Abstract

Background: Cataract is the leading cause of blindness globally and more people will be at risk for this common cause of vision loss in the coming years.

To estimate the disease burden of cataract and evaluate contributions of various risk factors to cataract-associated disability-adjusted life years (DALYs).

Methods: Prevalence of visual impairment due to cataract and disability-adjusted life years of cataract were extracted from the Global Burden of Disease (GBD) study 2019 to explore time trends and annual changes. Regional and country-level socioeconomic indexes were acquired from open databases, and stepwise multiple linear regression was used to evaluate associations between age-standardized rate of DALYs of cataract and potential predictors.

Results: Global Prevalence rate of visual impairment due to cataract rose by 58.45% from 791.4 per 100,000 population (95%CI: 705.2 to 890.0 per 100,000 population) to 1253.9 per 100,000 population (95%CI: 1103.3 to 1417.7 per 100,000 population) in 2019 and DALYs rate of cataract rose by 32.18% from 65.3 per 100,000 population (95%CI: 46.4 to 88.2 per 100,000 population) in 1990 to 86.3 per 100,000 population (95%CI: 61.5 to 116.4 per 100,000 population) in 2019. Stepwise multiple linear regression model showed that higher refractive error prevalence ($\beta=0.036$, 95% CI: 0.022, 0.050, $P<0.001$), lower number of physicians per 10,000 population ($\beta=-0.959$, 95% CI: -1.685, -0.233, $P=0.010$) and lower level of HDI ($\beta=-134.93$, 95% CI: -209.84, -60.02, $P=0.001$) were associated with higher disease burden of cataract.

Conclusions: Substantial increases in the prevalence of visual impairment and DALYs of cataract were observed from 1990 to 2019. Successful global initiatives targeting improving cataract surgical rate and quality, especially in regions with lower socioeconomic status, is a prerequisite to combating this growing burden of cataract in the aging society.

Background

Cataract is the leading cause of blindness globally and has been a primary focus of many national programs aimed at meeting the Vision 2020 objectives.[1] Despite being treatable with a straightforward and cost-effective surgery, one of the greatest challenges facing ophthalmology globally today remains the unacceptably high backlog of operable cataract blindness, especially in the developing world.[2, 3] It is reported that in 2015, cataract contributed to 55% of blindness among adults aged 50 years and older. [4] With the increase in the aging global population, more people will be at risk for this common cause of vision loss in the coming years.[5, 6] According to the World Health Organization (WHO) report on vision 2019, there are at least 1 billion people with preventable moderate or severe distance vision impairment or blindness, including 65.2 million caused by cataract.[5]

Although many breakthroughs have been made since the inception of Vision 2020 and decreasing blindness prevalence has been achieved during the past decades, the number of blind people continues to increase rapidly.[4, 7] The rates of cataract surgery are increasing globally and postoperative outcomes are improving, yet challenges to reducing the cataract burden remain.[3] The Global Burden of Disease (GBD) 2017 Study reported that cataract caused the second largest burden of disability-adjusted life years (DALYs) among eye diseases (8 million), next only to near vision loss.[8] Meanwhile, the DALYs attributed to cataract increased by nearly 30% from 2007 to 2017.[8] To the best of our knowledge, few studies have specifically assessed the global change in cataract burden thus far.[9, 10]

By 2030, the number of people worldwide aged 60 years and over is estimated to increase 1.4 billion. Given most people over the age of 60 years will develop cataract, the number of people with this condition will also increase substantially.[11] A successful response to managing this impending challenge requires timely, reliable, quantitative information to design effective interventions aimed at counteracting the disease burden of cataract. Based on the currently available data on the global scale from the GBD, the present study aimed to provide updated information on the global burden of cataract to better inform key stakeholders contributing to the implementation for future health policies.

Methods

Disease Burden of Cataract

The disease burden due to cataract (prevalence of visual impairment and DALYs) was obtained from the Global Disease Burden 2019 in the GHDx (<http://ghdx.healthdata.org/gbd-results-tool>), where the global burden of 369 diseases and injuries of 204 countries and territories were presented and its details of methodology were described.[12] The definition of DALYs is the sum of the years lost due to disability and the years lived with disability by the following formula: DALY number = (Number of deaths × Standard life expectancy at age of death in years) + (Number of prevalent cases × Disability weight). [12, 13] The prevalence of visual impairment due to cataract and DALYs of cataract was calculated for populations aged 20 years and above, and DALYs rate was adjusted for population size, with age standardized DALYs rate further adjusted for age structure.

