoP$_2$ and V-CoP$_2$ were

148 carried out. Survey spectra (Supplementary Fig. 8) show the presence of Co, P and O

149 elements both in CoP$_2$/CC and V-CoP$_2$/CC, apart from the emergence of V element in

150 V-CoP$_2$/CC. The O comes from the superficial oxidation of phosphides exposed in

151 air[38]. As shown in Fig. 2d, Co XPS spectrum of V-CoP$_2$/CC presents three doublet

152 peaks corresponding to Co-P bond (782.1/798.5 eV), Co-O bond (784.2/802.9 eV)
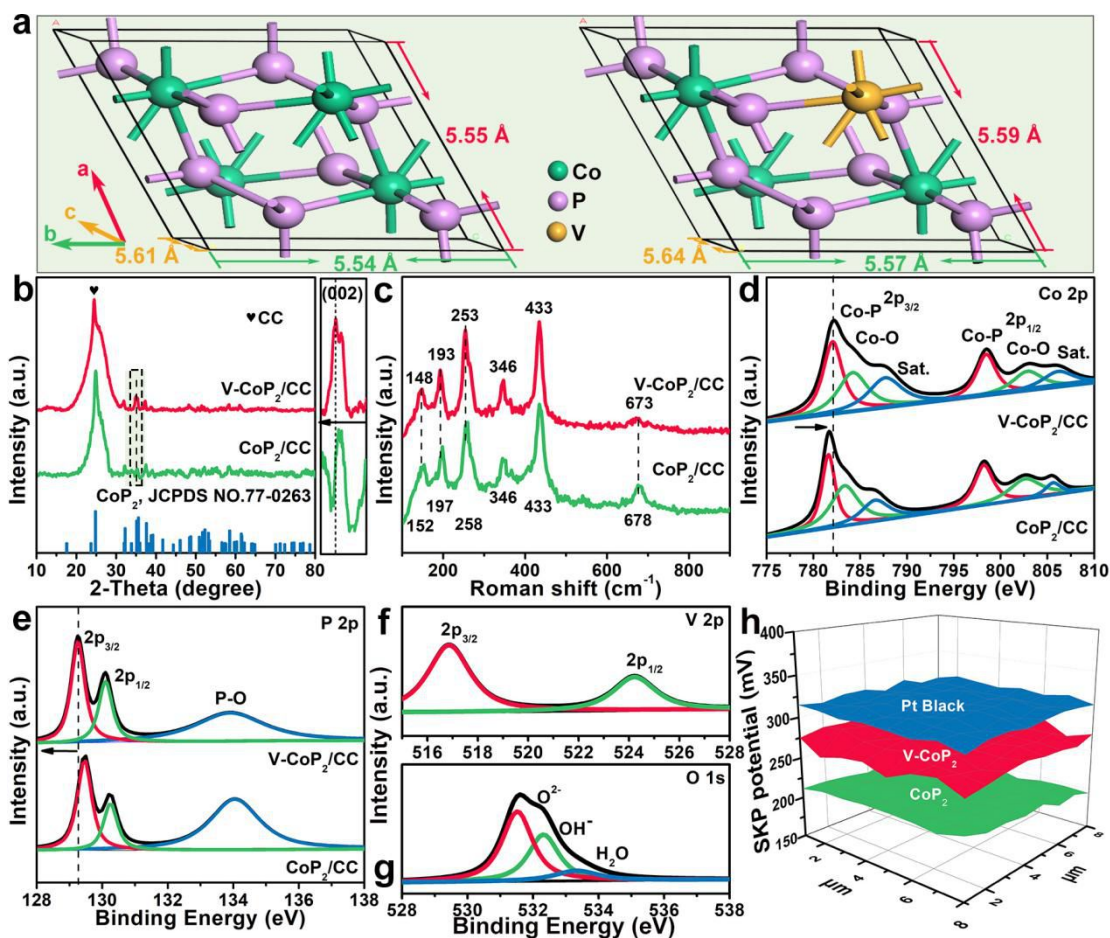

**Fig. 2 Structural characterization.** (a) Crystal models of $CoP_2$ and $V-CoP_2$ with lattice constants. (b) XRD pattern and (c) Raman spectra of $CoP_2$/CC and $V-CoP_2$/CC. XPS spectra of (d) Co 2p and (e) P 2p for $CoP_2$/CC and $V-CoP_2$/CC. XPS spectra of (f) V 2p and (g) O 1s for $V-CoP_2$/CC. (h) WF drawings of $CoP_2$, $V-CoP_2$ and Pt black.

from the superficial oxidation, and satellite signals (787.7/806.2 eV) of Co $2p_{3/2}$ and Co $2p_{1/2}$, respectively[39]. As for P 2p XPS spectrum (Fig. 2e), two peaks located at 129.5 and 130.3 eV are assigned to the Co-P bond of P $2p_{3/2}$ and P $2p_{1/2}$[40]. The peak located at 134.1 eV is attributed to P-O bond from superficial oxidation[40]. The V 2p spectrum of $V-CoP_2$/CC is detected (Fig. 2f), with two predominant peaks located at 516.9 and 524.2 eV corresponding to V $2p_{3/2}$ and V $2p_{1/2}$, which is the characteristic of $V^{4+}$[41]. The ionic radius of V in the valence of 4 is 0.58 Å, slightly large than that of Co (0.55 Å)[42]. In this case, $V^{4+}$ ion can easily insert into the lattice of $CoP_2$, thus causing lattice expansion. The O 2p region can be deconvoluted three peaks, being indexed to oxygen from metal-O, hydroxides and adsorbed $H_2O$ (Fig. 2g)[43]. Above results further confirm the successful incorporation of V in $CoP_2$. Notably, the peak positions of Co element in $V-CoP_2$ shift towards higher binding energy (0.5 eV) in

