Abstract

The relationship between the expression of the SATB2, CDX2, and p53 proteins and common molecular changes in colorectal cancer (CRC) has rarely been studied. Recent literature suggests that the loss of SATB2 and CDX2 expression is more frequently observed in cases of colon cancer with DNA mismatch repair (MMR) protein deficiency and *BRAF* mutation. We collected 1180 cases of CRC and explored the association between the expression of SATB2, CDX2, and p53 and clinicopathological characteristics and molecular alterations of CRC using whole-slide immunohistochemistry. Our results showed that negative expression of SATB2 and CDX2 was more common in MMR-protein-deficient CRC than in MMR-protein-proficient CRC (15.8% vs. 6.0%, $P = 0.001$; 14.5% vs. 4.0%, $P = 0.000$, respectively). Negative expression of SATB2 and CDX2 was more common in *BRAF*-mutant CRC than in *BRAF* wild-type CRC (17.2% vs. 6.1%, $P = 0.003$; 13.8% vs. 4.2%; $P = 0.004$, respectively). There was no relationship between SATB2 and/or CDX2 negative expression and *KRAS*, *NRAS*, and *PIK3CA* mutations. The expression of p53 was not associated with MMR protein status or *BRAF*, *KRAS*, *NRAS* and *PIK3CA* mutations. In addition, the lack of expression of SATB2, CDX2, and p53 was associated with poor histopathological features of CRC. In conclusion, the lack of SATB2 and CDX2 expression in CRC was associated with MMR protein deficiency and *BRAF* mutation, but not with *KRAS*, *NRAS* and *PIK3CA* mutation. The expression of p53 protein was not related to the common molecular changes of CRC.

1. Introduction

Colorectal cancer (CRC) is a common malignant tumor of the digestive tract worldwide[1], and its occurrence is a complex process involving multiple genes and factors. At present, it is considered that sporadic CRC is primarily formed through two pathways. One is chromosomal instability, which is characterized by loss of heterozygosity and DNA aneuploidy, and is associated with *APC*, *KRAS*, and *TP53* mutations; the other is the microsatellite instability pathway, which is related to methylation of the promoter of the DNA mismatch repair gene *MLH1*, *BRAF* mutation, and CpG island methylation phenotype[2–4]. Molecular changes in CRC often potentially affect protein expression[4–8]. The AT-rich sequence-binding protein 2 (SATB2) and the caudal type homeobox transcription factor 2 (CDX2) are considered as specific immune protein markers of CRC[9–11]. SATB2 is a transcription factor that regulates chromatin remodeling and transcription. It is highly expressed in the lower gastrointestinal epithelium (including the appendix, colon, and rectum), specific neurons (cerebral cortex and hippocampus), osteoblast differentiated tumors, and the ductal epithelium of the testis and epididymis [12–14]. SATB2 exhibits high sensitivity to colorectal tumors, as >93% of the tumors are positive for this protein, although its level of expression and distribution vary[15]. Thus far, few studies have addressed the relationship between SATB2 protein expression and CRC-associated molecules. A limited number of studies have shown that SATB2 expression in CRC is associated with MMR protein deficiency and *BRAF* mutation[5, 6, 16]. Moreover, loss of SATB2 expression often occurs in MMR-deficient and *BRAF*-mutant colon cancer [5, 6]. In colitis-associated colorectal adenocarcinoma, the loss of SATB2 expression is not related to *KRAS* or *BRAF* mutation, or MMR protein deficiency[17, 18]. One possible explanation for this finding is that the formation of colitis-associated colorectal adenocarcinoma and sporadic CRC are based on different molecular changes[17].

