Version of Record: A version of this preprint was published at BMC Endocrine Disorders on April 7th, 2022. See the published version at https://doi.org/10.1186/s12902-022-01006-6.

Abstract

Background: The efficacy of liraglutide to treat type 2 diabetic nephropathy (T2DN) remains controversial. Thus, we conducted this meta-analysis to systematically evaluate the clinical effect of liraglutide on T2DN patients.

Methods: Eight databases (PubMed, Web of Science, the Cochrane Library, EMBASE, Chinese National Knowledge Infrastructure (CNKI), Wanfang database, China Science and Technology Journal Database and China Biology Medicine Database (CBM)) were searched for published articles to evaluate the clinical efficacy of liraglutide in subjects with T2DN. The Revman 5.3 and Stata 13 softwares were used for analyses and plotting.

Results: A total of 18 randomized controlled trials (RCTs) with 1580 diabetic nephropathy patients were screened. We found that the levels of UACR, Scr, Cysc were lower in experimental group of T2DN patients treated with liraglutide than control group intervened without liraglutide. Liraglutide also reduced the levels of blood glucose (including FBG, PBG and HbA1c), body mass index (BMI), and anti-inflammatory indicators (TNF-α, IL-6). However, there was no significant difference in BUN and eGFR between experimental group and control group.

Conclusions: Liraglutide reduced the levels of Blood Glucose, BMI, renal outcome indicators and serum inflammatory factors of patients with T2DN, suggesting the beneficial effects of liraglutide on renal function.

1. Background

Although primary prevention for risk factors and early intervention in the levels ofblood glucose effectively reduce the rates of incidence and renal failure caused by type 2 diabetic nephropathy (T2DN), T2DNis still one of the most serious and prevalent microvascular complication of diabetes mellitus with type 2 (T2DM) worldwide [1]. The number of adult diabetes patients in the world obtained from the report of international diabetes federation is about 463million (approximately 9.3% of the world population) by the end of 2019, which is expected to reach 578.4million (10.2%) by 2030 and 702million (10.9%) in 2045 [2]. Unfortunately, more than 40% of the individuals with diabetes mellitus will develop kidney disease over time [3]. Obviously, the morbidity of T2DM is exceedingly high, and an increasing number of T2DN cases are relatively detected. In fact, T2DN has become the major cause leading to end-stage renal disease (ESRD) [4].

For a long time in the past, a wide variety of drugs such as insulin, metformin, sulfonylurea, meglitinide and thiazolidinedione were utilized to control the level of blood glucose and reduce the risk of diabetic complications [5]. However, substantial adverse effects associated with these traditional drugs including hypoglycemia and weight gained and drugs-resistance lead to the limitation of drug application. Fortunately, a new kind of compounds glucagon-like peptide 1 receptor agonists (GLP-1RA) have been increasingly used on treatments of diabetes and its complications in recent years. Liraglutide, a common GLP1-RA, shows good curative effect in reducing weight and controlling blood glucose [6, 7]. Furthermore, a significant contribution of liraglutide on the renoprotective is to be expected.

Some previous studies have shown that liraglutide can reduce urine protein and has a renal protective effect [8, 9]. But some others did not find the same results [10]. In conclusion, the efficacy of liraglutide to treat T2DN remains controversial. Thus, the aim of this meta-analysis is to estimate the efficacy of liraglutide in the treatment of T2DN and which related indicators may be affected.

2. Materials And Methods

2.1 Search Strategy

Health-related electronic databases including PubMed, Embase, Web of Science, the Cochrane Library, CNKI, Wanfang database, VIP and CBM Database, were searched to identify eligible studies to July 2021 inclusive, using the following Medical Subject Heading (MeSH) AND/OR entry words in any field, "diabetic nephropathy", "diabetic nephropathies", "proteinuria", "diabetic kidney disease", "albuminuria", "liraglutide", "diabetic glomerulosclerosis", "urinary albumin excretion", "type 2 diabetes mellitus". Correspondingly, search strategy was slightly adjusted according to the range of the search results in different databases. In addition, the related research were limited to RCT published in English or Chinese language. In order to avoid missing other relevant articles, We also manually retrieved the references of every articles and relevant reviews to investigate any additional eligible studies.

