Abstract

We performed zircon U–Pb dating on the Pliocene Tanigawa-dake granites (Makihata and Tanigawa bodies) and the Cretaceous Minakami quartzdiorite, Northeast Japan Arc. Concordia ages were estimated to be 3.95 ± 0.11 Ma (± 2 sigma) for the Makihata body, 3.18 ± 0.13 Ma and 3.32 ± 0.15 Ma for the Tanigawa body, and 109.4 ± 2.2 Ma for the Minakami quartzdiorite. The Minakami quartzdiorite is possibly correlated to the bedrock in the Ashio belt because the age of the Minakami quartzdiorite is consistent with the zircon U–Pb ages of the earliest Tadami-gawa granites (107–62 Ma) which are distributed to the northeast of the Tanigawa-dake region and belong to the Ashio belt. All the zircon U–Pb ages of the Tanigawa-dake granites are older than the previously reported cooling ages, i.e., K–Ar ages and zircon fission-track ages, being consistent with their difference in closure temperature. On the basis of these results, we concluded that the intrusive ages of the Tanigawa-dake granites are ~4–3 Ma, which are among the youngest exposed plutons on Earth. The U–Pb ages of the Makihata body and the Tanigawa body are different significantly in the 2 sigma error range. Thus, the Tanigawa body intruded later than the Makihata body by ~0.7 Myr.

Introduction

Granites are formed generally at a crustal depth of a few to dozen kilometers. Therefore, the regions where young granites are exposed must have been uplifted and denuded at an extraordinary high rate. Granites younger than ~5 Ma have been discovered basically along convergent plate boundaries (Harayama, 1992). In the Japanese Islands, such young granites have been reported along arc-arc junctions in central Japan based on zircon U–Pb dating, e.g., 10–0.8 Ma in the Hida range, Northern Japan Alps (Ito et al., 2013) and ~4 Ma in the Tanzawa mountains, Izu collision zone (Tani et al., 2010). The Tanigawa-dake region, southern end of the Northeast Japan Arc, can also involve young granites (Sato, 2016) considering the young cooling ages (Ganzawa and Kubota, 1987; Kawano et al., 1992; Ohira and Honda, 1999; Kubo et al., 2013; Sato, 2016) although this region is located away from the arc-arc junctions. For instance, Rb–Sr age of whole rock is estimated to be 5.27 ± 1.28 Ma representing formation age of the granite (Ohira et al., 1998, 1999). Biotite K–Ar ages are 3.9–3.1 Ma (Kawano et al., 1992; Sato, 2016), whose closure temperature is 350–400°C (Harrison et al., 1985; Grove and Harrison, 1996). Zircon fission-track ages are 3.3–2.9 Ma (Ohira and Honda, 1999), whose closure temperature is 250–350°C (Yamada et al., 2007; Ketcham, 2019). However, the previous studies have two problems to estimate the intrusive age: 1) Rb–Sr age was obtained only from a single locality and has a large error, and 2) biotite K–Ar ages and zircon fission-track ages are cooling ages, probably younger than the intrusive ages. Thus, this study aims to estimate the reliable intrusive ages. We collected samples from the intrusive bodies and applied zircon U–Pb dating, as well as the late Cretaceous granites intruded by the young plutons.

Geology And Sampling

The Tanigawa-dake area is located on the back-arc side of the Northeast Japan Arc. Mt. Tanigawa-dake (1,977 m high) is a non-volcanic mountain surrounded by Quaternary volcanoes, such as, Mt. Naeba, Mt. Iiji and Mt. Hotaka (Fig. 1). Coastal areas of the Sea of Japan, including the Tanigawa-dake area, is one of the heaviest snow areas in the world (e.g., Ueda et al., 2015; Kawase et al., 2018, 2020). In addition, glacial landforms formed at the last glacial period are distributed in the Tanigawa-dake and adjacent mountains (Koaze, 2002). Therefore, although the uplift mechanism is not well-known, the Tanigawa-dake region is expected to be denuded rapidly enough to expose the Pliocene plutons.