During the process of clinicopathological diagnosis, SATB2 is often used in combination with CDX2 to diagnose the origin of colorectal adenocarcinoma or metastatic adenocarcinoma[9–11]. *CDX2* is a *Drosophila* tail related homeobox gene that encodes a transcription factor and plays an important role in intestinal development by inhibiting the proliferation and promoting the differentiation and expression of intestine-specific genes[19]. Ninety percent of CRC cases show strong CDX2 nuclear positivity. In a study of 713 cases of CRC, two different clones of an anti-CDX2 antibody were used for immunohistochemical detection, which each revealed that CDX2 expression was lost in 5.9% and 6.0% of cases, respectively [8]. Loss of CDX2 expression is closely related to molecular changes in CRC, such as the CpG island methylation phenotype (CIMP), microsatellite instability, and *BRAF* mutation[4–8]. Concomitantly, it was also found that the loss of CDX2 expression is associated with an aggressive tumor behavior and poor clinical outcomes[8]. The p53 tumor suppressor protein, which is encoded by the *TP53* gene, is involved in DNA damage repair, cell-cycle regulation,

apoptosis, and senescence[20]. Thus far, a limited number of articles have reported that the overexpression of p53 is negatively correlated with microsatellite instability (MSI)[21]; however, its relationship with other molecules is not clear.

Although previous studies have shown that the loss of SATB2 and CDX2 expression is associated with *BRAF* mutation and MMR protein deficiency in colon cancer [5, 6, 16], the relationship between SATB2 and the status of other molecules (such as *KRAS*, *NRAS*, and *PIK3CA* mutation) remains poorly understood. Moreover, most of those studies were based on the data collected from the Western population, and few reports have examined the Chinese population. In addition, the relationship between p53 expression and CRC-associated molecules warrants further study. To clarify the relationship between the expression of the SATB2, CDX2, and p53 proteins and CRC-associated molecules, we collected tissue samples from 1180 patients with CRC at the Fujian Provincial Hospital, China. Furthermore, to avoid the heterogeneity associated with tumor cell immune protein expression, we used whole-slide sections to evaluate the relationship between SATB2, CDX2, and p53 immunohistochemical expression, and MMR protein status, as well as *BRAF*, *KRAS*, *NRAS*, and *PIK3CA* mutations. This was the largest study in this field to use whole-slide immunohistochemistry and the simultaneous evaluation of the relationship between SATB2, CDX2, and p53 protein expression and CRC-associated molecules. In addition, this study is a supplement to the current lack of research data on the Chinese population.

Lastly, we further confirmed whether the loss of SATB2 and CDX2 expression was associated with MMR protein deficiency and *BRAF* mutation, but not with *KRAS*, *NRAS*, and *PIK3CA* mutation. Concomitantly, we found that the expression of the p53 protein was not associated with the common molecular changes of CRC.

2. Materials And Methods

2.1 Patient selection and case review

The clinicopathological data of 1180 cases of colorectal adenocarcinoma diagnosed at the Department of Pathology of the Fujian Provincial Hospital from January 2017 to January 2021 were retrospectively collected. The inclusion criteria were as follows: 1) all patients underwent surgical resection of CRC and were diagnosed with primary colorectal adenocarcinoma; 2) all cases had relatively complete clinical and pathological data; and 3) all cases were diagnosed by two gastrointestinal pathologists. The cohort included 752 males and 428 females and encompassed 231 cases of right colon cancer and 949 cases of left colon and rectum cancer. All tissue samples were fixed in 10% neutral formalin solution (pH 7.2) for 24 h, dehydrated routinely, embedded in paraffin, sectioned at 4 μ m, stained with hematoxylin and eosin, and observed. The trial was approved by the ethics committee of the hospital, and the patients voluntarily participated in the trial. All patients signed the informed consent form themselves. The initial operation type, demographic information, and clinical data were obtained from the electronic case system.