170  comparison with that of $CoP_2$, illustrating that the chemical environment of Co ion is

171  modified by incorporating V species. Meanwhile, the binding energy of P reduces 0.4

172  eV after V incorporation, indicating the increased electron density around P sites in

173  V-$CoP_2$[44]. These results manifest the electron structure modulation effect by

174  incorporating V, which is significant in regulating catalytic activity[45,46]. Additionally,

175  the work function (WF) values, calculated by performing the scanning Kelvin probe

176  (SKP) measurement, for $CoP_2$, V-$CoP_2$ and Pt black are 5.55, 5.61 and 5.65 eV,

177  respectively (Fig. 2h). Compared to $CoP_2$, the WF of V-$CoP_2$ is higher and much

178  closer to that of Pt, signifying V incorporation induces electronic characteristic more

179  similar to Pt, which is undoubtedly favorable for electrocatalysis.

180  **Electrocatalytic hydrogen evolution.** The HER performance of the as-prepared

181  V-$CoP_2$/CC electrode was evaluated in acidic solution using a typical three-electrode

182  system. Bare CC, $CoP_2$/CC, and Pt-C coated on CC (Pt-C/CC) were tested for

183  comparison. The iR-compensated linear sweep voltammetry (LSV) curves show that

184  V-$CoP_2$/CC presents the excellent catalytic activity. Specifically, V-$CoP_2$/CC requires

185  an onsetpotential ($\eta_{onset}$) of zero, which is comparable to that of Pt-C/CC (Fig. 3a).

186  V-$CoP_2$/CC also shows overpotential advantage at large current densities. The

187  overpotentials to achieve the current densities of 10, 50 and 100 mA $cm^{-2}$ are 50 ($\eta_{10}$),

188  134 ($\eta_{50}$) and 181 mV ($\eta_{100}$) for V-$CoP_2$/CC, which much lower than those of

189  $CoP_2$/CC (123, 257 and 355 mV), and approach those of Pt-C/CC (32, 71 and 107 mV)

190  (Fig. 3b and Supplementary Table 2). Furthermore, the superiority of V-$CoP_2$/CC

191  over the other reported Co-based and V-based electrocatalysts in acidic media is also

192  confirmed (Supplementary Table 3).

193      To inspect the HER kinetics, Tafel plots were calculated by the LSV curves as

194  depicted in Fig. 3c. The measured Tafel slope for V-$CoP_2$/CC is 32 mV $dec^{-1}$, which

195  is much smaller than that of $CoP_2$/CC (89 mV $dec^{-1}$) and much close to that of

196  Pt-C/CC (31 mV $dec^{-1}$), suggesting the Volmer-Tafel mechanism for V-$CoP_2$/CC. The

197  electrochemical impedance spectroscopy (EIS) was performed to study the reaction

198  kinetics. Apparently, V-$CoP_2$/CC delivers a smaller charge transfer resistance ($R_{ct}$) of

199  ~2 Ω than $CoP_2$/CC (~7 Ω) (Fig. 3d), which implies the enhanced charge transfer
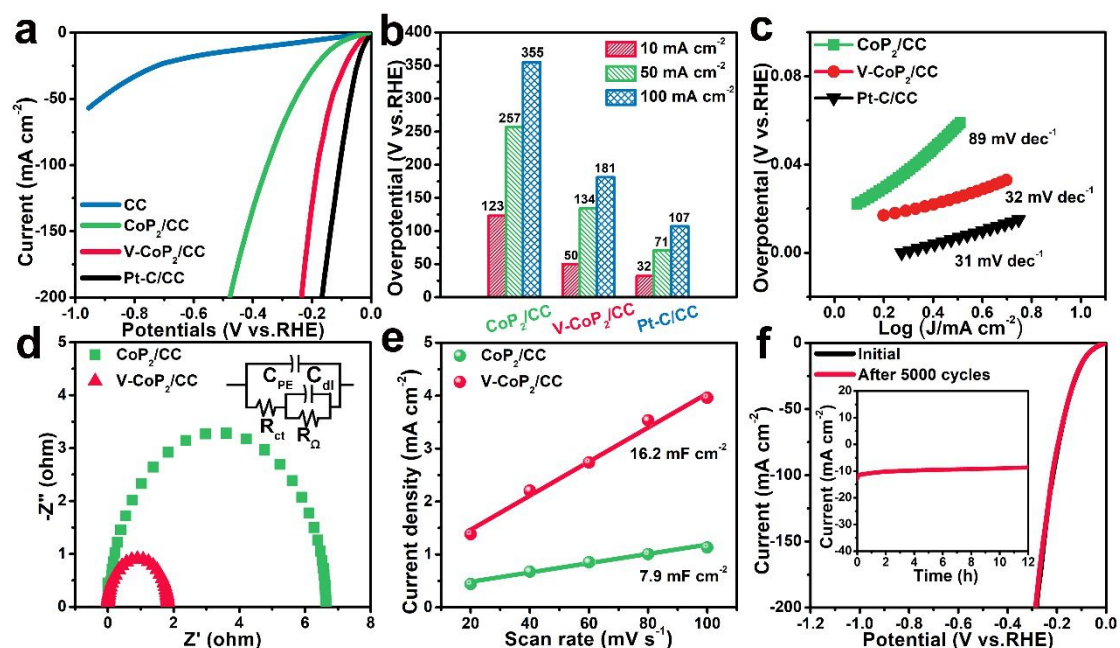