2.2 Inclusion Criteria

Study inclusion criteria were as follows:

- 1. studies performed as randomized controlled trials;
- 2. studies that involved type 2 DM patients with nephropathy;
- 3. studies that included patients who were under a controlled diet and exercise therapy, some of them were treated with anti-hypertensive drugs or other anti-hyperglycemic treatments (control group), and the others treated with liraglutide (experimental group);
- 4. studies that reported renal function outcomes, including estimated glomerular filtration rate (eGFR); urine albumin creatinine ratio (UACR); Blood Urea Nitrogen (BUN); serum creatinine (Scr) [Iserum cystatin C (CysC);

2.3 Data extraction

Based on the inclusion and exclusion Criteria, all screened studies were independently identified by two reviewers (MN and SF). Notably, any discrepancy between the two reviewers was resolved by discussion or the third reviewer (FWX). Then, the selected full-text articles were performed eligibility evaluation to determine whether them were suitable for the current meta-analysis. Furthermore, the information extracted from each study included:

- 1. the general information, comprising the name of the first author, the year of publication, type of trial, total number of patients, gender composition, average age of patients in the experimental group and the control group, the therapeutic approaches, course of treatment.
- 2. the evaluation index of outcome included: hypoglycemic related indicators (FBG@PBG@HbA1c) and BMI; renal function (UACR@Scr@CysC@BUN@eGFR); anti-inflammatory indicators (IL-6@TNF-α).

2.4 Assessment of quality of evidence

The quality evaluation for every selected articles was independently assessed by two authors (MN and SF) using the Cochrane Collaboration's tool for assessing risk of bias [11]. In general, the evaluation contents included the quality appraisal of the literature comprised random sequence generation (Selection Bias), allocation concealment (Selection Bias), blinding of participants and personnel (Performance Bias), blinding of outcome assessment (Detection Bias), incomplete outcome data (Attrition Bias), and selective reporting (Reporting Bias), and other sources of bias. Similarly, disagreements for the risk of bias by two investigators were resolved by discussing or the third reviewer. Markedly, articles that had clearly defined details and met or surpassed the quality criteria were defined as lowrisk; if not, they were deemed highrisk. Ambiguous articles in relations of quality criteria remained deemed to be of unclear risk. Notably, the quality of trials were evaluated by means of the Cochrane Collaboration's Tool for evaluating risk of bias in randomized controlled trials; quality was not used as a standard for the selection of trials, however merely for descriptive purposes.

2.5 Data analysis

Review Manager Software 5.3.5 (RevMan 5.3.5) and Stata 13 Software were used for all data analyses and plotting. The Chi-Squared-based Q-tests and I-squared (I2) statistic were utilized to evaluate the statistical heterogeneity of the included studies [12]. The value of I2 test greater than 50% and $p \le 0.05$ were regarded as substantial heterogeneity. Then DerSimonian-Laird random-effect model [13] was performed, otherwise, a Mantel-Haenszel fixed-effect model [14] was conducted. Subsequently, the statistical significance of Standardized Mean Difference (SMD) or Weighted Mean Difference (WMD), and 95% confidence intervals (95% CIs) were estimated by Z tests. In addition, the symmetry of funnel plots was applied to determined the publication bias of the selected studies [15]. Sub-group analyses were carried out by HbA1c and ACR due to significant heterogeneity across the included studies.

3. Results

3.1 Literature search and selection

A total of 740 articles including 736 records from the electronic databases using different search strategies and 4 articles through literature tacking and reading were identified. After removing 481 duplication and 450 records unmet the inclusion criterion, 31 studies were selected to further verify through full-text reading. In the residual records, 13 full-text articles were excluded with reasons (n = 13) as follows: 2 trials are not RCT, 3 articles trials no full text could be found to extract data, 2 lack of renal outcomes data, 6 control groups are not DN with type 2. Finally, 18 articles satisfied the inclusion criteria were included in the metaanalysis. The article search and study selection process were displayed in Fig. 1.

3.2 Characteristics of eligible studies

In our meta-analysis, all of the selected studies were published during 2014 to 2020. In detail, 18 studies [16–33] included 1580 DN patients enrolled in the study, of which 786 in the liraglutide group and 794 in the control group. Among these studies, 12 articles [17–21, 23, 24, 26–28, 30, 32, 33] illustrated the average age of patients with T2DN and the ratio of sex, while only 5 RCTs [17, 20, 23, 26, 32] showed the course of disease in patients with T2DM. Besides, in the liraglutide group, liraglutide were given duration 4 to 24 weeks with dosage 0.6 to 1.8 mg/day. However, kinds of drugs from different studies included trials placebo, routine treatment, Huangkui capsules, nephritis rehabilitation tablets, insulin or active comparators (metformin, glimepiride and glargine) were used in the control group. The detailed characteristics of the included studies were listed in Table 1.