Further analyses were conducted using the data below: (1) the global, GBD regions and GBD super regions numbers, rates and age-standardized rates of DALYs and prevalence of visual impairment due to cataract from 1990 to 2019; (2) country-level age-standardized DALY rate of 2019.

Patient and public involvement

Patients and the public were not involved in this study.

Country-level indicators

In order to assess the correlation between disease burden of cataract and potential associated factors, various country level indexes were included for statistical analysis. Former studies gave the conclusion that some of the common ocular diseases, such as glaucoma and refractive error, are positively

associated with the development of cataract.[14–16] Meanwhile, individuals with diabetes mellitus are at a higher risk of developing cataract. [17, 18] The prevalence of diseases mentioned above were extracted from the GBD 2019 Study.[12] Cataract surgical rate, defined as number of cataract surgeries performed annually per million population, indicates the progress in cataract control and was also included for analysis.[19–21]

In terms of included socioeconomic factors, Socio-demographic Index (SDI) is a commonly used index to assess social and economic development level of a country from GHDx, which classify countries into 5 categories as high SDI, middle-high SDI, middle SDI, low-middle SDI and low SDI. Another comparable indicator, Human Development Index (HDI), was extracted from the United Nations Development Programme's (UNDP) database (<http://hdr.undp.org/en/data>). HDI consists of 4 components across health, education and income dimensions: life expectancy at birth, expected years of schooling, mean years of schooling and gross national income per capita (GNI). The HDI ranged from 0 to 1, and countries were accordingly divided into 4 groups: very high HDI (HDI 0.800 and above), high HDI (HDI 0.700-0.799), medium HDI (HDI 0.55–0.699) and low HDI (HDI 0.549 and below). Inequality-adjusted HDI was also adapted as it adjusted for the inequal distribution of the HDI within each country. Populations with at least some secondary education (aged 25 and older) is an indicator for evaluation of education level among one country in addition to the 2 components of HDI. Number of physicians, defined by the number of medical doctors per 10,000 population, reflects the healthcare level of a country.

Statistical analysis

The results are composed of time trends of the prevalence of visual impairment due to cataract and DALYs numbers, DALYs rate, and age standardized DALYs rate attributable to cataract. The global distribution of prevalence of visual impairment due to cataract was downloaded from the GHDx (<https://vizhub.healthdata.org/gbd-compare/>). One-way analysis of variance (ANOVA) was performed to detect GBD regional as well as GBD super regional difference in age-standardized DALY rate. Scatter plot with regression curve was drawn to evaluate the correlation between age-standardized DALY rates and SDI. Univariate and stepwise linear regression analyses were used to investigate potential correlation with common ocular and endocrine diseases, demographic, socioeconomic and healthcare indicators. Variables significant at a level of $P \leq 0.2$ in univariate regression were included in multiple stepwise regression analysis. Figures were conducted using GraphPad Prism software (V.5.01, GraphPad Software; San Diego, California, USA), while statistical analyses were conducted using Stata MP 15.1 (Stata Corp LP, College Station, Texas, USA). A value of $P < 0.05$ was considered statistical significance unless otherwise specified.

Results

Time trends of disease burden attributable to cataract from 1990 to 2019

The global trend of prevalence of visual impairment due to cataract and DALYs caused by cataract are presented in Figs. 1 & 2. Prevalence cases of cataract with visual impairment showed a steady increase by 129.2%, from 4233,6679 (95%CI: 3772,8563, 4761,5115) in 1990 to 9702,2038 (95%CI: 8537,0876, 1,0969,6644) in 2019. Prevalence rate of visual impairment due to cataract also had an upward trend, rising by 58.45% from 791.4 per 100,000 population (95%CI: 705.2 to 890.0 per 100,000 population) in 1990 to 1253.9 per 100,000 population (95%CI: 1103.3 to 1417.7 per 100,000 population) in 2019. Age-standardized prevalence of visual impairment due to cataract fluctuated with its lowest in 1994 (1125.55, 95%CI: 1004.97, 1256.61 per 100,000 population) and highest in 2017 (1283.53, 1134.46, 1442.93 per 100,000 population).