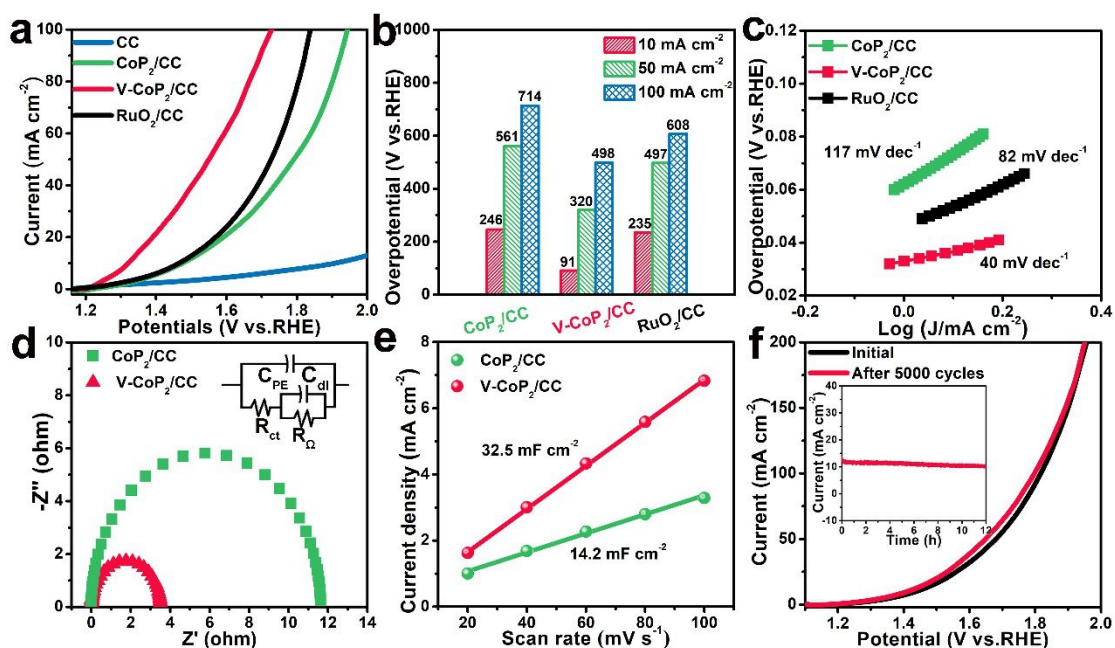

**Fig. 3 Electrochemical HER performance**. (a) LSV curves of CC, CoP₂/CC, V-CoP₂/CC and Pt-C/CC in 0.5 M H₂SO₄. (b) Comparison of overpotentials at 10, 50 and 100 mA cm⁻² and (c) Tafel plots for CoP₂/CC, V-CoP₂/CC and Pt-C/CC. (d) Nyquist plots and (e) capacitive currents at 0.1 V as a function of the scan rate for CoP₂/CC and V-CoP₂/CC. (f) LSV curves of V-CoP₂/CC before and after 5000 cycles. Insert: I-t chronoamperometric curve for V-CoP₂/CC during HER process for 12h.

kinetics contributed by vanadium incorporation. Additionally, the dependencies of the HER activity on the incorporation concentration, as well as hydrothermal and phosphorization conditions were also investigated. Clearly, V-CoP₂/CC obtained by V incorporation ratio of 5%, along with hydrothermal time of 2h and phosphrization at 600 °C for 2h exhibits the maximum HER activity (Supplementary Fig. 9-Fig. 12). Electrochemical active surface area (ECSA) was calculated through the double layer capacitance ($C_{dl}$) from the cyclic voltammetry (CV) method (Supplementary Fig. 13). V-CoP₂/CC possesses a larger $C_{dl}$ of 16.2 mF cm⁻² than CoP₂/CC (7.9 mF cm⁻²). The high $C_{dl}$ of V-CoP₂/CC stands that appropriate vanadium incorporation brings in more active sites, benefiting to good HER performance (Fig. 3e). Furthermore, LSV curves normalized by ESCA were employed to estimate the specific catalytic activity. As depicted in Supplementary Fig. 14, V-CoP₂/CC still shows better HER performance. To further investigate the intrinsic catalytic activity, turnover frequency (TOF) and exchange current density ($j_0$) are evaluated. V-CoP₂/CC shows higher TOF value of 0.379 s⁻¹ at 100 mV than

222      $CoP_2/CC$ (0.137 $s^{-1}$) (Supplementary Fig. 15). Meanwhile, the $j_0$ of $V-CoP_2/CC$

223      (0.318 mA $cm^{-2}$) is consistently larger that of $CoP_2/CC$ (0.207 mA $cm^{-2}$)

224      (Supplementary Fig. 16). The large specific activity, TOF and $j_0$ values of

225      $V-CoP_2/CC$ demonstrate that vanadium incorporation induces the essential change on

226      catalytic surface of $CoP_2$. Last, the stability of $V-CoP_2/CC$ was assessed by CV cycles

227      and I-t chronoamperometric tests. The polarization curve of $V-CoP_2/CC$ presents a

228      negligible catalytic degradation after 5000 CV cycles (Fig. 3f). The I-t

229      chronoamperometric test of $V-CoP_2/CC$ exhibits an ignorable loss of current density

230      even after 12h (inset of Fig. 3f). Both of the tests validate its superb stability. The

231      structural information of $V-CoP_2/CC$ after HER electrocatalysis was further

232      investigated. $V-CoP_2/CC$ still maintains the nanowire morphology and show a

233      negligible structure and composition change (Supplementary Fig. 17, Fig. 18),

234      suggesting that there is no obvious surface reconstruction during HER electrolysis and

235      the boosted HER activity mainly comes from the V incorporation.