2.2 Histopathological evaluation

A histopathological evaluation was performed for all cases, and the histological characteristics of each case, including histological grade, pathological stage, lymphatic invasion, venous invasion, and nerve invasion, were then re-evaluated. All histological features were evaluated via routine hematoxylin and eosin staining. The tumor sites were divided into two types: right colon (including the ascending colon, hepatic flexure, and transverse colon), and left colon (including the splenic flexure, descending colon, and sigmoid colon) and rectum. A low grade was defined as gland formation >50%, and a high grade was defined as gland formation <50% and/or signet ring cell differentiation. Combined with the clinical data, all cases were classified according to clinical stage.

2.3 Immunohistochemical analysis

Immunohistochemical staining was performed using the EnVision two-step method. Antibodies for CDX2 (EPR2764Y, Fuzhou Maixin Biotech Co., Ltd, China), SATB2 (EP281, Fuzhou Maixin Biotech Co., Ltd, China), p53 (MX008, Fuzhou Maixin Biotech Co., Ltd, China), MLH1 (EPR3894, Abcam, UK), PMS2 (EPR3947, Abcam, UK), MSH2 (EPR21017123, Abcam,

UK), and MSH6 (EPR3945, Abcam, UK) were used in this experiment. On-slide tissue positive and negative controls were used for all cases. The immunohistochemical expression levels of SATB2 and CDX2 (Figure 1) were scored as reported previously[22]. For a negative score, two staining patterns were considered: a) complete loss of expression in tumor cells (score, 0); and b) a few tumor cells showed scattered and fuzzy nuclear expression (score, 1). For a positive score, two staining patterns were considered: a) strong staining in most tumor cells (score, 2); and b) strong staining in all tumor cells (score, 3). The expression of the p53 protein was defined as nuclear staining of tumor cells: a proportion of nuclear staining in tissue sections <10% was considered negative, whereas a proportion >10% was considered positive (Figure 2). For MLH1, PMS2, MSH2, and MSH6, the expression was defined as nuclear staining of tumor cells, using infiltrating lymphocytes and surrounding nontumor intestinal mucosa as internal positive controls. Loss of expression of the MLH1, PMS2, MSH2, and MSH6 proteins was defined as complete absence of nuclear staining within tumor cells, whereas positive signals were detected in the non-neoplastic area of the intestinal mucosa. The absence of MMR protein expression was defined as the nuclear expression of all four MMR proteins. Deficient MMR protein expression was defined as the loss of expression of at least one of the four MMR proteins. Proficient MMR protein expression was defined as preserved nuclear expression of all four MMR proteins.

2.4 Molecular mutation analysis

BRAF, *KRAS*, *NRAS*, and *PIK3CA* mutation analysis was performed in paraffin-embedded tissue samples. Typical paraffin blocks were selected and cut into 10 pieces of 10 μm . The cut tissue was placed in a 1.5 ml centrifuge tube. DNA was extracted from paraffin sections according to the instructions of a nucleic acid extraction or purification kit (Xiamen Eide Biomedical Technology Co., Ltd., China). The collected DNA samples were stored at $-20\text{ }^{\circ}\text{C}$. According to the steps shown in the manual of the human *KRAS/NRAS/BRAF/PIK3CA* multi gene mutation joint detection kit (Xiamen Eide Biomedical Technology Co., Ltd., China), samples were prepared and detected via real-time fluorescent quantitative PCR. The amplification procedure was as follows: first stage: one cycle of $95\text{ }^{\circ}\text{C}$ for 5 min; second stage: 15 cycles of $95\text{ }^{\circ}\text{C}$ for 25 s, $64\text{ }^{\circ}\text{C}$ for 20 s, and $72\text{ }^{\circ}\text{C}$ for 20 s; and third stage: 31 cycles of $93\text{ }^{\circ}\text{C}$ for 25 s, $60\text{ }^{\circ}\text{C}$ for 35 s, and $72\text{ }^{\circ}\text{C}$ for 20 s. The mutation detection sites included *KRAS* exon 2 (G12D, G12A, G12V, G12S, and G12C), *KRAS* exon 3 (Q16H), *NRAS* exon 2 (G12D), *NRAS* exon 3 (Q61R, Q61K), *BRAF* exon 15 (V600E), and *PIK3CA* exon 21 (H1047). Molecular detection in resected tumors is part of the routine evaluation performed at the Fujian Provincial Hospital, and is carried out at the initial pathological evaluation.