Lithology of the Tanigawa-dake area consists mainly of Cretaceous to Paleogene granitoids, late Miocene to Pliocene granitoids, and Miocene to Quaternary volcanic rocks (Sato, 2016: Fig. 1). The late Miocene to Pliocene granites are called the Tanigawa-dake granites, being subdivided into three bodies, i.e., the Makihata body, the Tanigawa body, and the Akayu body, from east to west (Chihara et al., 1981). The Makihata body and the Tanigawa body are exposed on the eastern and western sides of Mt. Tanigawa-dake, respectively. The Akayu body is distributed on the southern side of Mt. Naeba. The late Cretaceous plutonic rock is called the Minakami quartzdiorite (Kubo et al., 2013; Sato, 2016) which is distributed to the southeast of Mt. Tanigawa-dake. In the previous studies, these rocks were dated based on fission-track dating of zircon and apatite, K–Ar dating of biotite and whole rock, and Rb–Sr dating of whole rock. The biotite K–Ar (3.9–3.1 Ma; Kawano et al., 1992; Sato, 2016) and zircon fission-track ages (3.3–2.9 Ma; Ohira et al., 1998; Ohira and Honda, 1999) are consistent with each other within error range of 2 sigma regardless of location. Therefore, the Tanigawa-dake granites were cooled uniformly at ~250–400°C. However, thermal histories above the temperature range were not well-known, including the timing of the intrusive of the Tanigawa-dake granites. In this study, for obtaining clearly intrusive ages of the Tanigawa-dake granites and intruded granites, we collected 4 rock samples: TNG20-03 and TNG20-10 from the Tanigawa body, TNG20-05 from the Makihata body, and TNG20-09 from the Minakami quartzdiorite (Fig. 1, Table 1).

U–pb Zircon Dating Method

Zircon grains were separated from the granitoid samples by crushing, sieving, panning, magnetic separation and heavy liquid techniques. The zircon grains were mounted in resin (SpeciFix, Struers ApS, Denmark) and then used for Cathodoluminescence observation and U–Pb isotopic analysis using field-emission electron probe microanalyzer (FE-EPMA, JEOL JXA-8530F) and multiple collector inductively coupled plasma mass spectrometer (Neptune-Plus, Thermo Fisher Scientific, Bremen, Germany) with an excimer laser system (Analyte G2; Photon Machines, Redmond, WA, USA) (LA-MC-ICP-MS), respectively, at Tono Geoscience Center, JAEA. Elemental fractionation and instrumental mass bias on $^{206}\text{Pb}/^{238}\text{U}$, $^{207}\text{Pb}/^{206}\text{Pb}$ ratios were corrected using the measured isotope ratio of the 91500 zircon (Wiedenbeck et al., 1995) as primary standard with a standard-sample bracketing approach. The OD-3 zircon (Iwano et al., 2013) was used as secondary standard material for age quality control. The details of analytical setting are summarized in Table S1. The zircon grains were measured for each of the 4 samples, and the results are summarized in Table 1 (for the details, see also Table S2). In this paper, the data were defined

as 'concordant' when overlapping the concordia curve on a concordia diagram within error range of 1 sigma. Isoplot software ver. 4.15 (Ludwig, 2012) was used to produce the concordia diagrams and the concordia ages (2 sigma-weighted mean age of $^{207}\text{Pb}/^{235}\text{U}$ and $^{206}\text{Pb}/^{238}\text{U}$ isotopes; Ludwig, 1998) using the 'concordant' data (Fig. 2).