236      **Electrocatalytic oxygen evolution.** The anodic OER performance was also evaluated.

237      As shown in Fig. 4a, $V-CoP_2/CC$ performs a low $\eta_{onset}$ of 70 mV, which is better than

238      $RuO_2/CC$ (185 mV). Moreover, $V-CoP_2/CC$ presents the lowest overpotentials of 91,

239      320 and 498 mV at 10, 50 and 100 mA $cm^{-2}$, as compared with $CoP_2/CC$ (246, 561

240      and 714 mV) and $RuO_2/CC$ (235, 497 and 608 mV) (Fig. 4b and Supplementary Table

241      2). It also outperforms the recently reported noble-metal-based OER catalysts in

242      acidic solution (Supplementary Table 4). In addition, $V-CoP_2/CC$ exhibits a lowest

243      Tafel slope of 40 mV $dec^{-1}$ relative to $CoP_2/CC$ (117 mV $dec^{-1}$) and $RuO_2/CC$ (82 mV

244      $dec^{-1}$) (Fig. 4c), illustrating the optimum OER kinetics. $V-CoP_2/CC$ delivers a smaller

245      $R_{ct}$ of ~4 $\Omega$ than $CoP_2/CC$ (~12 $\Omega$), further suggesting the promoted OER kinetics by

246      vanadium incorporation (Fig. 4d). Coincident with HER performance, $V-CoP_2/CC$

247      with V incorporation ratio of 5%, prepared by hydrothermal time of 2h and

248      phosphorization at 600 $^oC$ for 2h shows the best OER activity (Supplementary Fig.

249      19-Fig. 22). Besides, as determined by CV curves (Supplementary Fig. 23),

250      $V-CoP_2/CC$ possesses a larger $C_{dl}$ of 32.5 mF $cm^{-2}$ than $CoP_2$ (14.2 mF $cm^{-2}$),

251      indicating more active sites caused by V incorporation (Fig. 4e). Accordingly,

**Fig. 4 Electrochemical OER performance.** (a) LSV curves of CC, CoP$_2$/CC, V-CoP$_2$/CC and RuO$_2$/CC in 0.5 M H$_2$SO$_4$. (b) Comparison of overpotentials at 10, 50 and 100 mA cm$^{-2}$ and (c) Tafel plots for CoP$_2$/CC, V-CoP$_2$/CC and RuO$_2$/CC. (d) Nyquist plots and (e) capacitive currents at 1.15 V as a function of the scan rate for CoP$_2$/CC and V-CoP$_2$/CC. (f) LSV curves of V-CoP$_2$/CC before and after 5000 cycles. Insert: i-t chronoamperometric curve for V-CoP$_2$/CC during OER process for 12h.

the ESCA-normalized specific activity of V-CoP$_2$/CC surpasses that of CoP$_2$/CC (Supplementary Fig. 24). V-CoP$_2$/CC also exhibits a higher TOF value of 0.207 s$^{-1}$ at overpotential of 240 mV than CoP$_2$/CC (0.096 s$^{-1}$) (Supplementary Fig. S25). These results manifest the synchronously increased active sites and intrinsic activity by V incorporation. The V-CoP$_2$/CC catalyst shows no obvious loss of current density no mater after CV cycles or I-t chronoamperometric test, suggesting its excellent OER stability. While CoP$_2$/CC exhibits complete loss of current density within 6h (Supplementary Fig. 26). These observations stand for the important role of V on improving OER stability of CoP$_2$/CC in acidic solution.