2.5 Statistical analysis

The Excel software was used to screen, classify, and summarize the data. Statistical analyses were performed using SPSS for Windows 22 (IBM, Armonk, NY). The χ^2 or Fisher's exact tests were used to characterize the relationship between categorical variables. The Kruskal–Wallis test was used to characterize the relationship between continuous variables. The disordered variables were evaluated by two-sided tests, and the ordered variables were evaluated by one-sided tests. *P*-values <0.05 were considered statistically significant.

3. Results

3.1 Negative expression of SATB2, CDX2, and p53 was correlated with poor histopathological features of CRC

Among the 1180 cases of CRC, 78 cases (6.6%) were negative for SATB2 immunohistochemical expression. Compared with SATB2-positive tumors, SATB2-negative tumors exhibited more adverse histological features (Table 1), including a high tumor grade (28.2% vs. 15.5%, *P* = 0.003), neural invasion (47.4% vs. 33.1%, *P* = 0.010), vascular invasion (51.3% vs. 39.5%, *P* = 0.040), lymphatic invasion (51.3% vs. 35.1%, *P* = 0.004), pN2 stage (24.4% vs. 12.7%, *P* = 0.004), pM1 stage (15.4% vs. 6.5%, *P* = 0.004), 003), and later clinical stage (stage III–IV) (52.6% vs. 38.1%, *P* = 0.011). There was no

significant difference in age, tumor diameter, gender, tumor location, and pT stage among these two types of tumor ($P > 0.05$).

Table 1

Clinicopathological features of colorectal cancer stratified according to SATB2, CDX2, and p53 immunohistochemical expression

Clinical and Pathologic Features	SATB2		P	CDX2		P	p53		P
	Negative	Positive		Negative	Positive		Negative	Positive	
age (year)	63.5(55.0-72.0)	64(56.0-71.0)	0.757	63(55.0-71.0)	64(56.0-71.0)	0.446	63(56.0-71.0)	64(56.0-71.0)	0.269

Tumor grade			0.003			0.025			0.001
High tumor grade	22(28.2)	171(15.5)		15(27.3)	178(15.8)		71(22.1)	122(14.2)	
Low tumor grade	56(71.8)	931(84.5)		40(72.7)	947(84.2)		250(77.9)	737(85.8)	

Among the 1180 cases of CRC, 55 cases (4.7%) were negative for CDX2 immunohistochemical expression. Similar to that observed for SATB2, CDX2-negative expression was associated with poor histological features (Table 1). Compared with CDX2-positive tumors, CDX2-negative tumors exhibited a high tumor grade (27.3% vs. 15.8%, $P = 0.025$), vascular invasion (56.4% vs. 39.5%, $P = 0.013$), lymphatic invasion (52.7% vs. 35.4%, $P = 0.009$), pM1 stage (18.2% vs. 6.6%, $P = 0.004$), and later clinical stage (III–IV) (54.5% vs. 38.3%, $P = 0.016$) more often. There was no significant difference in age, tumor diameter, gender, nerve invasion, tumor location, pT stage, and pN stage between these two types of tumor ($P > 0.05$).

Among the 1180 cases of CRC, 321 cases (27.2%) were negative for p53 immunohistochemical expression. Compared with p53-positive tumors, p53-negative tumors showed a higher tumor grade (22.1% vs. 14.2%, $P = 0.001$). There was no significant difference in age, tumor diameter, gender, tumor location, nerve invasion, vascular invasion, lymphatic invasion, pT, pM, pN stage, and clinical stage among these two types of tumor ($P > 0.05$).