3.3 Risk of bias

The Cochrane Collaboration's tool was used to evaluate the quality of the individual studies based on the randomization, allocation hiding, blinding, publication bias, etc. Among 18 studies, 14 of them described as randomized trials (5 of which were random number table method), 1 study was grouped according to the patient's wishes, 2 studies were grouped according to the patient's original treatment, and the last one article was not mentioned the method of grouping. For allocation concealment, 4 studies were not mentioned, and 3 studies may have higher allocation hidden risk. In addition, one trial was single-blind experiment, and the others were not indicated the method of blinded. Unfavorably, one article had incomplete primary outcome indicators and selective-publication possibility. Notably, no other bias factor was found in all articles. The specific quality evaluation chart was shown in Fig. 2A-B.

4. Effect Of Interventions

4.1 Relationship of liraglutide with renal function

In order to estimate the effect of liraglutide on renal function in patients with T2DN, the statistic differences of eGFR, BUN, Scr, UACR and CysC between the liraglutide group and the control group were calculated and visualized by forest maps. The results of our meta-analysis suggested that there were significant differences between the liraglutide group and the control group in the levels of Scr (SMD=-0.81, 95% CI: [-1.22,-0.4], p < 0.0001) (Fig. 3A, Table 2), UACR (SMD=-2.34, 95% CI: [-3.65, -1.03], p = 0.0005) (Fig. 3B, Table 2) and CysC (WMD or MD=-0.70, 95% CI: [-1.01, -0.39], p < 0.0001) (Fig. 3C, Table 2) after treatment. However, no differences between the liraglutide group and the control group were detected in the levels of BUN (WMD=-1.06, 95% CI: [-2.22,0.10], p = 0.07) (Fig. 3D, Table 2) and eGFR(WMD=-0.81, 95% CI: [-1.22, -0.40], p = 0.21) (Fig. 3E, Table 2) .In summary, liraglutide greatly reduced the levels of UACR, Scr and Cysc compared with treatment without liraglutide.

Table 2 Study findings summary

Outcome	Number of study	Sample	Heterger	neilty		Analysis model	Statistical method	WMD/SMD (95% CI)	P value
	Study	Test/Control	χ²	 2	Р	- Illouei	method	CI)

Scr	11	531/532	94.16	89%	< 0.00001	Random- effects	Inverse Variance	-0.81[-1.22,-0.4]	< 0.0001
CysC	2	32/39	0.44	0%	0.5	Fixed-effects	Inverse Variance	-0.7[-1.01,-0.39]	< 0.0001
IL-6	5	248/248	130.43	97%	< 0.00001	Random- effects	Inverse Variance	-2.03[-3.30,-0.77]	0.002
TNF-α	6	303/303	38.24	87%	< 0.00001	Random- effects	Inverse Variance	-1.16[-1.66,-0.66]	< 0.00001

4.2 Relationship of liraglutide with hypoglycemic related indicators and BMI

For validating the influence of liraglutide on hypoglycemic related indicators and BMI in patients with T2DN, the statistic differences of FBG, PBG, HbA1c and BMI between the liraglutide group and the control group were estimated. As shown in the Fig. 4A and Table 2, the patients in the liraglutide group measured lower levles of FBG (WMD=-0.66, 95% CI: [-1.04,-0.27], p = 0.0009) (Fig. 4A, Table 2), PBG (WMD=-1.51, 95% CI: [-1.68,-1.34], p < 0.00001) (Fig. 4B, Table 2), HbA1c (WMD=-0.61, 95% CI: [-0.95,-0.27], p = 0.0004) (Fig. 4C, Table 2) and BMI (WMD=-2.27, 95% CI: [-2.98,-1.56], p < 0.00001) (Fig. 4D, Table 2) than patients in the control group, suggesting the excellent performance in controlling blood sugar and weight loss of liraglutide.