Table 1. Summary of dating results

Body name	Sample	Lithology	Locality		U-Pb Ages (Ma)		
			Longitude	Latitude	Concordia Age	± 2 sigma	Number of grains
Tanigawa	TNG20-03	Granodiorite	138°47'39.93"E	36°48'28.31"N	3.18	0.13	29
Makahata	TNG20-05	Granodiorite	138°57'7.45"E	36°50'27.19"N	3.95	0.11	30
Minakami	TNG20-09	Quartzdiorite	138°58'34.44"E	36°47'6.50"N	109.4	2.2	29
Tanigawa	TNG20-10	Granodiorite	138°52'16.74"E	36°52'5.04"N	3.32	0.15	20
	OD-3				33.4	2.8	5
	OD-3				33.1	1.8	5
	OD-3				32.9	2.1	3
	OD-3				32	2	3

The reference age of OD-3 is 33.0 ± 0.1 Ma (± 2 sigma) (Iwano et al., 2013).

Results And Geo-/thermo-chronologic Interpretation

Summaries of the dating results are shown in Table 1 and Figure 2. Zircon U–Pb ages of OD-3 (secondary standard) were computed to be 33.4 ± 2.8 (± 2 sigma Ma), 33.1 ± 1.8 (± 2 sigma) Ma, 32.9 ± 2.1 (± 2 sigma) Ma, 32.0 ± 2.0 (± 2 sigma) Ma. These ages are consistent with the reference age (33.1 ± 0.1 Ma, 2 sigma; Iwano et al., 2013) within the 2 sigma error range.

The concordia ages were calculated from 30 zircon grains for TNG20-05, 29 zircon grains for TNG20-03 and TNG20-09, and 20 zircon grains for TNG20-10. One discordant grain was identified in TNG20-03 and TNG20-09, respectively, which was removed from the concordia age calculation. Consequently, the concordia ages were calculated to be 3.18 ± 0.13 (± 2 sigma) Ma for TNG20-03, 3.95 ± 0.11 (± 2 sigma) Ma for TNG20-05, 3.32 ± 0.15 (± 2 sigma) Ma for TNG20-10 and 109.4 ± 2.2 (± 2 sigma) Ma for TNG20-09.

The zircon U–Pb ages obtained in this study were compared with the reported cooling ages, i.e., K–Ar ages of biotite and fission-track ages of zircon. The comparison did not include the Rb–Sr age of whole rock and K–Ar age of whole rock because the sampling point of Rb–Sr age is unknown and the closure temperature of the two dating methods cannot be defined. The reported ages of the Tanigawa-dake granites are 3.9–3.1 Ma based on biotite K–Ar dating (Kawano et al., 1992; Sato, 2016) and 3.3–2.9 Ma based on zircon fission-track dating (Ohira et al., 1998). The obtained zircon U–Pb ages are consistent with the reported ages given the higher closure temperature (>900°C; Cherniak and Watson, 2000). Namely, zircon U–Pb ages are coincident with or older than the reported ages close to each sampling locality within the error range of 2 sigma.

For the Minakami quartzdiorite, the K–Ar age of whole rock was estimated at ~70 Ma (Kubo et al., 2013), which is the only geochronologic datum reported previously. The zircon U–Pb age is older than the K–Ar age of whole rock by 40 Myr.

Geological Implication

Based on the U–Pb age of TNG20-09, the Minakami quartzdiorite might be correlated with the Tadamigawa granites. The Tadamigawa granites is located to the northeast of Mt. Tanigawa-dake, belonging to the Ashio belt. The Minakami quartzdiorite age is consistent with the oldest zircon U–Pb age of the Tadaimigawa granites (106.7 ± 0.6 Ma; 95% confidence interval: Wakasugi et al., 2020) within the error range of 2 sigma. As a result, the igneous activity to form the Minakami quartzdiorite is compared to the first igneous event to form the Tadamigawa granites. Namely, the Minakami quartzdiorite can be an associated body as the bedrock distributed in Ashio belt.