In general, trends of DALYs number and DALYs rate were similar to those of the prevalence of visual impairment due to cataract, as DALY numbers increased by 91.2% from 349,2604 (95%CI: 248,1846, 471.9629) in 1990 to 667,6281 (95%CI: 476,1210, 900,6193) in 2019. When it comes to DALYs rate of cataract, it rose by 32.18% from 65.3 per 100,000 population (95%CI: 46.4 to 88.2 per 100,000 population) in 1990 to 86.3 per 100,000 population (95%CI: 61.5 to 116.4 per 100,000 population) in 2019. For the age standardized DALY rate, it was uneven throughout the past 30 years with an overall declining trend, ending at 82.94 (95%CI: 59.06, 111.75 per 100,000 population) in 2019.

Global distribution of disease burden attributable to cataract in 1990 and 2019 and its annual change

Figure 3 shows the global distribution of prevalence of visual impairment due to cataract in the years 1990 and 2019. The countries in south Asia and south-east Asia tend to have a higher prevalence of visual impairment due to cataract in 1990 and 2019. Indonesia had the most severe disease burden in the year of 1990 (1972.50, 95%CI: 1799.04, 2158.74 per 100,000 population), while Thailand surpassed Indonesia in 2019 (3231.99, 95%CI: 2960.79, 3497.79 per 100,000 population). The annual change for prevalence of visual impairment due to cataract was positive in most countries, except for some countries located in the Middle East and Africa. As for the comparison of age-standardized prevalence of visual impairment due to cataract and DALYs rate between 1990 and 2019 among GBD super regions (Table 1), the global prevalence of visual impairment due to cataract in 2019 raised by 4.98% (95%CI: 4.86%, 5.11%) compared to that of 1990. Disease burden of most geographical regions tended to decline, with the exception of the east Asia region, whose DALYs rate increased by 14.13% (95%CI: 13.89%, 14.36%) to 967.90 (95%CI: 840.60, 1104.44) per 100,000 population in the year of 2019. The age standardized DALYs rates of 2019 among the selected GBD super regions, on the other hand, were all lower than those of 1990.

Table 1

Age-standardized prevalence of visual impairment due to cataract in 1990 and 2019 and its time trends from 1990 to 2019.

Global cataract disease burden by SDI level

The changes in age-standardized DALY rates among GBD super regions by SDI from 1990 to 2019 are given in Fig. 4. Disease burden attributable to cataract of all regions tend to decrease throughout the past 30 years, with region of higher SDI having less disease burden due to cataract. Individuals dwelling in southeast Asia and south Asia were at a higher risk of vision loss caused by cataract, whereas people in high-income North America, high-income Asian Pacific, Western Europe and Australasia were less likely to develop vision loss due to cataract.

Country-level analysis of disease burden attributable to cataract with various factors

As shown in Table 2, glaucoma and refractive error were positively associated with the disease burden of cataract, accounting for 16.95% and 14.30% of the global variation, respectively. ($P < 0.001$) Diabetes mellitus, on the other hand, did not show any association with disease burden of cataract.

Table 2
Potential associated factors for national disease burden due to cataract

Factors	Univariate linear regression			Multiple linear regression 1		Multiple linear regression 2	
	β (95%CI)	R ²	P	β (95%CI)	P	β (95%CI)	P

As for socioeconomic indicators, scatter plot with regression curve indicated that the age-standardized DALY rate of cataract was negatively correlated to SDI level (Fig. 5). In the stepwise multiple linear regression model, higher refractive error prevalence ($\beta = 0.036$, 95% CI: 0.022, 0.050, $P < 0.001$), a smaller number of physicians ($\beta = -0.959$, 95% CI: -1.685, -0.233, $P = 0.010$) and lower level of HDI ($\beta = -134.93$, 95% CI: -209.84, -60.02, $P = 0.001$) were associated with higher disease burden of cataract. Meanwhile, higher refractive error prevalence ($\beta = 0.032$, 95% CI: 0.019, 0.046, $P < 0.001$) and a smaller number of physicians ($\beta = -0.982$, 95% CI: -1.587, -0.196, $P = 0.012$) were also correlated with more severe disease burden in multiple regression model 2, together with shorter expected years of schooling ($\beta = -5.183$, 95% CI: -9.564, -0.802, $P = 0.021$).

Discussion

Our results shows that the global prevalence of visual impairment due to cataract and DALYs of cataract showed an increasing trend from 1990 to 2019, with higher burden was found in low socio-economic areas. Severer burden of visual impairment due to cataract is associated with lower SDI, lower HDI, smaller number of physicians and higher refractive error prevalence. Our findings are consistent with previous GBD studies,[9, 10] and further emphasize the importance of implementing strategies to increase coverage and reduce gaps to eliminate the rising cataract burden globally.