To probe the activity and stability origin of V-CoP$_2$/CC for OER in acidic media, a series of post OER characterizations were performed. The CoP$_2$/CC catalyst after OER electrocatalysis was also evaluated for comparison. TEM image (Fig. 5a) of CoP$_2$/CC after OER electrocatalysis shows a very thin Co-oxide layer with the average thickness of ~5 nm around the surface of CoP$_2$. Such a thin Co-oxide layer could not effectively resist the strong oxidation in acidic media, resulting in the worse
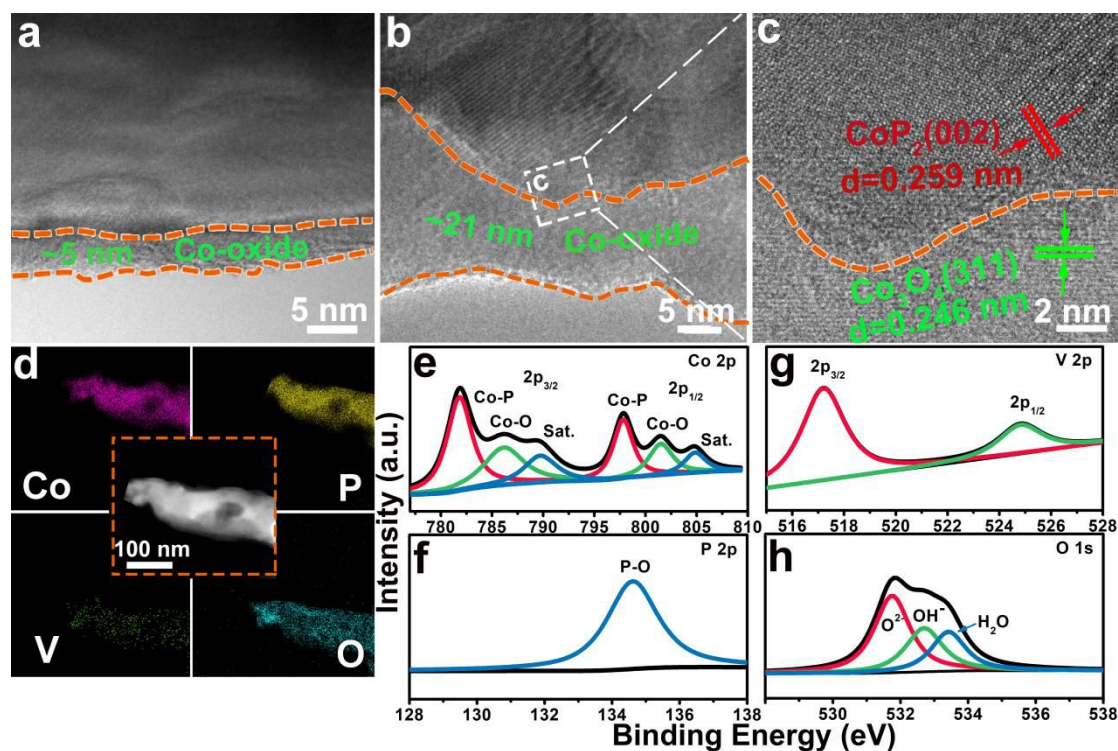

**Fig. 5 Morphology and properties of the post OER.** TEM images of (a) $CoP_2$/CC and (b) V-$CoP_2$/CC. (c) HRTEM image of V-$CoP_2$/CC. (d) STEM image and the corresponding EDX elemental mapping of Co, P, V and O of V-$CoP_2$. XPS spectra of (e) Co 2p, (f) P 2p, (g) V 2p and (h) O 1s in V-$CoP_2$.

stability of $CoP_2$/CC. By contrast, a thicker Co-oxide layer with the average thickness of ~21 nm is observed in the V-$CoP_2$/CC (Fig. 5b). The above results indicate that V incorporation promotes the surface reconstruction of $CoP_2$. HRTEM image of V-$CoP_2$ /CC after OER electrocatalysis further corroborates the existence of inner $CoP_2$ and outer $Co_3O_4$ phases with well crystallization (Fig. 5c). The well-crystallized $Co_3O_4$ layer, which acts as an "armor", can enhance corrosion resistance in acidic OER process. Besides, STEM image and EDX elemental mappings prove the homogeneous distribution of O element in the V-$CoP_2$/CC after OER, in addition to Co, P and V elements (Fig. 5d), confirming the formation of $Co_3O_4$ layer on the $CoP_2$ surface. The dramatic surface chemical change during OER is further reflected by XPS spectra. As shown in Co XPS spectrum, the relative intensities of peaks attributed to Co oxides increase obviously after OER (Fig. 5e). Meanwhile, with respect to P XPS spectrum, the peaks related to Co-P bonds disappear, accompanied by the strengthened peak intensity assigned to P-O bond (Fig. 5f). These results validate the fact of entirely surface oxidation of $CoP_2$ after OER. In the case of V, the binding energies of V $2p_{3/2}$

294 and V $2p_{1/2}$ peaks related to $V^{4+}$ show positive shift (517.2 and 524.5 eV) (Fig. 5g),

295 indicating the valence of V ionic becomes higher after OER. Besides, O XPS

296 spectrum displays an obvious increased intensity of peak belonging to the adsorbed

297 $H_2O$ (Fig. 5h), suggesting the $H_2O$ adsorption ability is improved by V incorporation.

298 Thus, we deduce the reason that V promotes the surface reconstruction of $CoP_2$ as

299 follows. $V^{4+}$ ion is extremely oxyphilic or hydrophilic because of its highly

300 positive-charged and unfilled d-orbital[47], so that it facilitates the adsorption and

301 dissociation of $H_2O$ to produce more hydroxyl groups. Then, the hydroxyl groups

302 preferentially attach to the unoccupied Co site on the surface (lesser energy barrier)[48],

303 thus leading to the formation of a thicker $Co_3O_4$ layer. In short, $V^{4+}$ promotes the

304 surface reconstruction of $CoP_2$ and the *in-situ* generated thicker $Co_3O_4$ layer can resist

305 corrosion in acidic OER process. What's more, the inner phosphide provides a good

306 conductive platform. The above two points render V-$CoP_2$/CC outstanding activity

307 and stability towards OER.