According to zircon U–Pb ages of TNG20-03, TNG20-05 and TNG20-10, the Tanigawa body is considered to have intruded after the Makihata body. The intrusion age for the Tanigawa body was estimated to ~3.3–3.2 Ma because the zircon U–Pb ages of TNG20-03 and TNG20-10 in the Tanigawa body are consistent within error range of 2 sigma. On the other hand, zircon U–Pb age of the Makihata body, TNG20-05, is significantly older than those of the Tanigawa body with error range of 2 sigma. Therefore, the Tanigawa-dake body could have intruded 0.7 Myr later than the Makihata body. The Tanigawa-dake granites were estimated to be formed by at least two magmatism.

On the other hand, the previously reported cooling ages, i.e., biotite K–Ar ages and zircon fission-track ages, are not significantly different for Makihata and Tanigawa bodies despite the different intrusive ages. The possible two reasons follow below: 1) the biotite K–Ar and zircon fission-track ages of the Makihata body were reset by the thermal effect of the intrusion of the Tanigawa body, and 2) the Makihata body was more slowly cooled than the Tanigawa body from the intrusion to ~250–400°C. In either case, the Tanigawa body and the Makihata body might have experienced different cooling histories above ~400°C.

Conclusion

To determine the intrusive ages, a sequence of zircon U–Pb dating was performed for the Pliocene granites at 3 localities and late Cretaceous quartzdiorite at 1 locality in the Tanigawa-dake area. The ages of the Tanigawa body are 3.18 ± 0.13 (± 2 sigma) Ma for TNG20-03 and 3.32 ± 0.15 (± 2 sigma) Ma for TNG20-10, the age of the Makihata body is 3.95 ± 0.11 (± 2 sigma) Ma for TNG20-05, and the age of the Minakami quartzdiorite is 109.4 ± 2.2 (± 2 sigma) Ma for TNG20-09. From these results, the age of the Minakami quartzdiorite is considered to correspond to the Tadami-gawa granite, bedrock of the Ashio belts. Additionally, the Makihata body intruded earlier than the Tanigawa body by 0.7 Myr. Thus, the Tanigawa-dake granites are estimated to be formed by at least two times of magmatism, being among the youngest plutons exposed on Earth.