The crude prevalence of visual impairment due to cataract and DALYs of cataract increased steadily from 1990 to 2017, but showed a decreasing trend afterwards until 2019; this decreasing trend could more

clearly be seen in age-standardized rates (Fig. 1&2). Meanwhile, despite the increase of age-standardized prevalence of visual impairment due to cataract by 4.98% during the past 30 years, the age-standardized DALY of cataract consistently decreased (decreased by 10.98%). Taken together, this suggests a global health improvement in cataract, especially after 2017. However, the overall global burden of cataract remains high, which can be partially explained by taking into account the aging and growth of the population.

Despite the overall improvement in global cataract care, the socioeconomic disparity in cataract burden is a major challenge for reducing global cataract blindness. Previous studies have reported higher cataract prevalence and lower cataract surgical rates in developing and un-developed countries.[22] The GBD Studies have also reported consistently increasing socioeconomic-associated inequality in global cataract burden in the last decades.[10] In our study, the age-standardized prevalence of visual impairment due to cataract was highest in low-middle SDI regions and lowest in high SDI regions in both 1990 and 2019. The greatest declines in age-standardized DALYs rate of cataract between 1990 and 2019 were in Southern sub-Saharan Africa, Andean Latin America and Southeast Asia, while the greatest increase was in East Asia and Western sub-Saharan Africa. With more than 20% of the total world population, the East Asia regions contribute to largest increase in cataract burden and are in urgent need for future effective strategies to combat the upcoming increasing challenge of cataract burden. Additionally, the age-standardized DALYs of cataract in 2019 were significantly reduced in all regions as compared to 1990, with the greatest decline seen in Low-middle SDI regions. The percentage change in age-standardized DALY was largest in Southern sub-Saharan Africa, North Africa and Middle East, and Andean Latin America (all over 30%). In comparison, the decreases in East Asia and Western sub-Saharan Africa were only modest (10.22% and 8.14%), and below the average global decreasing level.

Consistent with previous studies, our study showed that lower number of physicians and less education were significant risk factors for higher cataract burden.[23–25] It is noteworthy that higher refractive error prevalence was also found to be positively related to a higher national disease burden due to cataract, even after adjusting for all other covariates. One possible reason may lie in that with the increasing prevalence of refractive error, the complex cataract cases due to myopia increase.[26] Various studies have found that individuals with high myopia are more likely to develop cataract.[26, 27] The Blue Mountains Eye Study found that even participants with low myopia (-1 to -3.5D) had higher risk of posterior subcapsular cataract.[28] A meta-analysis reported that myopia was associated with a higher risk of nuclear and posterior subcortical cataract.[29] However, advances in surgical techniques for cataract, coupled with improvements in intraocular lens design and the increased availability of low-cost, high-quality intraocular lens, have led to significant improvements in patient accessibility and surgical outcomes. In the last decades, the increase in the prevalence of visual impairment due to cataract and its associated disease burden warrants further investigation and monitoring of cataract on a national and global basis, as well as the identification of determinants for further increase. Implementation of currently known and effective treatments of cataract are expected to contribute significant productivity gains to the global economy at a fraction of the estimated costs to deliver them.[30] Increasing the quantity and quality of cataract surgery services, and tailored blindness-prevention programs to meet the needs of

local population and resources remains the most important solutions to the existing and impending cataract burden.

The present study provides stakeholders with estimates at regional and global level over 20 years to help monitor the effectiveness of interventions regarding cataract through time. However, some limitations should be noted. The study was subject to the limitations that the GBD 2019 study had noted in their reports, including statistical assumption and data sources.[12, 31] Specifically for cataract, the use of aggregated data at a country level would be a source of bias, due to geographic variations in DALY estimates. In addition, potential associated factors for cataract burden including cost, ophthalmologist numbers, facilities and surgical quality were not available, [25, 32] and future studies investigating these important determinants for cataract burden can provide a more comprehensive assessment and support for strategic planning.

Conclusion

In summary, cataract is still an important contributor to global disease burden which is likely to continue to pose a great challenge in health care with population aging and growth. Successful global initiatives targeting improving cataract surgical rate and quality, especially in regions with lower socioeconomic status, is a prerequisite to combating this growing burden of cataract in the aging society.