4.3 Relationship of liraglutide with anti-inflammatory indicators

In order to further confirm whether the liraglutide could reduce inflammatory reaction and thus prevent renal fibrosis, we compared the levels of IL-6 and TNF- α between the liraglutide group and the control group after drug intervention. Notably, liraglutide was demonstrated delay the process of renal fibrosis by antiinflammatory in our analysis. Obviously, the liraglutidegroup was detected lower levles of TNF- α (SMD=-1.16, 95% CI: [-1.66,-0.66], p<0.00001) (Fig.5**A, Table2**) and IL-6 (SMD=-2.03, 95% CI: [-3.30,-0.77], p=0.002) (Fig.5**B, Table2**) than control group.

4.4 Sensitivity analysis and evaluation of publication bias

In order to verify the sources of heterogeneity, sensitivity analysis byremoving each study gradually was performed using Stata 13 software. The result showed that when removing the studies of Zhengyan [25] and Aiyitan [27], obvious changes of pooled WMD were found (Fig.6A). Therefore, we considered the heterogeneity coming from these two studies. Morever, funnel plots drawn through Revman software was used to display publication bias. Asymmetry was detected in Fig.6B-C, suggesting that there may be publication bias, and the results that are not statistically significant may not be published.

5. Discussion

DN is one of the complications of DM. The pathogenesis of DN is linked to various factors, including metabolic and hemodynamic abnormalities [34]. Some studies have shown that GLP-1RA can reduce proteinuria and improve renal function. The mechanism may be that GLP-1RA induce NHE3 (Na+/H+exchanger 3-) phosphorylated and activated, which can result in the reabsorption of filtered Na+increase in proximal tubule [35–36], which may improve renal hemodynamics in diabetes-associated glomerular hyperfiltration through overlapping and separate mechanisms, then helps to reduce albuminuria. Liraglutide also alleviated the accumulation of glomerular extracellular matrix (ECM) and renal injury in DN by improving the

signaling of Wnt/β-catenin. The Wnt/β-catenin signaling pathway is involved in mesangial cell production of ECM (MCs). Treatment with liraglutide significantly reduced high glucose (HG)-stimulated production of fibronectin (FN), collagen IV (Col IV) and alpha-smooth muscle actin (alpha-SMA) in cultured human mesangial cells (HMCs) and significantly attenuated the liraglutide effects with XAV-939, a selective Wnt/β-catenin signaling inhibitor [37]. In addition, Our results have showed that liraglutide can reduce urinary protein indicator of UACR and renal function indicators including Scr and Cysc, which also confirm these points. But GLP-1RA has no clinically important effect on SUN and eGFR, which may be due to the insufficient number of RCT included.

With regard to blood glucose and BMI, liraglutide decreased BMI and blood glucose levels in the current meta-analysis [38]. The hypoglycemic mechanism of liraglutide relies on it can increase insulin secretion and alpha beta cell action to inhibit glucagon release, which lead to decreased plasma glucose in diabetes patients, and the role of central nervous receptors to increase satiety, delayed gastric emptying [39]. Our results also show that liraglutide can decrease the level of blood glucose, BMI.

In the development of DN, NF-kB plays a central role in the inflammatory pathway [40]. Regulated nuclear factor kappa-b NF-kB activation and subsequent inflammatory response in mesangial cells is involved in the hyperglycemia-induced downregulation of GLP-1R [41]. In this meta-analysis, the results also showed that, in the liraglutide group, the down-regulated TNF-a and IL-6 levels were better than in the control group. Although the number of studies we included was small, liraglutide was shown to have an anti-inflammatory effect on the kidney in conjunction with previous studies.

The following limitations exist in this study. No blind method was used in all the studies. As a result, the quality of the included literature declined relatively and there exist implementation bias. The inconsistency in baseline data, treatment base measures and experimental protocols of Zhengyan's and Aiyitan's study led to heterogeneity according to our sensitivity analysis.

6. Conclusion

liraglutide appears to be effective in decreasing urinary protein, improving renal function, improving blood glucose levels and producing antiinflammatory effects in patients with DN. In order to further investigate the effects of GLP-1RA liraglutide on ESRD in the future, and provide
evidence-based medical information to prove clinical safety and rational drug usage, RCTs from more centers and large sample randomized doubleblind controlled trials are needed due to certain limitations. Thus, liraglutide therapy of patients with type 2 diabetes has beneficial effects on kidney
outcomes. Such findings support the advantages of using liraglutide for clinical use.