Figures

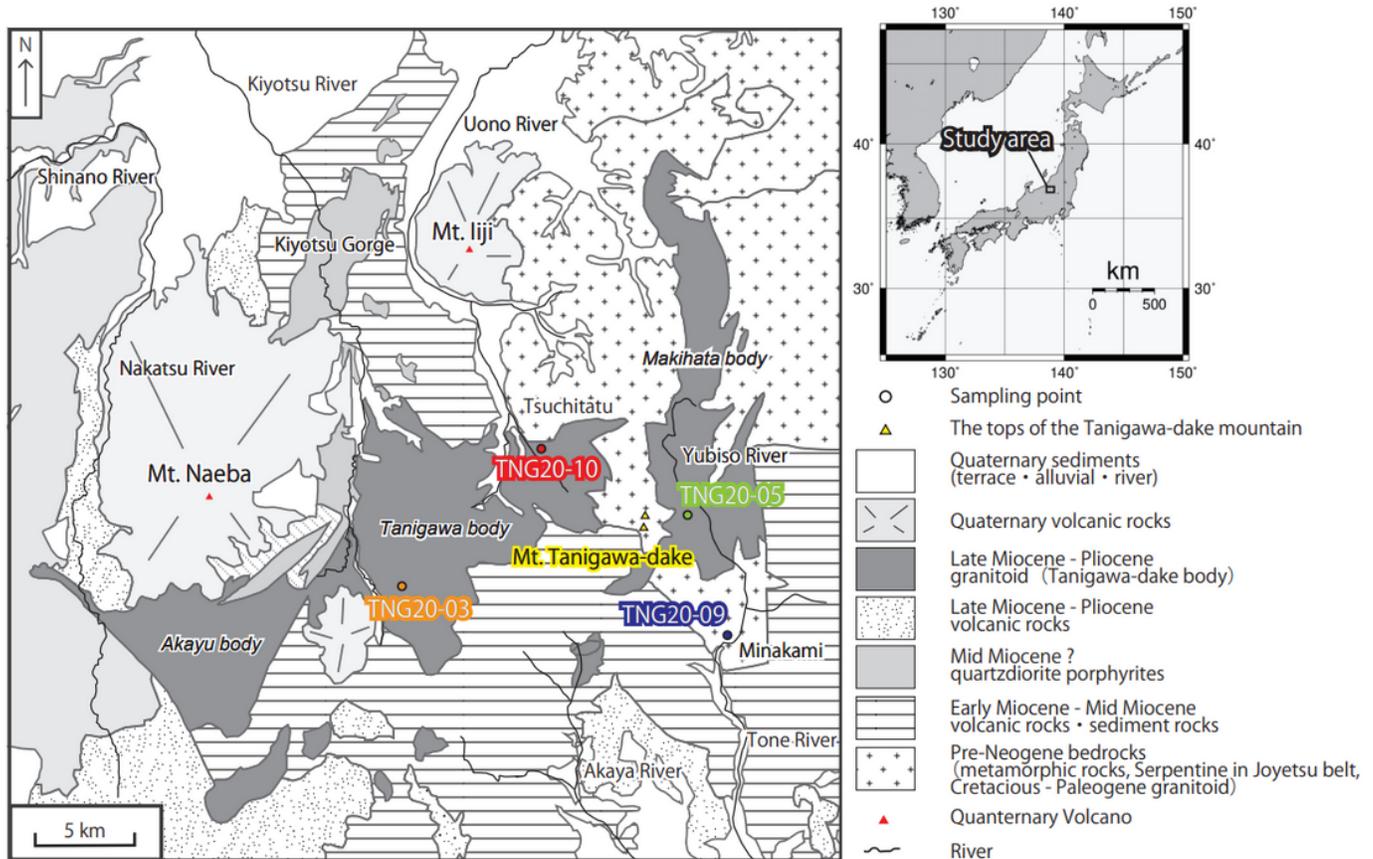

Figure 1

Index map of the study area. The geologic map was modified from Sato (2016) and Geological Survey of Japan web page (<https://gbank.gsj.jp/geonavi/geonavi.php#11,36.83525,138.87626>). Circle points denote sampling localities.