3.2 The SATB2 and CDX2 expression pattern was associated with MMR protein deficiency and the BRAF V600E mutation

SATB2 and CDX2 immunohistochemical expression was significantly affected in MMR-protein-deficient and *BRAF*-mutant CRC (Table 2). Negative SATB2 and CDX2 expression was observed significantly more often in MMR-protein-deficient CRC compared with MMR-protein-proficient CRC (15.8% vs. 6.0%, $P = 0.001$; 14.5% vs. 4.0%, $P < 0.001$, respectively) (Figure 3). Negative SATB2 and CDX2 expression was observed significantly more often in *BRAF* V600E mutated tumors compared with *BRAF* wild-type tumors (17.2% vs. 6.1%, $P = 0.003$; 13.8% vs. 4.2%, $P = 0.004$, respectively) (Figure 3). Immunohistochemical expression of SATB2 and CDX2 was not altered in *KRAS*, *NRAS*, and *PIK3CA* mutated CRC.

Table 2
SATB2, CDX2, and p53 expression in colorectal cancer stratified according to mismatch repair protein immunohistochemistry and *BRAF*, *KRAS*, *NRAS*, and *PIK3CA* mutation

3.3 Effects of MMR protein status and *BRAF* mutation on the combined expression profile of SATB2 and CDX2 in CRC

SATB2 and CDX2 combined immunohistochemical expression profiles were also affected by MMR protein and *BRAF* mutation status (Table 3). In fact, 27.6% of SATB2-negative and/or CDX2-negative tumors (including 13.2% SATB2⁻/CDX2⁺, 11.8% SATB2⁺/CDX2⁻, and 2.6% SATB2⁻/CDX2⁻) were found among MMR-protein-deficient CRC samples. Only 9.2% of the tumors that were proficient for MMR proteins were SATB2-negative and/or CDX2-negative tumors ($P < 0.001$). Moreover, 25.9% of *BRAF* V600E mutated CRC cases were found to be SATB2-negative and/or CDX2-negative tumors, (including 12.1% SATB2⁻/CDX2⁺, 8.6% SATB2⁺/CDX2⁻, and 5.2% SATB2⁻/CDX2⁻). Only 9.5% of *BRAF* wild-type tumors were SATB2-negative and/or CDX2-negative tumors ($P < 0.001$).

Table 3

Combined SATB2 and CDX2 immunohistochemistry expression profiles in colorectal cancer stratified according to mismatch repair protein and *BRAF*, *KRAS*, *NRAS*, and *PIK3CA* mutation

3.4 The expression pattern of the p53 protein was independent of the common molecular changes of CRC

The expression of the p53 protein was not associated with MMR protein deletion or *BRAF*, *KRAS*, *NRAS*, and *PIK3CA* mutations in cases of CRC.

4. Discussion

In this study, whole-slide immunohistochemistry was used to evaluate the association between SATB2, CDX2, and p53 immunohistochemical expression in cases of CRC and MMR protein deficiency, as well as *BRAF*, *KRAS*, *NRAS*, and *PIK3CA* mutations. Our results showed that the immunohistochemical expression of SATB2 and CDX2 was affected by molecular changes in CRC, and that negative SATB2 and CDX2 expression was more common in MMR-protein-deficient CRC and *BRAF*-mutant CRC, but not in *KRAS*, *NRAS*, and *PIK3CA*-mutant CRC. The immunohistochemical expression of p53 was not associated with molecular changes in CRC. In addition, we observed that negative expression of SATB2, CDX2, and p53 was associated with poor histopathological features of CRC.