308 **Study on catalytic mechanism.** Density functional theory (DFT) calculations were

309 performed to elucidate the origin of the enhanced HER and OER activities. The

310 correlative theoretical models were established (Supplementary Fig. 27). Fig. 6a

311 shows the orbital wave function mappings of $CoP_2$ and V-$CoP_2$. The introduction of V

312 into $CoP_2$ decreases atomic orbital wave function overlap integrals. The change of

313 orbital wave function shrinks energy difference between the highest and lowest orbital

314 levels in the local band and further narrows the local energy bandwidth[49]. As the

315 bandwidth narrows, the d-band center ($E_d$) of $CoP_2$ will shift to keep the number of

316 fixed valence electrons. This can be corroborated by the density of states (DOS). For

317 HER, after V incorporation, the $E_d$ of $CoP_2$ without and with H adsorption relative to

318 Fermi level shift from -1.33 to-1.29 eV and -3.56 to-3.50 eV, respectively (Fig. 6b).

319 The result clearly demonstrates the upshift of d-band center after V incorporation.

320 Besides, the antibonding level is raised and the interaction between the adsorbate and

321 surface is enhanced based on d-band center model[33]. Above results give the intrinsic

322 explication that the upshift of d-band center and the less electrons filled in

323 antibonding states after incorporating V increases the adsorption of hydrogen.
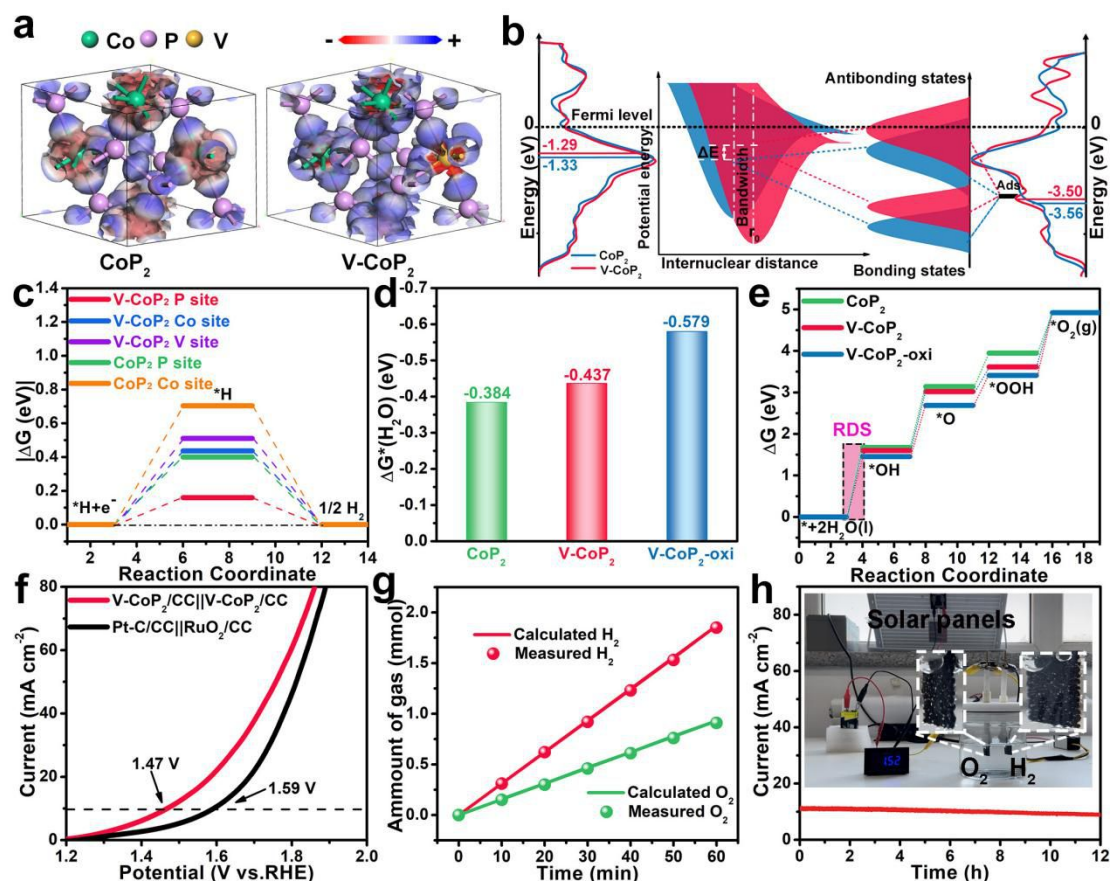

**Fig. 6 DFT calculations and overall water splitting performance.** (a) Orbital wave function mappings of $CoP_2$ and $V\text{-}CoP_2$. (b) DOS of $CoP_2$ and $V\text{-}CoP_2$ with/without hydrogen adsorption and the schematic diagram of the relation between the narrowed bandwidth and H adsorption strength. (c) Free energy diagram of $CoP_2$ and $V\text{-}CoP_2$ with various sites for HER. (d) Calculated $H_2O$ adsorption energy and (e) free energy diagram of $CoP_2$, $V\text{-}CoP_2$ and $V\text{-}CoP_2\text{-}oxi$ for OER. (f) LSV curves of two-electrode OWS devices with $V\text{-}CoP_2/CC\|V\text{-}CoP_2/CC$ and $Pt\text{-}C/CC\|RuO_2/CC$ catalysts. (g) Amount of gas collected and calculated for $V\text{-}CoP_2/CC\|V\text{-}CoP_2/CC$. (h) I-t chronoamperometric curve performed at a constant voltage of 1.47 V for 12h. Insert: Demonstration of a water splitting device driven by a solar cell with a voltage of 1.52 V.

Besides, the effects of V on the free energy of hydrogen ($\Delta G_{H*}$) were investigated. A catalyst with $\Delta G_{H*}$ closer to zero is regarded as an ideal candidate for HER. $V\text{-}CoP_2$ holds a much smaller $|\Delta G_{H*}|$ than $CoP_2$ (Fig. 6c and Supplementary Fig. 28, Table 5), indicating that $V\text{-}CoP_2$ is highly active for HER. Moreover, the smallest $|\Delta G_{H*}|$ at P site in $V\text{-}CoP_2$ indicates that P site is the active site for HER. This can be ascribed to the high electron density at P site induced by V incorporation, as verified by XPS analysis, which is conducive to adsorbing more hydrogen protons.