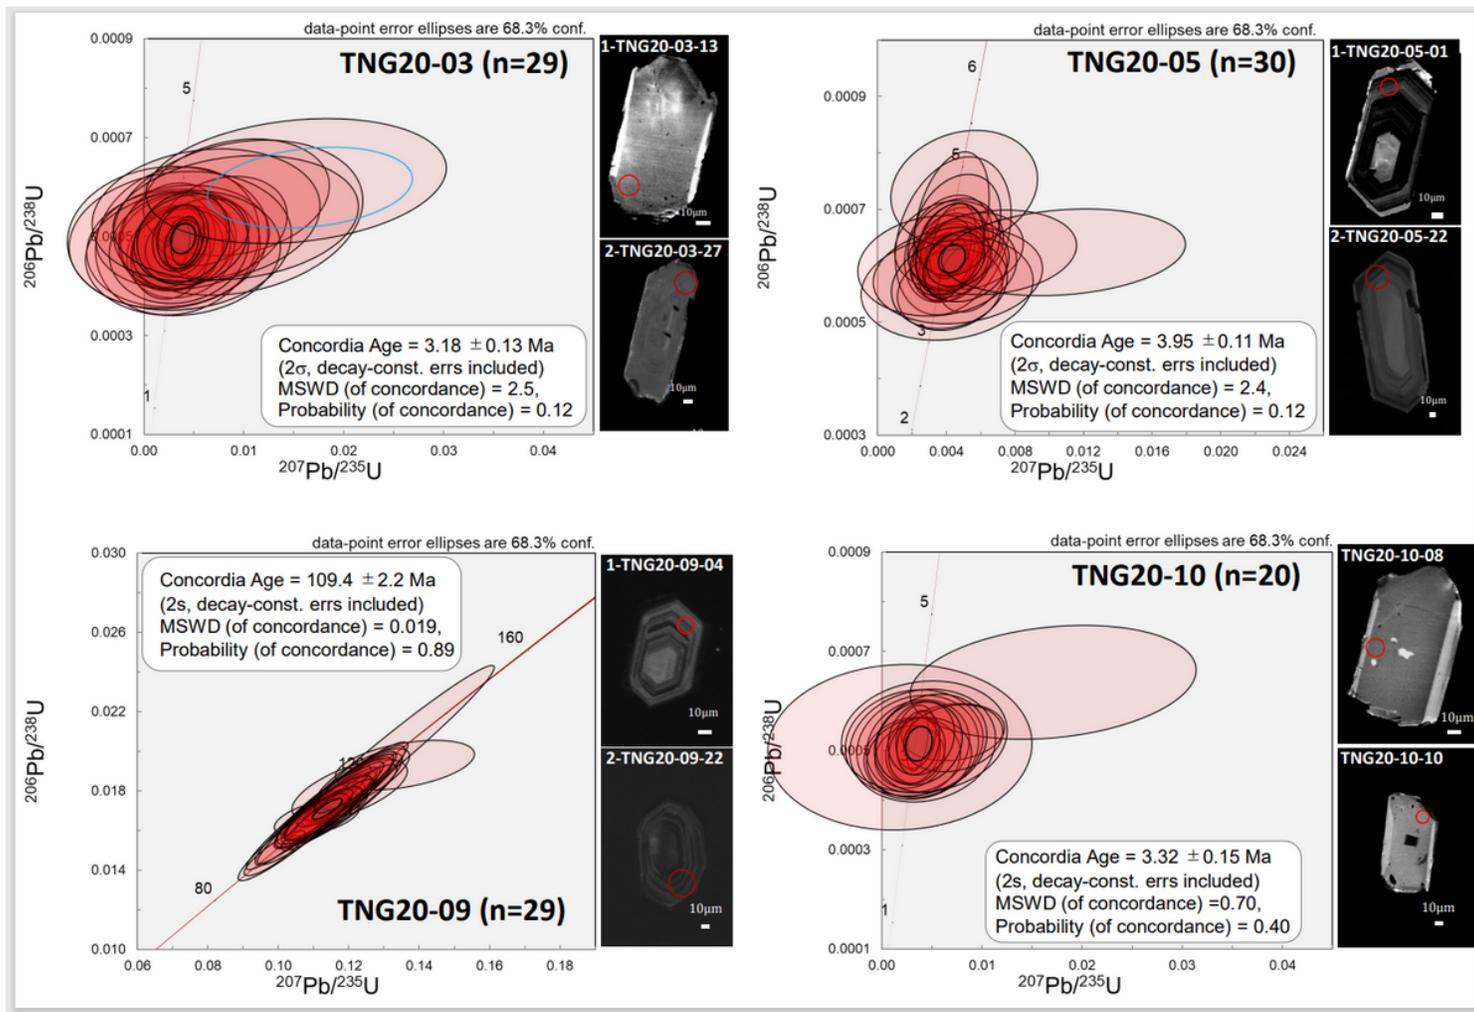

Figure 2

The concordia diagrams and the cathodoluminescence images. The diagrams were drawn by using Isoplot 4.15 (Ludwig, 2012). In concordia diagrams, red solid and blue open circles indicate concordant and discordant dates within the error range of 1 sigma, respectively. The heavy line circles are the concordia ages with 2 sigma errors, calculated from the concordant data. The discordant data of TNG20-09 is not displayed because it is far away from the concordant curve. The measurement spots (red open circles) are shown in the cathodoluminescence images showing the growth structure of zircon.