Thus far, few studies have addressed the relationship between SATB2 protein expression and molecules commonly associated with CRC. Ma et al.[5] analyzed 499 cases of colon cancer and observed negative SATB2 and/or CDX2 expression in 33% of MMR-protein-deficient tumors and 36% of *BRAF* V600E-mutant tumors. This result is similar to that

obtained in our study (Table 2). In addition, those authors found that the negative expression of SATB2 was associated with a low disease-specific survival rate among MMR-protein-deficient cases of colon cancer[5]. In their study, the negative expression rate of SATB2 (67/499, 13%) was higher than that detected in our study (78/1180, 6.6%). Eberhardt et al.[23] analyzed 527 cases of colon cancer and also observed that SATB2 expression was often absent in MMR-protein-deficient tumors; moreover, negative expression of SATB2 can be used as an independent predictor of a decreased disease-specific survival rate among patients with colon cancer. In their study, the negative expression rate of SATB2 was 28.8% (152/527), which was much higher than that detected here. We propose the following explanations for this discrepancy: first, compared with Ma et al. (499 cases) and Eberhardt et al. (527 cases), our study included a larger sample (1180 cases) because it included cases of rectal cancer. Second, different antibody clones were used in each study, which may explain the differences in SATB2 expression detected in the samples of CRC. In addition, the definition of negative expression of SATB2 was slightly different. Further, we used the whole-slide immunohistochemistry method, rather than the tissue microarray method, to analyze the expression of SATB2. Cigerova et al. [16] observed that the SATB2 protein was absent only in 7.2% of CRC cases. This is similar to our results. In addition, our study found that negative SATB2 expression was not associated with *KRAS*, *NRAS*, and *PIK3CA* mutation status. This is rarely mentioned in the remaining pertinent literature. Our study did not evaluate the survival and prognosis of patients with CRC because of an insufficient follow-up time. This also requires the inclusion of a long-term follow-up of the patients in future work to improve the quality of the data, and thus further determine the impact of negative SATB2 expression on the prognosis of patients with CRC. It was recently reported that expression of SATB2 is also frequently absent in colitis-associated colorectal adenocarcinoma; however, the loss of SATB2 is not related to *BRAF* mutation and MMR protein deficiency[17, 18]. One possible explanation for this finding is that the formation of colitis-associated colorectal adenocarcinoma may be triggered by a continuous inflammatory environment, which induces epithelial DNA mutation[17] and is different from the mechanism underlying sporadic CRC. In addition, we observed that SATB2 negative expression was associated with poor histopathological features in patients with CRC, including a high tumor grade, neural invasion, vascular invasion, lymphatic invasion, and later pathological and clinical stage. These results are consistent with the literature[5, 6, 23, 24].

Previous studies have shown that the loss of CDX2 expression is closely related to the molecular changes of colorectal cancer[4–8, 25, 26]. Lugli et al.[4] observed that CDX2 was more likely to be lost in MMR-protein-deficient colorectal cancer than in MMR-protein-proficient CRC. Subsequently, Ma et al. [6] further confirmed that CDX2 expression is often absent in MMR-protein-deficient and *BRAF*-mutant colon cancer. Most of those studies did not mention the relationship between CDX2 and *KRAS*, *NRAS*, and *PIK3CA* mutation. We observed that the expression of CDX2 was not affected by the mutation status of *KRAS*, *NRAS*, and *PIK3CA* in patients with CRC. In a study of 713 cases of CRC, Bae et al.[8] used two different clones of an anti-CDX2 antibody (CDX2-88 and EPR2764Y) and found that the CDX2 negative expression rates were 5.9% (CDX2-88) and 6.0% (EPR2764Y). This was similar to our study (55/1180, 4.7%). Olsen et al.[25] conducted a qualitative systematic review of 52 studies of CDX2 expression in CRC. They observed that the loss of CDX2 expression was related to tumor grade, tumor stage, right tumor location, MMR deficiency, high CIMP, and *BRAF* mutation. Similar results were observed in our study.