With respect to OER in acidic media, the water adsorption and the adsorption/desorption of various intermediates (OH*, O* and OOH*) are the key

343  descriptors. The water adsorbed energy ($E_{H2O}$) on $CoP_2$, $V\text{-}CoP_2$ and O-substituted

344  $V\text{-}CoP_2$ ($V\text{-}CoP_2\text{-}oxi$) were calculated, respectively (Supplementary Fig. 29-Fig. 31).

345  The larger $E_{H2O}$ of $V\text{-}CoP_2$ (-0.437 eV) than that of $CoP_2$ (-0.384 eV) indicates that V

346  incorporation increases the effective water adsorption (Fig. 6d and Supplementary

347  Table 5), which is in good agreement with XPS observation after OER. Notably, the

348  $E_{H2O}$ further increases to -0.579 eV for $V\text{-}CoP_2\text{-}oxi$, illustrating that $H_2O$ can be more

349  easily adsorbed and activated on $V\text{-}CoP_2\text{-}oxi$ to promote the OER process[50]. In

350  addition, Fig. 6e shows the free energies of various intermediates adsorbed on $CoP_2$,

351  $V\text{-}CoP_2$ and $V\text{-}CoP_2\text{-}oxi$. The adsorbed energy difference between $\Delta G_{H2O}$ and $\Delta G_{OH*}$

352  determines the rate-determining step (RDS), which is a vital criterion for evaluating

353  the catalytic activity. $V\text{-}CoP_2\text{-}oxi$ owns the smallest RDS energy difference (1.46 eV),

354  as compared with $CoP_2$ (1.68 eV) and $V\text{-}CoP_2$ (1.60 eV), indicating the significant

355  role of oxide species in the catalyst on accelerating OER. Together, above results

356  suggest that V incorporation promotes surface reconstruction to generate a thicker

357  layer of oxides, which favors the OER kinetics and optimizes the adsorption energies

358  of water and oxygen species, thereby improving OER activity and stability.

359  **Overall water splitting performance.** In light of the outstanding bifunctional

360  catalytic feature of $V\text{-}CoP_2/CC$ for acidic HER and OER, two identical $V\text{-}CoP_2/CC$

361  electrodes were employed to assemble two-electrode overall water splitting (OWS)

362  device. $V\text{-}CoP_2/CC \| V\text{-}CoP_2/CC$ merely requires a low voltage of 1.47 V to achieve

363  the current density of 10 mA $cm^{-2}$, which outperforms the $Pt\text{-}C/CC \| RuO_2/CC$-based

364  electrolyzer (1.59 V@10 mA $cm^{-2}$) (Fig. 6f). Remarkably, the overall water splitting

365  performance is also superior to most of the reported noble metal-based

366  electrocatalysts in acidic media (Supplementary Table 6). Additionally,

367  $V\text{-}CoP_2/CC \| V\text{-}CoP_2/CC$ shows high Faradaic efficiencies close to 100% for both

368  HER and OER (Fig. 6g), demonstrating the high reaction efficiency and negligible

369  side reactions. $V\text{-}CoP_2/CC // V\text{-}CoP_2/CC$ also exhibits superb stability with no obvious

370  decrease in activity after continuous operation at 1.47 V for 12h (Fig. 6h).

371  Impressively, the electrolyzer can be driven by a solar cell with a low voltage of 1.52

372  V, in which many gas bubbles can be observed, indicating its potential for coupling

373  with renewable energy sources (inset of Fig. 6h and Supplementary Movie 1).

374      In summary, we have designed V-incorporated $CoP_2$ porous nanowires anchored

375  on carbon cloth (V-$CoP_2$/CC) as a bifunctional electrocatalyst for overall water

376  splitting in acidic media. The lattice expansion of $CoP_2$ caused by V incorporation

377  decreases the atomic wave function overlap and renders the upshift of d-band center,

378  as verified by a series of structural characterizations and theoretical analysis. The

379  upshift of d-band center in V-$CoP_2$ induces more hydrogen adsorption on P sites,

380  which gives rise to an enhanced HER activity. In addition, a thicker $Co_3O_4$ layer on

381  the $CoP_2$ surface that is generated from surface reconstruction promoted by V

382  incorporation, improves acid-corrosion resistance and optimizes the adsorption free

383  energies of water and oxygen species, accounting for the catalytic OER performance.

384  The catalyst exerts superb catalytic performances for both HER and OER.

385  Impressively, the electrolyzer requires a low voltage of 1.47 V at 10 mA cm$^{-2}$, and can

386  be easily driven by a solar cell. This work offers a new approach to design efficient

387  electrocatalysts through lattice engineering induced by heteroatom incorporation.

388  **Methods**

389  **Chemicals.** Cobalt nitrate hexahydrate ($Co(NO_3)_2 \cdot 6H_2O$), ammonium metavanadate ($NH_4VO_3$),

390  ammonium fluoride ($NH_4F$, analytical reagent 98%) and urea ($CO(NH_2)_2$) were purchased from

391  Aladdin Reagent Co., Ltd. Sodium hypophosphite ($NaH_2PO_2$, analytical reagent 99.5%) was

392  purchased from Kermel. Ethanol was obtained from Tianjin Kermel Chemical Reagent Co., Ltd.

393  All chemicals were used as received without any further purification.

394  **Synthesis of V-$CoP_2$ porous nanowire.** In a typical synthesis, 0.05 mmol of $NH_4VO_3$, 0.95 mmol

395  of $Co(NO_3)_2 \cdot 6H_2O$, 5 mmol of $CO(NH_2)_2$, and 2 mmol of $NH_4F$ were dissolved in 25 mL of

396  deionized water and stirred for 2h to form a homogeneous solution. Afterward, the mixture was

397  transferred to a 50-mL Teflon-lined stainless steel autoclave containing CC (3 × 3 cm$^{-2}$) and

398  hydrothermally treated at 120 $^o$C for 4h. After cooling to the room temperature, the V-CoOOH

399  precursors grown on the CC (V-CoOOH/CC) were ultrasonically cleaned with deionized water

400  and ethanol for several times and dried in an oven at 60 $^o$C overnight. Finally, 1.2 g of $NaH_2PO_2$

401  powder and V-CoOOH/CC were placed on the upstream and downstream of the quartz tube,

402  respectively. Before phosphorization, $N_2$ was purged for 20 min to remove the air. The

403  V-CoOOH/CC was heated at 600 $^oC$ with a ramp rate of 2 $^oC$ min$^{-1}$ and maintained at 600 $^oC$ for

404  2h. After cooling to room temperature, the V-CoP$_2$/CC was harvested, in which the V

405  incorporation ratio is 5%. For comparison, CoP$_2$/CC were prepared with similar process to that

406  employed for the fabrication of V-CoP$_2$/CC, except that only adding Co source. Additionally, a

407  series of control experiments were performed. Specifically, the corresponding phosphorization

408  products with other hydrothermal times of 2 and 6h were prepared (labeled as V-CoP$_2$/CC-2 and

409  V-CoP$_2$/CC-6). The V-CoP$_2$/CC samples with other V incorporation ratios of 2.5% and 10% were

410  prepared (named as V-CoP$_2$/CC-2.5% and V-CoP$_2$/CC-10%). The V-CoOOH/CC was treated at

411  the phosphorization temperatures of 500 and 700 °C and labeled as V-CoP$_2$/CC-T500 and

412  V-CoP$_2$/CC-T700. The V-CoOOH/CC was phosphatized for 1 and 3h and tagged as

413  V-CoP$_2$/CC-T1h and V-CoP$_2$/CC-T3h.

414  **Material Characterizations.** The crystal phase of the samples were determined by Bruker D8

415  diffractometer X-ray powder diffraction (XRD) with Cu Kα radiation and the acceleration voltage

416  of 40 kV). Scanning electron microscopy (SEM: Hitachi s-4800) and transmission electron

417  microscopy (TEM: JEM-2100) with an acceleration voltage of 200 kV and energy dispersive

418  X-ray spectroscopy (EDX) were used to analyze the morphology of samples. Raman was

419  conducted with a Jobin Yvon HR 800 micro-Raman spectrometer at 457.9 nm. X-ray

420  photoelectron spectroscopy (XPS) characterization was conducted on a VG ESCALAB MK II

421  with the excitation source of Mg Kα (1253.6 eV) achromatic X-ray radiation. The $N_2$

422  adsorption-desorption isotherms of the samples were performed by Micromeritics Tristar II.

423  Scanning Kelvin Probe ((SKP5050 system, Scotland) were performed in ambient atmosphere with

424  a gold electrode as the reference electrode. The amount of gases was quantified by gas

425  chromatography (Aglient, 7820A).

426  **Electrochemical measurements.** Electrochemical measurements were performed with a

427  CHI660E electrochemical workstation. A three-electrode configuration at room temperature was

428  used, where self-supported electrocatalytic materials, graphite rod and saturated calomel electrode

429  (SCE) were used as the work electrode, the auxiliary electrode and the reference electrode,

430  respectively. All the potentials were recorded with respect to the reversible hydrogen electrode

431  (RHE) and 95% iR-corrected according to the equation $E_{RHE} = E_{SCE} + 0.244$ V$+0.059$pH-iR.

432    Linear sweep voltammetry was collected in 0.5 M $H_2SO_4$ with the scan rate of 5 mV $s^{-1}$. The

433    potential cycling stability test was examined by taking continuous cyclic voltemmgrams (CVs) at

434    a scan rate of 100 mV $s^{-1}$. The I-t chronoamperometric test was tested for 12h at the potential

435    required 10 mA $cm^{-2}$. Electrochemical impedance spectroscopy (EIS) was performed with

436    frequency range from 1 Hz to 100 kHz. CV curves were conducted with different rates from 20 to

437    100 mV $s^{-1}$ to determine double-layer capacitance. The voltage range for overall water splitting

438    was tested from 1 to 2 V. The Faradaic efficiencies for HER and OER were measured by

439    comparing the experimental and theoretical amounts of $H_2$ and $O_2$. In the test, potentiostatic

440    electrolysis was employed at 100 mA $cm^{-2}$ for 1h.

441    **Computational details.** The projector augmented-wave (PAW) technique with the set plane-wave

442    energy cutoff of 300 eV was conducted[51]. Perdew-Burke-Ernzerhof (PBE) functional was

443    employed to settle the correlation-exchange energies of the systems[52]. The sampling over

444    Brillouin zone was treated by a (2×2×1) Monkhorst-Pack grid, and a vacuum slab with the length

445    of 10 Å was placed along z axis on each slab to avoid the pseudo interactions between periodic

446    images. Geometry optimization was repeated until the total energy tolerance was converged to

447    $2*10^{-5}$ eV and the changes of the force on the atoms less than 0.03 eV/Å.