Although SATB2 and CDX2 are often negatively expressed in CRC cases with MMR protein deficiency and *BRAF* mutation, their expression is different. Concurrent negative SATB2 and CDX2 expression (SATB2–/CDX2–) was only rarely observed as it was identified in 2.6% of MMR-protein-deficient and 5.2% of *BRAF*V600E-mutant CRC samples. Therefore, the losses of SATB2 and/or CDX2 expression are independent from each other in most cases of CRC with MMR protein deficiency and *BRAF* mutation. This is similar to that reported by Ma et al.[5, 6]. Therefore, when the morphology of CRC is not typical, the combination of SATB2 and CDX2 can help establish a correct diagnosis and avoid misdiagnosis, especially in MMR-protein-deficient and *BRAF*-mutant tumors. The reason for the loss of SATB2 and CDX2 expression in MMR-protein-deficient and *BRAF*-mutant CRC remains unclear. Some studies have suggested that epigenetic silencing caused by a high level of CpG island promoter methylation may be a mechanism of CDX2 expression reduction[7, 27, 28]. In addition, CDX2 plays an important role in the regulation of the polarity of epithelial cells, and the loss of CDX2 may be related to the

interruption of epithelial tight junction and epithelial mesenchymal transition (EMT) [27, 29]. There are also studies that suggest that reduced CDX2 expression is caused by a passenger mutation in the simple repeat sequence of the *CDX2* gene[30]. It is not clear whether the reduced SATB2 expression occurs via the same mechanism as CDX2. Ma et al.[6] proposed that alternative mechanisms lead to the loss of SATB2 expression, as only 14% of MMR-protein-deficient tumors exhibited concurrent loss of CDX2 and SATB2 expression. Our results also support this view.

The results of our study show that the negative expression of the p53 protein is not associated with MMR protein deficiency or *BRAF*, *KRAS*, *NRAS*, and *PIK3CA* mutations in patients with CRC. In the study reported by Elsaleh et al.[21], overexpression of the p53 protein in CRC was negatively correlated with microsatellite instability (MSI). In our study, we did not find that the expression of p53 protein was related to the DAN MMR protein. Cao et al.[20] observed that the loss of p53 expression was related to invasive clinicopathological features among patients with colon cancer, including age distribution, tumor course, tumor location, tumor diameter, tumor invasion depth, Dukes stage, distant metastasis, and lymph node metastasis. We observed that the loss of p53 expression was only related to tumor grade.

This study has some limitations, e.g., the inclusion and screening of cases using a retrospective design and the heterogeneity of protein expression in tissue sections. However, the advantage of this study is that partial heterogeneity was solved using whole-slide immunohistochemistry, which also conferred considerable reliability to the negative expression of SATB2, CDX2, and P53. In addition, our study is one of the largest studies thus far that investigated the negative expression of SATB2, CDX2, and p53 and molecular changes in CRC using whole-slide immunohistochemistry. Our study is a representative of CRC resected at a large academic medical center in Fujian Province, China; therefore it has an inherent referral bias.

In conclusion, our results suggest that negative SATB2 and CDX2 expression is associated with MMR protein deficiency and *BRAF* mutation, but not with *KRAS*, *NRAS*, and *PIK3CA* mutation, in patients with CRC. In addition, negative p53 expression is not associated with the common molecular changes of CRC.

Declarations

Contributions:

J-ZL and QZ researched the data, wrote and edited the manuscript. H-JH, L-FC and X-YQ performed the statistical analysis. All authors read and approved the final manuscript.

Conflict of interest:

The authors declare that they have no conflict of interest.

All authors participated sufficiently in the work to take public responsibility for the content, including participation in the concept, design, analysis, writing, or revision of the manuscript. In addition, each author certifies that this material or similar material has not been and will not be submitted to or published in any other publication.

Disclosure of funding:

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Ethics declarations:

The study complied with the Helsinki Declaration, and the study protocol and exemption of informed consent were approved by the Institutional Ethics Committee of Fujian Provincial Hospital, Fuzhou, China (K2021-09-042).

Consent for publication:

Not applicable.

Acknowledgements:

Not applicable.

Availability of data and materials:

The datasets generated and/or analyzed in the present study are available from the corresponding author on reasonable request.
